The extension of previous work consists of an analysis of the markets for operator labor and unpaid family labor. Previous econometric studies of the agricultural labor market have tended to concentrate on the hired component, although Johnson and Heady [12] have done some analysis of the other components—particularly on the demand side.

The modification in the analytical model consists of attempting to take account of the interdependence among the various components of the labor force. Previous studies have assumed that the market for hired labor, for example, could be analyzed independently of what takes place in the markets for operator and unpaid family labor. In this study, we hypothesize a six-equation simultaneous-equations model that takes account of the interrelationship among the three components. The model consists of demand and supply equations for each component, with price and quantity of all sectors assumed to be endogenously determined, subject to a set of exogenous variables.

Edward Schuh *is professor of agricultural economics at Purdue University and program advisor in agriculture, Ford Foundation, Brazil.*

The Conceptual Model

The basic economic model used in this study hypothesizes that the quantity of labor supplied to agriculture depends upon wages, alternative income opportunities, and the size of the civilian labor force. On the demand side, it is hypothesized that farm operators (1) accept as given the prices they must pay for inputs other than labor and the prices they receive for their products, and (2) adjust their use of labor in the light of these prices, the price of labor, and the technological alternatives open to them in production.

As a first approximation, then, the supply equations express farm employment as a function of real wages of farm labor, a measure of the income earned in nonagricultural employment, the amount of unemployment in the economy (which affects the availability of alternative income opportunities), and the size of the civilian labor force. The demand equation expresses farm employment as a function of real wage rates of farm labor, an index of the prices of agricultural products, an index of the prices of other inputs, and a measure of technology.

Certain conceptual issues arise when this general kind of model is applied to such widely differing components of the farm labor force as hired labor, unpaid family labor, and operator labor. Among these issues are the following:

1. *The degree of interaction or interdependence among the three components of the farm labor force.* Previous studies of the hired farm labor force [19, 20, 23, 12] have assumed that the market for each component could be studied independently of the others. However, substitution and change of category may take place on both the demand and supply sides of the markets, thereby leading to substantial interdependence. For example, the supply of unpaid family labor may affect the demand for hired labor, or the demand for hired labor may affect the supply of unpaid family labor.

In order to test for this interdependence, "substitution" variables were introduced into the demand and supply equations for each component. These substitution variables are the levels of employment of the other components of the labor force and are treated as endogenous or jointly determined.[3]

2. *The appropriate "price" for agricultural labor.* A number of factors are involved. First, the models were developed to explain annual employ-

---

[3] Ideally, one would like to introduce the "price" of the other components in analyzing these substitution relationships. However, lack of information on the price of the several components (see below), particularly unpaid family labor, led to our use of the quantity variables. We recognize the theoretical limitations of this approach, but feel that the empirical insights gained outweigh the disadvantage of not having a theoretically pure substitution effect.

ment in year equivalents of labor (an average of the monthly employment). This suggests that some concept of annual labor income in agriculture may be appropriate. However, given the short period of employment for much of the hired and unpaid family labor, an index of wage rates may be more appropriate. Further support is given to this choice, at least for hired labor, when it is recognized that the USDA series on expenditure on hired labor, from which an annual concept could be developed, uses the index of wage rates for intercensal interpolation.

A second factor has to do with the price for unpaid family labor and operator labor. By definition, no fixed wage or salary is paid to unpaid family labor, which receives its compensation as it participates in the returns to the farm family. A similar issue arises in the comparison between unpaid family labor and operator labor. No evidence is available on the extent to which unpaid family labor shares in the total labor return to the farm.

If the labor market functioned perfectly and the quality of labor were the same among all three components of the labor force, the agricultural wage rate could serve as a proxy for the price of labor in each component. To bring some statistical evidence to bear on this question, a measure of net farm income attributable to the family labor force was calculated by charging opportunity costs to the other inputs and calculating the return to labor as a residual. Two estimates of the price of family labor were obtained by alternatively dividing this by the year equivalents of family labor (unpaid family plus operator) and by the number of farms (our estimate of the number of farm operators). Experiments were made with these and the agricultural wage rate in estimating the models for unpaid family labor and operator labor.

Computing the return to family labor as a residual in this way assumes that most of the risk and uncertainty of the income stream in agriculture is borne by the farm operator as a labor owner, or by his family. In contrast, the use of the wage rate would impute most of this risk to the fixed capital assets. The truth probably lies someplace between, but it is not possible to arrive at it empirically.

3. *The market for operator labor.* Once again, a number of problems are involved. First, the farm operator generally owns a number of assets, only one of which is the labor he can supply. Consequently, it might be argued that the number of farm operators (and the quantity of operator labor supplied) is determined not only by the return to labor, but also by the return to the other factors owned, such as land and capital. In this study it was assumed that the market for the several inputs was sufficiently perfect that the level of employment of farm operators could be explained by labor returns.

A second problem has to do with the way in which the demand for operator labor is formulated. Some have argued [for example, 11] that the farm operator might demand more of his own labor services as the return to it increases. This, in effect, would result in a positively sloping demand curve.

In this analysis, we have assumed that the individual farm operator plays two roles and is involved in essentially two decision making processes. As an entrepreneur, he can choose and combine inputs in an optimum economic manner; consequently, he will demand less of an input as its price rises relative to the price of other inputs. As the owner of an asset, on the other hand, he is interested in employing it where it will receive the highest return. Consequently, as the returns to labor in one industry rise relative to those in another, he transfers his employment to another, thereby increasing the supply of labor in the latter. This is a supply phenomenon, however; not a demand phenomenon.

Based on these considerations, a negative relationship is hypothesized between the price of operator labor and the quantity demanded, as for the other two components of the farm labor force. In this formulation an attempt is made to identify the demand and supply forces at work in the market.

4. *The employment alternatives considered by farm operators.* Previous work with hired farm labor has hypothesized that labor, upon leaving agriculture, goes into a wide variety of nonfarm employments [19, 23]. Consequently, a broad-based measure of nonfarm income per employed worker in the nonfarm sector has been used as the income alternative. This probably applies directly to unpaid family labor also, but it might be argued that operator labor, with its entrepreneurial skills, goes into other entrepreneurial activities. However, the limited evidence available [21] suggests that off-farm migrants as a class tend to work as craftsmen and foremen, operatives, and laborers rather than to engage in other entrepreneurial activities. For this reason the same measure of nonfarm income alternatives was used for farm operators as for the other two components of the farm labor force.

The Statistical Model and Estimation Procedure

The basic statistical model assumes that the level of employment and price of labor for each component of the farm labor force are determined in a market that can be described by a demand and supply equation. These markets are assumed to be interdependent or jointly dependent. Hence, the model is a six-equation simultaneous system.

Nerlove type distributed lags [13, 14] were introduced into each equation, on the assumption that demanders and suppliers of farm labor do not adjust immediately to changing economic conditions but rather spread their adjustment over time. This permits the derivation of both long-run and short-run elasticities.

A trend variable was included in the specification of all demand and supply functions for two reasons. First, it provides a test for secular influences in the labor market that are not explicitly taken into account by the other variables. On the demand side, these would include such factors as the changing quality of the labor force, secular shifts in preferences on the part of employers, and institutional and other changes in the total economy. On the supply side, part of the secular flow of labor out of agriculture may be explained by a gradual change in tastes and preferences for employment in specific industries, the effect of increased schooling on mobility, secular improvements in communication and transportation, or the development and expansion of a more well-integrated economy.

Second, addition of the trend variable improves the specification of the distributed lag model. It has been shown that the coefficient of the lagged dependent variable is especially susceptible to specification bias [1, 10]. If the trend variable picks up the effects of omitted variables that are highly correlated with time (these are most likely to cause problems), the bias should be at least reduced.

Time series data for 1929–61 were used in fitting the model.[4] The data were converted to logarithms for fitting; hence, the estimated coefficients provide direct estimates of the elasticities. Theil-Basmann (two-stage least squares) estimating procedures were used in order to account for the simultaneity in the system.

The basic statistical model is summarized by the following six equations:[5]

$Y_1 = a_1 + b_1 Y_2 + b_2 Y_3 + b_3 Y_5 + b_4 X_2 + b_5 X_6 + b_6 X_4 + b_7 X_9 + \mu_1$ (demand for hired labor)

$Y_1 = a_2 + b_8 Y_2 + b_9 Y_3 + b_{10} Y_5 + b_{11} X_5 + b_{12} X_{10} + b_{13} X_4 + b_{14} X_9 + \mu_2$ (supply of hired labor)

$Y_3 = a_3 + b_{15} Y_4 + b_{16} Y_1 + b_{17} Y_5 + b_{18} X_2 + b_{19} X_6 + b_{20} X_{11} + b_{21} X_9 + \mu_3$ (demand for unpaid family labor)

$Y_3 = a_4 + b_{22} Y_4 + b_{23} Y_1 + b_{24} Y_5 + b_{25} X_5 + b_{26} X_{10} + b_{27} X_{11} + b_{28} X_9 + \mu_4$ (supply of unpaid family labor)

$Y_5 = a_5 + b_{29} Y_6 + b_{30} Y_1 + b_{31} Y_3 + b_{32} X_2 + b_{33} X_3 + b_{34} X_{12} + b_{35} X_9 + \mu_5$ (demand for operator labor)

$Y_5 = a_6 + b_{36} Y_6 + b_{37} Y_1 + b_{38} Y_3 + b_{39} X_5 + b_{40} X_{10} + b_{41} X_{12} + b_{42} X_9 + \mu_6$ (supply of operator labor)

where

---

[4] A description and evaluation of the data, plus the data used in estimation, are available from the authors.

[5] Variable identification used in previous published work by the authors has been preserved in order to facilitate comparison by the interested reader.

Y_1 = hired farm labor, measured in year equivalents (USDA estimates);
Y_2 = index of composite wage rates in agriculture, deflated by the consumer price index;
Y_3 = unpaid family labor, measured in year equivalents (USDA estimates of family labor minus the number of farms);
Y_4 = net farm income to family labor per family worker, deflated by the consumer price index;
Y_5 = operator labor, measured as the USDA estimates of number of farms;
Y_6 = net farm income to family labor per farm operator, deflated by the consumer price index;
X_2 = the index of prices received by farmers for all products, deflated by the index of prices paid by farmers for items used in production, except labor ("real" farm prices)[6];
X_4 = hired farm labor, lagged one year;
X_5 = the size of the civilian labor force;
X_6 = Ruttan's [17] index of technology;
X_9 = a trend variable ($1929=1$, $1930=2$, etc.);
X_{10} = nonfarm income per employed worker in the nonfarm sector, multiplied by the percent of the labor force employed and deflated by the consumer price index (this is an estimate of the "expected" average annual income for nonfarm employment);
X_{11} = unpaid family labor, lagged one year;
X_{12} = operator labor, lagged one year; and
μ_i = random error term ($i=1, 2, \cdots, 6$).

Considerable experimenting with the model was done in order to test alternative formulations and to evaluate alternative measures of the economic concepts. The procedure followed was to initiate the work with the markets for unpaid family labor and operator labor, since previous research had dealt with the hired labor component. In this initial work, the markets for unpaid family and operator labor were treated as independent two-equation models. The levels of employment for the other components were introduced as exogenous variables.

After suitable models of these markets were obtained, the markets for hired labor, unpaid family labor, and operator labor were integrated into the six-equation model, which explains simultaneously the price and level of employment for each component of the farm labor force, subject to the set of exogenous variables. In this model, the levels of employment for each component were treated as endogenous variables.[7]

---

[6] Because of the serious conceptual and statistical difficulties in measuring the prices of other inputs, especially when they are capital goods, a broad index of the price of non-labor inputs was used and introduced into the model as a deflator of the prices received for farm products. In this way the effect of these price changes is accounted for, but in a rather aggregative way. This is true of each demand equation.

The basic experiments with the models were as follows:

1. *A search for interdependencies among the components.* This was done by introducing separate variables for each of the other components, then omitting those that did not have statistically significant coefficients.

2. *An attempt to identify the role of technology in the labor market.* Considerable work was addressed to this problem with disappointing results. Technology was introduced both as an exogenous variable, as it had been treated in earlier studies, and as an endogenous variable with interrelationships with the price of agricultural labor postulated. None of these experiments was successful.

3. *The estimation of both dynamic (distributed lag) and static models.* This was done by omitting the lagged dependent variable. The evidence in support of the distributed lag hypothesis was reasonably strong, except for operator labor.

4. *The testing of alternative "prices" of farm labor.* Those tested were farm wage rates, net farm income to family labor per family worker, and net farm income to family labor per farm operator. Each was used in estimating the demand and supply equations for operator labor and for unpaid family labor.

Statistical Results

Space does not permit presentation of the statistical results of all these experiments.[8] Table 1 is based on the results generated by a distributed lag model with technology excluded. This model was selected as the "best" on the basis of the authors' judgment of such factors as the consistency of coefficient signs with a priori expectations, the statistical significance of the coefficients, the R^2, and the lack of serial correlation among the calculated residuals.

In general, the statistical results for this model were good. The signs of the coefficients were all consistent with the theory underlying the model. With few exceptions (notably the civilian labor force), the coefficients were also statistically significant at the five percent level or better. The explanatory power of each equation was adequate. Although the magnitude of the coefficients varied among the three components, they were consistent with the underlying economic theory.

However, some problems were encountered with the coefficient of the lagged dependent variable in both the demand and supply equations for

---

[7] A market clearing identity of quantity demanded equals quantity supplied was utilized in examining the interrelations among the various components of the labor force.

[8] See the original study [22] for these results.

[b] d' is the Durbin-Watson statistic for serial correlation among the calculated residuals. No superscript indicates no serial correlation; * indicates an inconclusive test; and ** indicates positive serial correlation.

operator labor. This coefficient was greater than one, although not significantly so.[9] This implies a negative coefficient of adjustment and suggests that there tends to be an over-adjustment to changing economic conditions in the market for operator labor. We view this coefficient with caution, however, because the Durbin-Watson statistic indicates serial correlation in the calculated residuals of both equations, suggesting that the coefficients of the lagged dependent variable might be seriously biased.

Attempts were made to correct this problem both by taking first differences of the variables and refitting, on the assumption that the error term was being generated by a first-order Markov process with a p of one[10] and by using the Durbin-Watson statistic to estimate the serial correlation, introducing this into the model explicitly by an appropriate differencing.[11] Neither procedure improved the statistical results.

Two final comments regarding the statistical results: First, all of the equations in the model in Table 1 satisfy the necessary and sufficient conditions for identification. Second, although intercorrelation among some of the independent variables was high because of the strong trend element in some of these variables, statistically significant coefficients nevertheless were obtained.

Economic Implications

Besides providing quantitative estimates of the demand and supply functions for the three types of farm labor, this study provided a test of the applicability of the theory of demand for a factor of production and the theory of supply of labor to an industry by estimating basically the same model for all three components of the agricultural labor force.

Implications of the results obtained will be presented in two parts: (1) a discussion of the general economic implications, (2) an analysis of the elasticities and their differences among the components. The elasticities derived from the model presented in Table 1 are given in Table 2.

General economic implications

The general economic model set forth for the demand and supply of the components of the farm labor force was quite successful in this study. The coefficient of the price of labor variable was negative and statistically significant in all three demand functions and positive and statistically significant in all three supply functions. Thus, an increase in the farm wage

---

[9] Confidence intervals were used for this test in order to make two statistical inference operations at the same time. It was desired to test whether the coefficient was significantly differnt from both zero and one.

[10] See [4] for an explanation of this as a viable alternative.

[11] As suggested by [9]

Table 2. Elasticities of adjustment and short-run and long-run elasticities

Model	Elasticity of adjustment	Price of labor[a]		Real farm prices		Civilian labor force		Nonfarm income adjusted for unemployment		Substitution[b] variable	
		S.R.	L.R.	S.R.	L.R.	S.R.	L.R.	S.R.	L.R.	S.R.	L.R.
Hired labor:											
Demand	.53	−.261	−.492	.310	.585					−.115[c]	.217[c]
Supply	.42	.649	1.545			.764	1.819	−1.419	−3.379	.318	−.757
Unpaid family labor:											
Demand	.14	−.420	−3.000	.559	3.993					−1.063	−7.593
Supply	.45	.681	1.513			.237[c]	.527	−1.466	−3.258	−.645	−1.433
Operator labor:											
Demand	—[d]	−.069		.066						−.202	
Supply	—[d]	.005				.023[c]		−.086		−.199	

[a] Farm wage rate in all equations, except operator labor supply where net farm income to family labor per farm worker was used.

[b] For hired labor demand, quantity of operator labor; for hired labor supply, quantity of unpaid family labor; for all others, quantity of hired labor.

[c] Computed from coefficients not significant at the 5 percent level or better.

[d] Coefficients of lagged dependent variable greater than one, implying a negative elasticity of adjustment, which is inconsistent with the distributed lag hypothesis. Consequently, long-run elasticities are not derived.

rate relative to the price of other inputs in agriculture was associated with a decrease in the quantity demanded of all types of farm labor, other things being equal. On the supply side, an increase in the returns to labor in agriculture relative to nonfarm income was associated with an increase in the quantity of farm labor supplied, other things being equal. In the short run, all of the responses were inelastic. With the exception of operator labor (where different measures of price were used in the demand and supply functions), the quantity supplied was more responsive to changes in the price of labor than the quantity demanded.

The nonfarm income variable[12] had a negative coefficient that was statistically different from zero in all three supply equations and appeared to be a strong shifter in every supply equation. The short-run elasticity was greater than the absolute value of -1 for the hired and unpaid family labor components, implying that a given increase in nonfarm income relative to farm wage rates would result in a proportionally larger decline in the quantity of labor supplied to agriculture, *ceteris paribus*. In addition, this elasticity was more than double that of agricultural wages for the hired and unpaid family labor markets. For operator labor the difference was much greater, implying that members of the agricultural labor force are more responsive to changes in nonfarm income than to changes in returns to agricultural labor. Part of this difference may be due to the fact that a wage rate concept is used in agriculture and an income concept is used for the nonfarm sector; however, the difference is even greater when income concepts are used in both sectors (operator labor supply), indicating that the differences are not simply the result of different measurement concepts.

If wage rates and incomes in the nonfarm sector continue to increase, the supply curves for the three types of farm labor will shift to the left. Since the comparable demand curves are generally more inelastic, these leftward shifts of the supply curves have a sizable impact in raising labor incomes in agriculture.

The real farm prices variable had the expected positive sign and was statistically significant in all three demand functions. The short-run elasticity of quantity of farm labor demanded with respect to real farm prices was less than one. An interesting relationship exists between the magnitude of the real farm prices coefficient and the price of labor coefficient; the larger the coefficient of real farm prices, the larger is the coefficient of the price of labor, and vice versa.

---

[12] As constructed, this variable measures the expected income to be received in the nonfarm sector on the assumption that the migrant receives the average compensation in the nonfarm sector if employed and zero income if unemployed. The probability of being unemployed is assumed to be given by the rate of unemployment in the general economy.

Although the technology variable was not used in this analysis because of less than adequate statistical results, this does not mean that technology does not have an impact on the demand for agricultural labor. It has been suggested[13] that adoption of new technology has its impact indirectly through the product market, rather than by reducing the demand for farm labor directly. Assuming that new technology is output increasing, farmers in a purely competitive market will employ new technology and produce a larger volume of output from a given bundle of inputs. When all farmers take this action, farm product prices will fall, *ceteris paribus*, especially in the light of the inelastic demand for farm products.[14] This decline in product prices will result in a leftward shift of the demand curve for farm labor and, consequently, a decline in farm wage rates, other things being equal. Thus, the effect of technology is transmitted to the farm labor market through the relative decline in farm product prices.[15]

The coefficient for the civilian labor force was positive in every case, but statistically significant only in the supply function for hired labor.[16] The response of quantity of labor supplied with respect to changes in the civilian labor force was inelastic in the short run for all three components. This indicates that increases in the civilian labor force, other things being equal, result in a less than proportional increase in the quantity of labor supplied to agriculture.

The trend variable appears to be an important shifter of both the demand for and supply of the three components of the agricultural labor force. The persistent negative coefficient on the trend variable indicates that whatever it is measuring is having a negative influence over time; that is, less labor is being demanded in and supplied to agriculture, *ceteris paribus*.

In the demand equations, the negative coefficient of the trend variable is consistent with the following interpretations: (1) It may be picking up the effects of technological change. This interpretation was not supported by the related statistical analysis, however. (2) It may be reflecting changes in the quality of farm labor over time [see 8]. As members of the farm labor force become better educated and perform more efficiently, fewer of them will be needed, *ceteris paribus.* (3) It may be picking up the effects of a consistent measurement error in some of the variables. Although there is no sound basis for choosing among these interpretations, the last two seem most plausible.

---

[13] See [20].

[14] For an analysis of the effect of technology on the demand for agricultural labor, using cross-sectional data, see [24].

[15] Two observations from our unreported work with technology are: (1) that the coefficient of the real farm prices variable tended to be smaller when technology was treated as an endogenous variable, and (2) that there was a rather consistent pattern of a negative coefficient for technology in the demand for hired and unpaid family labor, but a positive one in the demand for operator labor. The lack of a statistically significant coefficient for technology precluded our exploring these implications further.

[16] Farm population was tried as an alternative to the civilian labor force in the supply equations for unpaid family labor and operator labor. The statistical results were even poorer, however.

In the supply equations, the persistent negative coefficient of the trend variable is also subject to a number of interpretations: (1) It may be measuring the effects of a stronger preference for nonfarm employment, not only because of differences in relative incomes, but also because of better working conditions, shorter hours, or more prestige. (2) It may be picking up aspects of industrialization not included in the wage variables, e.g., availability of jobs, improved transportation systems, and improved communications. (3) As in the demand equations, it may be measuring the effects of consistent measurement or specification errors in some of the variables. (4) It may reflect the effect of increased schooling on mobility [see 8]. Again, we have no sound basis for choosing among these alternatives.

The coefficients of the substitution variables were negative in each equation and were statistically significant except in the hired labor demand equation. This indicates that an increase in the quantity of one component of the agricultural labor force will be associated with a decline in the demand for or supply of some other component, *ceteris paribus.* On the demand side, this implies that the components of the agricultural labor force may be substituted for one another in the production process; on the supply side, it indicates that members of the various components are to some extent mobile among the components of the agricultural labor force.

In general, the statistical results tend to support the distributed lag hypothesis, except for operator labor, where the coefficient of the lagged dependent variable is slightly, but not significantly, greater than one.[17] All of the coefficients for the lagged variables were significantly different from zero at the one percent level. This implies that there is a lag in the response to economic stimuli by members of the agricultural labor force.

Elasticities and differences among components

The economic implications of the elasticities obtained will now be discussed, together with some tentative explanations of the differences among the components of the agricultural labor force. The discussion will center around the coefficient of adjustment and the elasticities for the price of labor variable, the real farm prices variable, the civilian labor force variable, the nonfarm income variable, and the substitution variables.

---

[17] For a discussion of the limitations of the statistics used in evaluating the distributed lag hypothesis in the context of a study similar to the present one, see [23], especially pp. 547–549.

The elasticities of adjustment found in this study ranged from .53 in the hired labor demand equation to .14 in the unpaid family labor demand equation. This means that in the demand for hired labor the long-run elasticities are slightly less than twice the short-run elasticities. As a consequence, it would take about four years to remove 95 percent of the initial disequilibrium if no further disequilibrating changes occurred. An elasticity of adjustment of .14 implies that (1) the long-run elasticities are approximately seven times as great as the short-run elasticities in the demand function for unpaid family labor, and (2) it would take almost 20 years for the initial disequilibrium to work itself out, assuming no other changes take place.

A negative coefficient of adjustment was obtained for both the demand and supply equations in the operator labor market, implying that there will be movement away from equilibrium if no changes take place in the economic variables. Such a conclusion would indicate considerable instability in the operator labor market. One possible reason for this theoretically inconsistent result is that the distributed lag model specified for the operator labor market is not correct. The model used assumes that the movement towards equilibrium follows an asymptotic path with the largest proportion of disequilibrium removed in the first period. An alternative approach may be to assume that the movement towards equilibrium follows a logarithmic normal distribution with the maximum effect occurring some time after the disequilibrating change takes place [13]. To pursue this and other approaches would be a study in itself.

The estimated elasticities of adjustment present an interesting pattern among the components of the agricultural labor force. For the purpose of this analysis, the assumption is made that the coefficient of adjustment for both the demand and supply of operator labor is zero, since the coefficient of the lagged dependent variable was not significantly different from one. On the demand side, the coefficient of adjustment is largest for the hired labor market, about one-fourth as large in the unpaid family labor market, and essentially zero in the operator labor market. This is consistent with the hypothesis that the hired labor component is the marginal labor input in the production process and, hence, is the one that farmers manipulate most readily. Also, it is the only farm labor input that receives a direct payment. In a sense, unpaid family labor is also a marginal component, but since it is directly attached to the farm and receives no fixed payment, it appears that the farmer does not respond in his use of this component to changes in economic stimuli as rapidly as for hired labor.

As a demander of his own labor, he will be least responsive to factors that would influence the use of his own labor.

On the supply side, the coefficients of adjustment are approximately equal for hired and unpaid family labor. This similarity, in part, suggests that these two components have similar alternative opportunities. It is also to be noted that they have similar demographic characteristics, such as age and education; that is, both components consist of a large proportion of young people of school age. Since one alternative open to them is to drop out of the labor force entirely, they are quite responsive to economic stimuli in offering their labor services. Operator labor, on the other hand, is older, has fewer alternative opportunities and a much stronger commitment to agriculture; consequently, the supply is much less responsive to economic stimuli.[18]

Short-run demand elasticities with respect to farm wage rates ranged from −.069 for operator labor to −.681 for unpaid family labor. This means that a ten percent increase in farm wage rates would result in a .7 percent decrease in the quantity of operator labor demanded and a 6.8 percent decrease in the quantity of unpaid family labor demanded, other things being equal. Short-run supply elasticities with respect to farm wage rates range from .005 for operator labor to .681 for unpaid family labor. The ranking is the same for both demand and supply elasticities. Based on the composition of the agricultural labor force, the most important component (operator labor) has the lowest elasticities, while the least important component (unpaid family labor) has the highest elasticities.

The long-run supply elasticities with respect to farm wage rates for both hired and unpaid family labor are equal to approximately 1.5, which is to be expected since hired and unpaid family labor are similar in demographic characteristics. The long-run demand elasticities are very diverse —about −.5 for hired labor and −3.0 for unpaid family labor.

With respect to nonfarm income, the supply elasticities are again about the same for unpaid family and hired labor, both in the long-run and the short-run; but for operator labor the short-run supply elasticity is considerably less. This again supports the conjecture that hired and unpaid family labor have approximately the same alternatives, whereas operator labor has a stronger commitment to agriculture and hence is not as responsive to changes in nonfarm income.

The elasticities of the substitution variables present an interesting pattern. In the short-run, hired labor appears to be a perfect substitute in the demand for unpaid family labor (elasticity is −1.063). In the demand for operator labor, however, hired labor is still a substitute, but the substitution is not perfect (elasticity is −.202). Operator labor tends to substitute in the demand for hired labor (elasticity is −.115), but the relationship is weak—the coefficient is not statistically significant, although it is larger than the standard error. These results add further support to the hypothesis that the components of the agricultural labor force are interchangeable in the production process, particularly hired labor for unpaid family labor.

---

[18] This result is consistent with Clawson's findings [2] that the bulk of the change in the operator labor force has not come about by a shifting of the operators, but rather by a decline in the rate of entry into farming.

On the supply side, the short-run elasticities of the substitution variable are also quite informative. The magnitude of the elasticities provides a further indication of substitutability among the components. For example, the elasticity of the quantity of hired labor in the supply of unpaid family labor equation is −.645, implying that a 10 percent change in the quantity of hired labor would be accompanied by a 6 percent change in the opposite direction in the quantity of unpaid family labor supplied, *ceteris paribus*. Part of this change in the quantity of hired labor may be caused by a shift of workers from the unpaid family labor component to the hired labor component, or vice versa.

The long-run elasticities provide additional evidence of substitutability among the components of the farm labor force, particularly hired labor for unpaid family labor, adding support to the conjecture that unpaid family labor moves into the hired labor component or out of agriculture in the longer run. Even in the long-run, the substitution variables have elasticities that are less than −1 in absolute terms, implying that unpaid family labor does not substitute perfectly for hired labor and that operator labor is not a perfect substitute for hired labor in the production process.

Policy Implications

Government policies designed to solve some of the income problems in agriculture may now be evaluated on the basis of the results of this study. The discussion will center around the price support program vs. monetary and fiscal policy, a minimum wage law in agriculture, and efforts to improve the labor transfer process.

Given the inelastic nature of the supply and demand curves in the short run, any economic force that shifts either curve, even slightly, will have a significant impact on the wage rate but a relatively smaller impact on the quantity of labor used. In the long run, when relationships are more elastic, the major impact of changing economic forces would be on the quantity of labor used rather than on wages. Consequently, in the short run, the impact of farm price support programs would be to shift the demand curves for labor to the right,[19] resulting in a higher wage rate but not much additional employment. The impact of monetary and fiscal policies that serve to raise the level of nonfarm income and lower the level of unemployment (both are included in X_{10}) would have the effect of shifting the supply curve of labor to the left, thus giving a higher wage rate for a smaller number of people employed in agriculture. In the longer run, the price support program would tend to raise wage rates only slightly but would lead to a higher level of agricultural employment, whereas monetary and fiscal policy would raise wage rates relatively more but would lead to a lower level of agricultural employment, *ceteris paribus*.

---

[19] Farm support programs that lead to higher farm prices result in an increase in the demand for labor, other things being equal.

If there were an oversupply of labor in agriculture, the price support program would tend to aggravate the labor adjustment problem, particularly in the long run. However, increases in nonfarm income, in the long run, would result in a sizable shift of labor out of agriculture and a higher wage rate for those that remain. Given a goal of higher incomes in agriculture, such a situation would be desirable.

The minimum wage law in agriculture can also be analyzed with the aid of this study. If the farm wage rate were raised above its equilibrium level, the impact would be similar to that of the price support program for agricultural products. The higher wage rates would decrease the quantity of labor demanded and increase the quantity of labor supplied, thus making the problem of underemployment and labor adjustment in agriculture even more serious. To the extent that the farm wage rate is a reasonably good proxy measure of the price of unpaid family and operator labor, the impact of the minimum wage law would be greatest on the unpaid family labor component, which has the highest short- and long-run elasticities, and smallest on the operator labor component, which has the most inelastic relationships.[20]

The fact that people lag in response to economic stimuli also has policy implications. Differences in the speed of response may have an important bearing on the outcome of a particular change or policy variable. For example, this study shows that farmers respond much more rapidly to economic stimuli affecting the demand for hired labor than to those affecting the demand for unpaid family labor, even though the elasticities of demand are greater for unpaid family labor. Policy measures should recognize these differential responses, both as a means of obtaining more efficient results from given policy measures and in terms of their implications for the goals of policy measures.

The Contribution of Foreign Assistance to Agricultural Development*

WAYNE SCHUTJER AND DALE WEIGEL

In recent years, national and international aid agencies have allocated a considerable amount of resources to the agricultural sector of less developed countries. The purpose of the research reported in this article is to determine whether these resources have made an identifiable contribution to the recipients' agricultural production. To answer this question, a cross sectional sample of 13 major aid receiving countries was investigated. Changes in agricultural production between two three-year periods (1960–1962 and 1964–66) were statistically related to the increase in land area cultivated, the increase in labor employed, and agricultural aid per hectare. The form of the statistical relationship was derived from a Cobb-Douglas production function. Aid to agriculture was subdivided into three categories: (a) aid in financing agricultural inputs, such as fertilizer; (b) technical assistance; and (c) aid to finance facilities to produce agricultural inputs (e.g., fertilizer plants). The analysis showed that there was a statistically significant relationship between aid-financed inputs and agricultural output. This type of aid explained nearly one-third of the average 15 percent increase in agricultural output experienced by the 13 countries. On the other hand, there were no statistically significant relationships between the other two types of aid and agricultural production; but this is not surprising, considering the short period of time investigated.

THERE can be little doubt that agricultural development is one of the major tasks facing the less developed nations. The dimensions of the world food problem have been described vividly by the President's Science Advisory Committee [6]. More generally, it has been argued effectively that agricultural development is a necessary prerequisite to general economic development [2, 3].

Recognizing the importance of agricultural progress, the United States and other advanced nations have channeled a major portion of their foreign development assistance into agricultural development and food aid programs [1, p. 23]. Little quantitative analysis, however, is available regarding the effectiveness of foreign assistance to agricultural development, and that which is available is directed primarily toward an evaluation of food aid and related programs [7, 10].

The purpose of this paper is to report on research designed to measure the impact of foreign economic assistance on agricultural output in the less developed nations. Attention is focused on the 13 less developed

countries that were major recipients of United States foreign aid during 1962–1965. However, the foreign assistance flows considered include not only the agricultural assistance given by the United States Agency for International Development but that of the International Bank for Reconstruction and Development, the International Development Association, and the Inter-American Development Bank as well.[1]

Foreign Assistance to Agriculture

Foreign aid to agricultural development can take several forms: (1) foreign exchange for the importation of agricultural inputs, (2) capital development projects, (3) local currency allocations to the agricultural sector, and (4) technical assistance activities.[2]

For purposes of this study, we were interested in segregating aid flows that can be expected to yield output increases in the short run from those that are directed at improving the social and economic infrastructure in the agricultural sector and thereby can be expected to yield longer term results. Consequently, capital project assistance, such as that directed toward providing credit, was segregated from assistance to projects with a longer maturity. The resulting categories are:

Type I—High Impact Assistance: Agricultural assistance directed toward short-run increases in output. Included are foreign exchange for the importation of agricultural inputs (e.g., fertilizer and seed), local currency allocations to agriculture, and capital development projects such as credit, mechanization, and land preparation.

Type II—Long-Term Capital Development Assistance: Assistance to finance projects with long-term yields. Included are capital development projects designed to improve the agricultural infrastructure, irrigation projects, and projects designed to increase domestic production of agricultural inputs such as fertilizer.

Type III—Technical Assistance: Foreign assistance designed to help build the basic institutions and develop the human skills required for sustained economic, social, and political development.[3]

Data on each type of foreign assistance flow for each nation are presented in Table 1. The assistance flows shown represent only funds actually received and expended during 1962–1965; thus, to some extent, they also reflect commitments and authorization of previous years.

---

[1] The foreign agricultural assistance of other donor nations, not channeled through these international organizations, is excluded because of a lack of comparable expenditure data. However, this omission does not appear serious in the major U.S. aid recipient nations studied.

[2] P.L. 480 food shipments are not considered to be aid to agricultural development; only those local currency balances actually expended for agricultural development projects are treated as agricultural assistance in this paper.

[3] This concept of technical assistance is the same as that of A.I.D. [1, p. 250].

Table 1. Agriculture assistance expenditures, 1962–1965

Nation	Type of assistance			
	I	II	III	Total
	thousand U. S. dollars			
Brazil	45,845	150	16,970	62,965
Chile	21,284	2,997	1,480	25,761

On the average, each nation received nearly 73 million dollars in foreign agricultural assistance during 1962–1965, of which more than two-thirds was Type I aid. The proportions vary, however, as Korea received an agricultural assistance package composed of over 90 percent Type I assistance, while both the Philippines and Thailand received less than one-third of their agricultural assistance in that form.

Procedure

The value of agricultural output during 1960–1966 was computed from data provided by the Regional Analysis Division of the United States Department of Agriculture.[4] Computations were those for which comparable land area and production data were available for those years. In general, neither tree crops, such as coffee and olives, nor livestock products were included. The proportion of total agricultural output included varies, depending upon the weight of excluded crops, such as coffee, in the total value of agricultural output. Land area data comparable with the output data and employment in agriculture (economically active population) were also collected for the 13 nations [3, 4, 5].

---

[4] In computing the value of crops included in the value of output production, the U.S.D.A. uses 1957–1959 average prices at the farm level; to the extent possible, commodities are combined on a calendar year basis. Most of the basic output data are available in [11, 12, 13, 14].

A Cobb-Douglas production function was assumed as the form of the basic relationship between output, land, labor, and agricultural investment, both domestic and foreign. Quantitative estimates of the impact of foreign assistance flows on agricultural output in the 13 nations were obtained by using a multiple regression model of the form

$$Y_i = b_0 + \sum_{j=1}^{5} b_j X_{ji}$$

where: Y = the percentage increase in the value of crop production between the periods 1960–1962 and 1964–1966. Constant 1957–1959 prices were used.[5]

X_1 = the percentage increase in land area employed in crop production between the periods 1960–1962 and 1964–1966.

X_2 = the percentage increase in the number of economically active people in agriculture between 1961 and 1965.[6]

X_3 = high impact foreign assistance per hectare of cropland during the period 1962–1965 (Type I aid).

X_4 = long-term capital development assistance per hectare of cropland during the period 1962-1965 (Type II aid).

X_5 = technical assistance per hectare during the period 1962–1965 (Type III aid).

Lack of information about domestic agricultural investment (both public and private) and about agricultural capital stock required the assumption that domestic net investment in crop production was allocated between that associated with changes in land area and that associated with foreign assistance flows.[7] Thus, in the model, one part of net domestic investment in crop production is assumed to be proportional to changes in land area devoted to crop production, and the remaining net domestic investment in agriculture is assumed to be related to foreign assistance flow. As a result, the regression coefficients associated with the aid variables must be interpreted as reflecting the impact of foreign assistance and related net domestic investment.[8] This interpretation is consistent with the philosophy of "self-help" underlying the foreign assistance program in that foreign assistance is utilized to redirect priorities and stimulate host country activities in priority areas [1, pp. 2–3].

---

[5] For India and Pakistan, 1966 data were not utilized because of the serious drought these nations experienced in that year.

[6] Economically active is defined to include all persons engaged in an economic activity, whether as employees, own-account workers, salaried employees, or unpaid workers assisting in the operation of a family team. Comparable data were not available for each nation for the entire period 1961–1965. Thus, in some instances, it was necessary to extrapolate from the data available to obtain an estimate for a given year.

[7] This approach neglects what Phillip Raup has termed accretionary capital formation. However, by definition, accretionary capital formation is a long term phenomenon and hence is not significant over a four-year period [11].

This study does not take into account the impact of foreign assistance on goals other than total output. It is important to note, however, that social goals such as income distribution and popular participation in decision making may also be sought through foreign assistance programs. Since these contributions of foreign assistance have not been included, the results will understate the total contributions of aid.

The Impact of Foreign Agricultural Assistance

The regression equation was estimated in three forms:

$$(1)\ Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3$$
$$(2)\ Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4$$
$$(3)\ Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_5X_5$$

The regression coefficients for the aid variables are provided in Table 2. The coefficients associated with land and labor were not significant at the .05 level; however, at the .10 level, land was significant in equations 1 and 3.

The negative coefficients of the Type II and Type III aid variables are not unexpected. Neither capital projects nor technical assistance can be expected to yield significant output results over a four-year period. Moreover, current output may be reduced as domestic investment is diverted to help finance the long-term capital and technical assistance projects.

The Rate of Return on Type I Assistance

Agricultural production in the 13 countries increased by an average of 15 percent between 1960–1962 and 1964–1966; that is, from $113 to $130 per hectare. During the same period, the average Type I agricultural assistance was $8.80 per hectare. From equation 1 of Table 2 we see that, on the average, each dollar of Type I assistance was associated with a .54 percent increase in output per hectare. Thus, on the average, Type I assistance and related capital formation contributed to a 4.75 percent increase in output (8.80 × .54 percent) or nearly one-third of the total increase of 15 percent.[9]

In calculating the rate of return of each dollar of Type I agricultural

---

[8] See Appendix A for the derivation of the statistical model from the Cobb-Douglas production function.

[9] In more specific terms, the elasticity of Y with respect to Type I assistance is 4.75 at the mean values.

Table 2. Estimates of regression coefficients for the aid variables

Equation form	R^2	F	Aid variable coefficients		
			I	II	III
(1) $Y = b_0 + \sum_{1}^{3} b_i X_i$	.55	3.67*	.536* (.198)		
(2) $Y = b_0 + \sum_{1}^{4} b_i X_i$	.62	3.32*	.624* (.205)	−.874 (.700)	
(3) $Y = b_0 + \sum_{1}^{3} b_i X_i + b_5 X_5$	.66	3.81*	.549* (.184)		−3.22 (2.06)

* Significant at the .05 level.

assistance, we must calculate the accumulated increase in output associated with the aid flow over 1961–1965. Thus, we know that average output per hectare in 1965 (0_4) was $5.37 larger than in 1961 (0_0) or $.61 for each dollar of Type I assistance made available during the period:

$$\phi = 0_4 - 0_0 = (0_1 - 0_0) + (0_2 - 0_1) + (0_3 - 0_2) + (0_4 - 0_3)$$

The cumulative increase in output (0^*) over 1961–1965 is calculated as follows:

$$0^* = (0_1 - 0_0) + (0_2 - 0_0) + (0_3 - 0_0) + (0_4 - 0_0)$$

If we assume that the aid flow and the increase in output occurred evenly over the four-year period, 0^* would equal $13.42 and the rate of return on $8.80 of Type I assistance would exceed 52 percent. Other assumptions are, of course, possible; for example, in the most pessimistic case, the total increase in output occurs only in 1965. Thus $0^* = \Phi$, and the total increase in output over the four-year period would be only $5.37 on an investment of $8.80. The rate of return would be negative in this case.

Conclusions and Implications

The major conclusion of the study is that high impact (Type I) foreign assistance to the agricultural sectors of the 13 nations studied was associated with substantial increases in agricultural output. The lack of domestic investment data restricts the usefulness of a rate of return calculation, which should include consideration of the domestic investment associated with Type I assistance. However, Type I foreign assistance is primarily directed at current bottlenecks in the agricultural economy, and it is likely that fewer domestic resources would have been directed to agriculture in the absence of foreign aid, while those that were would have been used less efficiently. Thus, a large portion of the additional output is properly attributed to the aid.

The lack of association found between output and both technical assistance and long-term capital flows reflects a series of factors. Type I assistance in the form of credit and agricultural requisites, including fertilizer and pesticides, has a quicker pay-off than technical assistance and capital projects. Thus, an analysis that considers only a four-year period will no doubt overlook output increases derived from aid activities with a longer maturity. In addition, the analysis does not consider technical and long-term capital assistance provided during the years preceding 1961, both of which may account partially for the impact of Type I assistance on current output levels.

Perhaps equally important, foreign assistance to the agricultural sector is not always directed at output goals. Social goals, such as income distribution and popular participation in decision making, also may be sought. Therefore, the use of output as the only indicator of aid effectiveness presents a somewhat biased result. This is especially true in view of the fact that technical assistance is the aid instrument most often used to attain non-economic agricultural sector goals.

A more pessimistic view, however, suggests that technical assistance and long-term capital projects are initiated in non-priority nations, or nations having limited output potential given current agricultural policies and programs. Even though each nation included in this study is a major aid recipient, the possibility still exists that technical assistance and long-term capital projects in agriculture may have been directed to those nations that had not formulated and implemented effective overall programs for agricultural development. Technical assistance and certain capital projects may have been made available to those countries in order to "maintain a presence" in agriculture until effective agricultural programs could be implemented.

These conflicting interpretations of the results of our analysis make it abundantly clear that its relatively simple approach cannot provide a complete explanation of the effects of foreign assistance on agricultural development.[10] More research is required to extend the time period of the analysis and to incorporate other factors that may explain changes in agricultural production. It is particularly necessary in this connection to investigate the quantity of domestic inputs into agriculture that are associated with aid. Furthermore, it would be useful to determine whether the response of domestic inputs is related to objective factors such as the type of aid, the recipient country's level of economic development, and the type of political organization. If such a relationship exists, it would be possible to design "optimal" aid programs for each country.

---

[10] Thus, the R^2's in Table 2 are not as high as would be desired. On the other hand, they are statistically significant.

The type of research that is needed requires extensive data, which can be generated only by detailed case studies. Primary data collection is specifically required to determine the quantities of domestic inputs into agriculture. The secondary sources employed in this paper simply do not contain the necessary information.

Despite these data limitations and the short time span investigated, some conclusions for foreign assistance programming can be drawn. Specifically, it has been shown that aid to finance fertilizer and other agricultural inputs can be expected to yield a rather large return, and this return must be considered to be the opportunity cost of resources devoted to longer term agricultural projects. Even when this opportunity cost is considered, however, the results of this study do not imply that there should be a reallocation of agricultural aid. Surely we must continue to encourage long-term agricultural investments that are designed to increase the social and physical capacity of the less developed nations to absorb and generate resources represented by fertilizer and improved varieties. But we must recognize that there appears to be considerable scope for increased agricultural output based upon the provision of these new inputs within the existing institutional and economic framework of the less developed countries.

Appendix A

This Appendix provides a theoretical rational for the preceding statistical analysis. Following are the variables and assumptions required by the statistical analysis.

The variables:

O—agricultural output
L—land employed in agricultural production
M—labor employed in agriculture
C—the agricultural capital stock

Agricultural output is a function of the inputs:

$$O_i = f_i(L_i, M_i, C_i). \tag{1}$$

The subscripts indicate reference to country (i).

Equation (1) is completely general in the sense that every country could have a completely different production function. While it may be realistic to make such an assumption, it is impossible to estimate the parameters of various functions from cross-sectional data. Since we are constrained by data limitations to a cross-sectional analysis, we must make the simplifying assumption that the production function is the same for every country. The general form of the production function is:

$$O_i = f(L_i, M_i, C_i). \tag{2}$$

Assume that the function in (2) has the form of a Cobb-Douglas production function.

$$O_i = AL_i^aM_i^bC_i^c. \tag{3}$$

This function can be expressed in terms of changes in inputs and outputs by taking logarithms of both sides and then taking the total derivative.

$$\frac{dO_i}{O_{oi}} = \frac{dA}{A} + a\frac{dL_i}{L_{oi}} + b\frac{dM_i}{M_{oi}} + c\frac{I_i}{C_{oi}}, \tag{4}$$

where I_i is the change in capital stock.

Net investment in agriculture (I_i) may be divided into three components: (a) that associated with aid, (b) that associated with changes in land area under cultivation, and (c) an autonomous component.

$$I_i = B_i + l_i dL_i + m_i I_{ia} \tag{5}$$

where I_{ia} is the aid invested in country i's agricultural sector.

In deriving the function to be statistically estimated, we have made the following assumptions about the parameters in equation (5):

$B_i = 0$; that is there is no autonomous component of domestic investment. Domestic investment is associated either with changes in land under cultivation or with aid.

l_i is proportional to the initial capital stock on the land. That is, $l_i = p_i k_i$, where k_i is the capital stock per initial unit of land; $k_i = C_{oi}/L_{oi}$

The parameter p_i is the same in every country, $p_i = p$. With these assumptions, substituting (5) into (4) and k_iL_{oi} for C_{oi}, we have

$$\begin{aligned} \frac{dO_i}{O_{oi}} &= \frac{dA}{A} + a\frac{dL_i}{L_{oi}} + b\frac{dM_i}{M_{oi}} + c\frac{[pk_i dL_i + m_i I_{ia}]}{k_i L_{oi}} \\ &= \frac{dA}{A} + (a + pc)\frac{dL_i}{L_{oi}} + b\frac{dM_i}{M_{oi}} + c\frac{m_i}{k_i}\left(\frac{I_{ia}}{L_{oi}}\right). \end{aligned}$$

The parameters in equation (6) may be estimated statistically if it can be assumed that the ratio m_i/k_i is the same in every country. Such an assumption would require that m, the constant of proportionality between net investment and aid, be higher in countries that have a larger initial stock of capital per unit of land (k). The assumption does not require that both m and k be the same in all countries. Since the factor of proportionality between aid and net investment (m) is an indication of self-help, the assumption requires that self-help be greater in countries with a larger capital stock per unit of land.

With the necessary assumptions, equation (6) shows that the percentage change in agricultural output will be related to the percentage change in land area under cultivation, the percentage change in labor employed in agriculture, and the amount of foreign aid per unit of land initially under cultivation. In the statistical regression equation, the constant term represents the autonomous change in agricultural production not represented by changes in factor inputs. The coefficient of the percentage change in land area is the sum of the elasticity of output with respect to changes in land and the product of the elasticity of output with respect to capital and the factor of proportionality between changes in land area and net investment. The coefficient of the percentage change in labor inputs is the elasticity of output with respect to labor. Finally, the coefficient of the aid per hectare variable is the product of the elasticity of output with respect to capital inputs and the ratio of (a) the constant of proportionality between net investment and aid and (b) the initial capital stock per unit of land. This coefficient thus measures the response of output to additional capital inputs and the relationship of total investment to aid.

Theories Explaining the Persistence of Low Resource Returns in a Growing Farm Economy*

LUTHER G. TWEETEN

Low rates of return (defined as earnings below opportunity costs) on farm resources have long been considered a major farm problem and one justification for government commodity programs. This paper first analyzes influences (such as economic growth, inflation, and technology) that generate disequilibrium and low returns. But the major issue analyzed is why farm disequilibrium persists after an extended period of full national employment, a strong national economy, an expansion of the aggregate farm plant, and a slow growth of farm productivity in the 1960's. The fixed resource theory, the increasing returns to size theory, and the imperfect competition theory are examined to explain persistence and permanency of disequilibrium and low returns. The fixed resource theory explains low returns as a labor fixity problem and suggests that the problem is either nonexistent or temporary. The increasing returns to size theory points to an extended duration for the low returns problem as long as the large majority of farms continue to operate on uneconomic size units. Finally, the imperfect competition theory depicts low returns as virtually permanent, given the economic structures of the farm and nonfarm sectors.

LOW rates of return (defined as earnings below opportunity costs) on farm resources, long considered a major farm problem, have been explained mainly by technological change and asset fixity. The aggregate productivity index for farms was the same magnitude in 1966 as in 1961 and only 4 percent greater in 1968 than in 1960 [24, p. 16]. The farm economy was expanding—the volume of production inputs increased 11 percent from 1960 to 1968. Despite slowing of productivity growth, a strong national economy that has grown steadily for eight years, comparatively low rates of national unemployment, and expansion of the aggregate farm plant, the farm economy continues to be depressed as measured by low returns on resources [21, 25]. Depressed returns persist despite considerable time to overcome asset fixity and shifting of supply (the shift measured by productivity) to the right at a slower rate than demand.[1]

---

* The author is indebted to Leroy Quance, Vernon Eidman, and at least six anonymous reviewers for numerous helpful comments.

[1] The supply curve can shift from changes in input prices as well as from changes in productivity. Since input prices have risen sharply, ceteris paribus, this has shifted the supply curve to the left, and strengthens my argument that supply has shifted less rapidly than demand to the right. Some might also argue that the change in the productivity index reflects a movement along the supply curve (or production function) rather than a shift in the supply curve. Such an association should show up in a correlation between changes in the parity price ratio and changes in the productivity index. I have been unable to detect statistically any such association from empirical data.

LUTHER G. TWEETEN *is professor of agricultural economics, Oklahoma State University.*

young and very old workers who tend to have low earnings and fewer opportunities for outside employment contributes to a low opportunity price at which to salvage farm labor. The median age of farmer operators was approximately 51 years in 1960, when 5.3 percent of the total farm labor force were between 14 and 17 years of age and 14.7 percent were age 60 and over. For the same age groups in urban employment, the respective percentages were 3.0 for younger group and 9.7 for the older group.

Analyses show that the farming industry receives a low return on resources when all farm resources are valued at their opportunity price [15, 21, 25]. It was found that gross farm income failed to cover all costs of farming when farm resources were valued at their opportunity price, that is, what they would likely earn if employed elsewhere.[4] The problem of low returns on farm resources appears to be real. We must look beyond the opportunity price to explain the difference between actual returns and the acquisition price of farm resources.

The transfer cost hypothesis

Wage rates in economic equilibrium differ because of transfer costs. The wage rate in agriculture must drop below the opportunity value less transfer cost to justify economically the transfer of labor from agriculture. The opportunity price P_O less transfer cost is designated P_T in Figure 1. Transfer costs are unlikely to be a large part of potential earnings in the nonfarm sector. If moving costs are $500 and the migrant will earn $5,000 for 20 years in new employment, moving costs are only .5 percent of future earnings. Thus, monetary transfer costs appear to be too small to explain the discrepancy between the earnings of comparable farm and nonfarm resources. Transfer costs may loom large, however, for individuals who, because of old age, have few years of productive employment ahead, who must search long and perhaps unrewardingly for a new job, or who have little capital or credit base on which to support the transition.

---

[4] The USDA study [25] compared "net farm income from farming and the amount of income or returns that comparable resources would earn in other employment. This comparison indicates whether or not farmers' resources are earning as much in farming as they could be expected to earn in the nonfarm economy" [25, p. 33].

Farm resources such as fertilizer, protein feeds, and pesticides that were not in excess supply were valued at acquisition price. Farm land was valued in several alternative rates, one of which assumed that the farmer would sell his farm and invest the amount received in common stocks, on which he would receive dividends and capital gains. Labor was valued at the urban wage rate adjusted downward for the age, schooling, and sex ratio of farm workers vis-a-vis urban wage earners. The assumption is that at the margin farmers can sell their specialized capital equipment to other farmers but salvage their excess labor and financial equity in the non-farm sector.

The endodermal hypothesis

The price that induces outmovement of labor from agriculture may be considerably lower than P_T for workers who value highly the farm way of life. Brewster labeled this the "endodermal" hypothesis explaining the farm problem [2, pp. 129ff]. If alternate employment means leaving the community, the farmer may accept a low return for his labor rather than leave relatives and friends. The reservation price of farm labor is labeled P_R. It is the price below which the farm labor earnings must fall before alternative employment will induce release of labor from agriculture, given potential earnings in nonfarm employment, transfer cost, psychic satisfaction from farming, and expectations of future farm earnings and of living in the city.

Given favorable economic conditions such as immediately followed World War II and indicated by MVP_1, farm employment X, and labor earnings P_A, suppose that prices received by farmers fall because supply is increasing faster than demand. This can occur because government supports are curtailed, because of favorable weather for crops, or because demand contracts due to a depressed national economy or declining farm exports. If farm labor responded strictly to opportunity costs in the absence of transfer costs and special values on farm employment, then outmovement of farm labor would begin with the drop of the marginal value product just below MVP_2 (Figure 1). Reduction of farm employment would begin with a drop in the marginal value product to just below MVP_3 if transfer costs are included. And the marginal value product would need to fall below MVP_4 to induce lower farm employment when the psychic satisfactions of the farm way of life, imperfect knowledge, and other factors reflected in P_R are considered. The marginal value product could range from MVP_1 to MVP_4 without changes in farm employment. The farm economy would be in equilibrium" in a period requiring fewer resources only if all farm labor were valued at its reservation price, P_R. Use of any other price, P_A, P_O, or P_T, would show that the gross income in agriculture would not cover all farm costs.

Effects of resource fixity on farm output and earnings

Before appraising the actual role of fixed resource theory in explaining persistence of low returns, it is necessary to examine the fixity of farm production resources in addition to labor. How fixed are farm resources? To answer this question, it is useful to divide farm resources into five categories: (a) financial resources, (b) operating capital, (c) durable capital, (d) real estate, and (e) labor. It is also necessary to consider two basic dimensions of fixity—durability of resources and the relationship of the marginal value product to the four prices listed in Figure 1.

Financial resources such as currency, bank deposits, and bonds are quite readily transferable to nonfarm investments and should cause no extended problems of fixity and attendant low returns.

Operating capital such as fertilizer, fuels, seed, repairs, pesticides, and hardware supplies have generally low opportunity prices for salvage, once committed to farming. These supplies, purchased on the basis of an expected product price, are likely to be used even if the product price falls sharply during the production period. But the inputs are consumed quickly, most in one production period. Hence the farmer can correct his error by purchasing fewer operating capital inputs in the next production period. Furthermore, the farm MVP's for these inputs have tended to lie above acquisition prices. It follows that operating capital poses no real problem of input fixity.

Durable capital items, such as farm machinery, give off services over an extended period and have low salvage value outside of the farming industry. USDA estimates [22, p. 57] show an annual depreciation rate for farm machinery of 10 percent, although the services given off fall less than 10 percent per year from a given stock. Even if services decline at half this rate, without adding to the stock of machinery the machinery input would fall nearly one-fifth in four years—hardly a serious degree of fixity. Again, data conflict on where the marginal value product of machinery lies in relation to acquisition price. The Tyner-Tweeten study indicates machinery is not in excess supply [18]. Farm produced durables, such as breeding stock, would seem not to create serious problems of fixity because the acquisition price varies proportionately with farm economic conditions and because they can be salvaged at slaughter prices.

The fourth input category, farm real estate, is durable and has a low opportunity price for salvage in nonfarm uses (except around cities). Its degree of fixity is so great, however, that its price is determined by economic conditions within agriculture. Since land price does not determine farm output, it would be unwise to blame excess capacity and associated low returns in farming on the land price. It will become more apparent later in this report that low returns on farm land arise because farmers pay "too much" for land.

Thus, because the input life is short, or because the MVP exceeds the acquisition price, or because of the pricing structure, the non-labor resources (accounting for about three-fourths of all farm inputs) do not support the asset fixity theory as an explanation of low farm returns over an extended period.

We must return to labor as the "problem" resource, if fixed resource theory is to provide an explanation of low farm resource returns. Labor is a durable resource; unlike other resources, it increases in supply—thanks to high birth rates—even though farmers do not purchase more from the nonfarm sector. Because a change in the labor input itself has little effect on farm output, it would appear that resource fixity would not explain excess capacity in agriculture. Labor is more important than its contribution to output might suggest, nevertheless, because capital inputs are often used in fixed proportions to labor on family farms and because labor is very important as a *denominator* in expressing returns per *unit* of labor.

In short, there are indications, cited earlier, that farm labor is in excess supply and that its marginal value product lies below not only its acquisition price but also its opportunity price less transfer cost P_T. This suggests that many farmers could increase their earnings by employing their labor resource elsewhere. Questions remain of whether earnings below P_T represent inefficiency and a cost to individuals and society and whether, in fact, the disequilibrium ascribed to fixity of labor even exists.

Whether earnings below P_T represent economic disequilibrium depends on the source of the gap. Given no disassociation of private and social costs (or returns), earnings of labor below P_T would indicate economic inefficiency, and the product of society could be raised by closing the gap. If the gap arises because of reasonable inertia in making adjustments to dynamic forces that constantly generate disequilibrium and the inertia can be overcome only with great trauma to workers, the gap may not represent a social cost. If the gap arises only because farmers, though fully informed of alternatives, place a high value on farming as a way of life, then the gap measured by usual economic yardsticks does not represent a social cost. If the gap arises only because farmers are uninformed of employment opportunities elsewhere or of the city way of life, it is then a social cost as well as a private cost unless the cost of providing such knowledge is prohibitive. And if the gap arises because of discrimination and labor unions that inhibit mobility, it may represent a private and social cost but no disequilibrium; that is, farm workers may not close the earnings gap because they cannot obtain the higher paying nonfarm jobs they are able to perform.

The flip-flop antithesis—the problem of high returns

I concluded that fixed resource theory explains the secular problem of low returns only through the labor resource, but even this last beachhead of alleged fixity is severely threatened. The challenge to the fixity of farm labor is raised by several findings: (a) that farm operator and hired laborer earnings are consistent with the schooling-earnings relationship over several occupations [16, p. 15]; (b) that rates of adjustment to equilibrium for farm labor and other resources are comparatively rapid [19]; and most important, (c) that farmers, according to the Hathaway-Perkins study [5], engage in considerable experimentation—a considerable number actually try nonfarm jobs, but 9 persons return to farming for each 10 who leave, presumably because it is the "best" alternative for use of resources.

The tentative conclusion is that there is no problem of low resource returns in farming, with factor markets operating efficiently to hold farm labor earnings to opportunity cost levels. Of course, there is dynamic resource disequilibrium, which is alleviated quickly enough by outmigration to keep farm earnings nearly on a par with nonfarm earnings. If farm resource earnings appear low, it is only because economists have imputed to farm labor too high an opportunity cost. And what was considered to be the major economic problem of commercial farms, low resource returns, evaporates—its only 'reality" an illusion created by economists. Fixed resource theory, then, helps to explain the lack of annual variation in farm input in the face of fluctuating prices but does not explain the "nonexistent" secular low returns on farm resources.

Acceptance of the antithesis places farm problems in an entirely new perspective. The problem becomes one of low absolute returns rather than low relative returns on farm labor. Raising the opportunity price of farm labor through education and training takes even greater priority. The problem of disequilibrium remains, but it is the high return on schooling investment (much of it financed from nonfarm sources) rather than the low return on farm production resources that becomes the singular focus of attention. Shortage of schooling, rather than excess of production resources, gains prominence. The new interpretation, emphasizing shortage and high returns rather than excess and low relative returns, is indeed a flip-flop.

Nevertheless, additional strong evidence contradicts the conclusion that resource markets are efficient. That ". . . back-movement into agriculture offsets 90 percent of the mobility out of the industry" [5, p. 351] reflects a serious lack of job information indeed and indicates that factor markets must be working very inefficiently. Only a small proportion of farm workers move to a nonfarm job each year, and there is no reason to suppose that even these are efficient in locating the best jobs available to them.

In addition, support for the proposition that much redundant labor remains in agriculture can be found from numerous sources in addition to those cited earlier. Ninety percent of all farm output is produced on farms that account for half of farm labor man-hour requirements. Since about 7 percent of farm production capacity is excess [17, 18], release of farm labor from units that produce one-tenth of farm output would cause no food and fiber shortage.[5] If this half of all farm labor has a marginal product greater than zero in the nonfarm sector, it could contribute more to society there. The conclusion that about half of farm labor is redundant is consistent with the production function results presented earlier. It is also supported by microeconomic results aggregated to area levels [27]. Finally, doubts have been raised about the validity for mobility studies of the Social Security data on which the "efficient-labor market" contention rests heavily [1].

---

[5] In fact, output could expand as better managers would take over the smaller farms. In all likelihood, the marginal product of the above farm workers is negative, allowing for reorganization of farms.

I reject the flip-flop antithesis as premature. This should not be interpreted as belittling the massive and monumental accomplishment of factor markets—nearly 40 million net migrants have left farming since 1929! What is at issue is whether considerable redundant labor still remains in farming and whether factor markets need to be improved. My answer to both questions is "yes". It is not within the scope of this paper to list needed improvements in factor markets, but greater investment in education is certainly complementary with such improvements.

The thesis and antithesis can partially be reconciled. The farm labor market works most efficiently for the young, and outmigration of this group has enabled agriculture to dissipate much of the dynamic disequilibrium generated each year by output-increasing technology, inflation, and other factors. For the reasons discussed, operator labor and associated family labor do not so readily adjust out of agriculture, and it is this group that constitutes a sizable reservoir of surplus labor that in so many cases could be employed more profitably elsewhere.

The problem of surplus farm labor will diminish in the future, and the flip-flop antithesis will gain considerable validity. The pressures are now great to force excess labor from farms; these pressures come from high land and other capital costs, large know-how requirements, and other barriers to entry. Also, the farm population is becoming such a small portion of the national population that a sizable percentage can take nonfarm jobs without turning the economy upside down. In fact, a simple linear projection of farm worker numbers indicates no workers in farming by the mid-1980's. This of course is an unrealistic projection, but it does mean that rapid progress is being made in reducing the number of workers and that the absolute number of out-migrants will be able to slow considerably in the future. Signs of a slowdown were apparent in 1967 and 1968.

Increasing Returns to Farm Size

Numerous studies have documented the existence of decreasing average costs and increasing returns to size of farm firms [10]. But the concept has not been related to farm problems. The term "size" rather than "scale" is used. Returns to scale refer to the impact on farm output of a given change in the level of all resources in fixed proportion. Expansion of the farming units does not entail an equal percentage expansion in all resources, and the pure concept of returns to scale is academic, with little relevance to farm policy. The expansion in the farm firm is generally characterized by increasing the proportion of capital to labor and of variable capital to fixed capital. These changes result in a sizable reduction in cost per unit of production.

Evidence of decreasing costs per unit (increasing returns to size) is readily apparent in Figure 2 and Table 1.[6] The cost of all inputs (including the opportunity cost of equity capital and of operator and family labor) per unit of output (including receipts from farm commodities, nonmoney income, and government payments) averaged $2.67 on Class VI farms and $0.91 on Class I farms. Most of the economies of size appear to be achieved by Class II farms, and unit costs decline very slowly beyond an annual output of $30,000 per farm.[7]

The marginal and average revenue curves are indicated by the horizontal dotted line at $1 in Figure 2. The intersection of the revenue curve with the unit cost curve means that farms with sales under $25,000 on the average lost money and did not cover all production costs in 1960. Farms with sales over $25,000 received an economic rent per unit of output equal to the difference between the cost and revenue curves.

It may be said that small farms earned low returns because they paid too much for their land. Land tends to be a complementary input with farm size. There is constant pressure to expand farm acreage to achieve the economies of size so apparent in Figure 2. The savings through

---

[6] Figure 2 is called a "unit" cost curve because it lies somewhere between the concepts of a long-run "average" and "marginal" cost curve. The curve is an average within an economic class of farm but is a marginal curve among classes.

The output-input ratio is defined as gross income from farming divided by the cost of all farm inputs, including the opportunity cost of equity capital and all labor. The labor cost is man-hour requirements in farming multiplied by the central city wage rate adjusted for age, education, and sex. In 1960, the median age of all farm operators was 51 years and median education was 7.8 years. For operators of Class VI farms, median age was 54 years and education was 7.0 years; hence, their parity labor income was reduced accordingly. The opportunity cost for farm operator labor was set at $2.20 per man-hour of farm employment on Class I, II, and III farms; $1.94 per hour on Class IV farms; $1.86 per hour on Class V farms; and $1.80 per hour on Class VI farms. Each man-hour of unpaid family labor was set at $1.60 per hour and each man-hour of hired labor at $1.54 per hour. These estimates are closely in line with 1959 estimates used on a USDA study [25, p. 17]. The average factory wage was $2.61 per hour in 1960 [22, p. 46].

[7] A cutoff of government payments could radically alter the economies of size curve depicted in Figure 2. By letting the parity ratio drop to 74 percent of parity in 1960 (1910–14 = 100) and giving a direct payment (grant) equal to the difference between a horizontal line through I and the unit cost curve multiplied by the units of output, a government program would cause farms to have constant returns to size. All resources would be paid their opportunity cost. Flattening the unit cost curve would cost the U.S. Treasury $10 billion and would remove much of the pressure to consolidate units. Problems of administering such a program would be overwhelming.

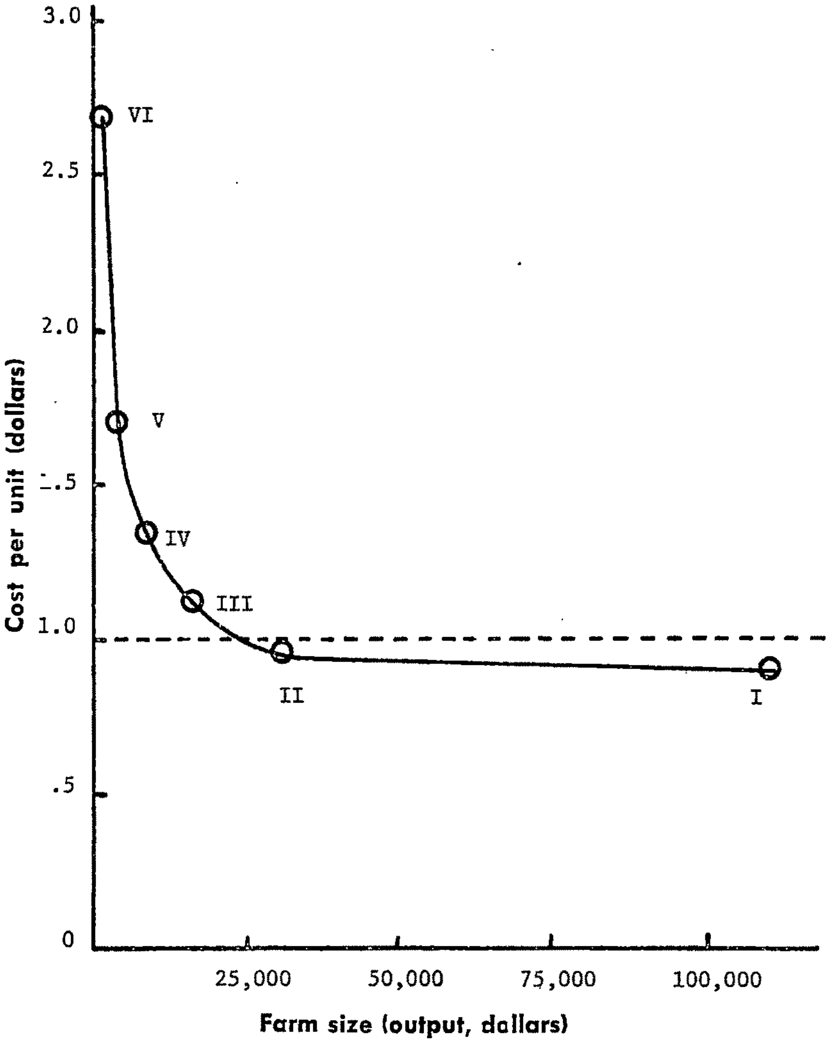

Figure 2. Long-run unit cost of farm production, by economic class of farms in 1960 (Source: Table 1)

greater efficiency are bid into the price of land. The actual price of land tends to be that price which will make all costs, including real estate interest, equal to the value of all farm receipts *on an economic size unit.*

Competition in the land market tends to bid the land price to the point where the return on land will be equal to the return on capital in other uses. A potential buyer who is unwilling to pay this price will find land bid away from him by the investor who wishes to maximize returns. And investors will not pay more than this price because a greater return

Table 1. Output, input, and efficiency by economic class of farms

	Economic class of commercial farms						Noncommercial farms
	I	II	III	IV	V	VI	
1960 input per output (unit cost, dollars)[a]	.91	.95	1.10	1.34	1.69	2.67	2.91
1960 output per input (efficiency, dollars)	1.10	1.05	.91	.74	.59	.37	.34
1960 output if all farm resources would have been used with respective farm-class efficiency (billion dollars)	46.9	44.9	38.8	31.8	25.4	16.0	14.7
Percent of all inputs in respective class of farms:[b]							
1960 (percent)	24.8	15.5	20.6	16.4	10.0	3.5	9.2
1965 (percent)	33.5	19.1	18.6	11.3	6.2	3.9	7.4

Sources [15, 22, 25].

[a] The input-output ratio was computed as follows: costs of land, capital, and labor were totaled and divided by all farm receipts (excluding off-farm income and including receipts from farm products consumed on the farm). In all cases the cost of nonreal estate durable capital was 5 percent interest plus depreciation. The cost of all farm labor was man-hour requirements multiplied by the wage rate of urban wage earners corrected for the age, education, and sex ratio of all farm hired, operator, and family workers.

[b] The 1960 and 1965 estimates are not strictly comparable. The farm dwelling interest charge and 60 percent of the auto interest and depreciation are excluded in 1960 estimates of production inputs but are included in the 1965 estimates because data were inadequate to remove them. Since dwelling and auto inputs tend to be relatively large for small farms, this at least partially explains the incongruously larger percent of inputs on the small Class VI farms in 1965 than in 1960.

can be achieved on nonland investments. The residual return to land tends to be greatest on large farms.[8] The law of one price [13] and the large potential number of investors will ensure that the "high" price for land on large, efficient farms will be the market price of land applicable to all farms.

The small farmer must pay this price or land will be bid away from him by an investor who has or can achieve an economic size unit. Thus, the small farmer tends to actually incur losses if he paid the current land price. And the small farmer who has full equity is losing money if a charge is made for the opportunity cost of his owned land valued at the current price of farm real estate. The tendency in some localities to bid up the price of farmland for potential nonfarm uses also contributes to *apparent* persistent low returns on resources assumed to be used only for farming.

Table 1 and Figure 2 suggest that land was not overpriced at the margin because large farmers were earning returns greater than needed to hold capital in farming. But land was clearly overpriced for an average farmer who had gross sales under $25,000.

The struggle to obtain an economic unit leads to further problems, apparent in Table 1. Output per unit of input is the reciprocal of the long-run cost curve in Figure 2 and essentially is the aggregate production function for farming units. Output per input is 1.10 on Class I farms and is only .37 on Class VI farms. The actual total volume of inputs was $42.8

---

[8] This conclusion holds only on the average. Analysis of data for individual farms by Angus MacDonald of the Farmers Union shows that much variation exists among large farms in net income and resource returns.

billion and the average output per input over all farms was .85 in 1960. Had all inputs been used on farms of Class I efficiency, total output would have been $46.9 billion at 1960 prices.

Class I farms require a substantial input of feed and livestock provided by other farms. Their atypical structure means that if all farms were organized in this manner there would not be sufficient intermediate farm inputs. Class II farms are somewhat more typical and provide a more meaningful measure of the potential gain in efficiency obtainable by a more nearly optimum farm size and combination of inputs. If all farms were organized as Class II farms, the actual 1960 total input would have produced an output of $44.9 billion, or 24 percent above the actual level. If all farms had been organized as those in Class II, only 1.2 million farms could have produced the 1960 output with $34.5 billion of inputs—19 percent less inputs than the actual total 1960 inputs of $42.8 billion. Even discounting the shortcomings of the approach, the results clearly point to large potential efficiency from reorganization of farms into more nearly economic units.

And because most size economies were achieved by Class II farms in 1960, there would have been few economic advantages in having a system of superfarms that would have reduced the number of farms much below 1.2 million. This conclusion applies only to 1960 conditions. In the future the unit cost curve will move to the right, decreasing the number of farms compatible with maximum production efficiency.

The heterogeneous size structure of farms helps to explain why farm land is overpriced for most farmers and why returns are low on farm resources of most farmers. It also is a partial explanation of why farm product prices tend to be low. The continued trend toward larger farms, apparent in the 1960 and 1965 distribution of inputs in Table 1, increases farm output. Based on the distribution for these two years and the output-input ratio by class of farm in 1960, output would increase 6 percent, or 1.2 percent annually from 1960 to 1965, due to the change in size distribution with the same total volume of farm resources as in 1960. Other things equal, this depresses the revenue line in Figure 2 as supply presses demand and creates new pressures for farms to expand in size.

The decreasing cost theory is especially instructive in pointing out the permanency of the problem of low returns. An increase in the product price results in a larger residual return to land. The higher land return causes land prices to rise to the point where farm and nonfarm investors can realize a "parity" return on their investment. This land price is determined at the margin for adequate size units. It follows that small farms, which constitute a large majority of all farms, will receive a low return on all resources when valued at their imputed opportunity costs even with higher farm product prices. The majority of commercial farmers will be underpaid for their resources, whatever the parity ratio, as long as the distribution of farms and the cost curve remain similar to the pattern discussed above.[9]

Imperfect Competition and Low Returns in Farm Resources

Econometric studies show that the farm-nonfarm wage ratio is completely overshadowed by the national unemployment rate in explaining the net outmigration of farm labor [7, Ch. 9]. One conclusion is that there has been a persistent earnings differential attracting farm workers to nonfarm jobs. But employment of farm workers in nonfarm jobs is inhibited by discrimination, union hiring, and other elements of imperfect competition. Minimum wage laws also cause a departure from a market orientation and undoubtedly have inhibited the ability of many farm workers to find nonfarm jobs.

The markets in which farmers purchase inputs and sell commodities are generally characterized by some form of imperfect competition. The actions of a single firm can influence industry price. On the other hand, farming is generally classified as an atomistic industry; the actions of any one farm firm have no perceptible influence on prices in the farming industry.

Substantial research has focused on the market structure, conduct, and performance of firms selling inputs to farmers and marketing farm products [11, 12]. There is considerable evidence from these studies that input supply and marketing firms stabilize price by gearing output to effective demand. The firms, however, are reasonably efficient and in general do not earn profits out of line with other nonfarm industries.

Firms that purchase farm products frequently have a bargaining advantage over farmers, and they can be expected to pay no more than necessary for raw materials. But presence of monopoly elements in marketing firms that process and sell farm produced commodities would not explain low returns to farm resources. It is true that fewer farm resources would be employed than if the marketing sector were atomistic. But if farm resources were mobile, resource returns would equal opportunity costs.

In some instances, farm products may be purchased under monopsony conditions at prices below what the products would bring if sales were made to an atomistic marketing industry. There may be a single processor in a community. But again, this does not lead to low returns if farm resources are mobile. In some instances a monopsonist firm may pay high product prices to bring specialized resources into use, then reduce prices and depend on fixity of the specialized resources to maintain production. Then returns will not cover all production costs if resources are valued at acquisition prices. This latter problem has received little attention in research.

---

[9] This conclusion must be qualified by possible changes in farm structure with a new type of government program or none. The cost curve in Figure 2, constructed for government programs of 1960, would change its shape under other types of programs—by how much is difficult to say.

The labor market is the major potential source of low returns on farm resources through imperfect competition. It can be shown theoretically that monopoly elements, in the form of labor unions selling labor in the nonfarm sector, create a tendency for excess labor and low relative returns on labor in the atomistic farming sector. The extent to which imperfect competition in the nonfarm labor market inhibits farm labor mobility and results in low farm labor earnings has received little attention in research. Another less serious source of possible low farm labor earnings is monopsony buying of labor, say, by a single major firm in an isolated labor market. This could be a large firm or a nonfarm firm hiring farm women and part-time farm operators.

Summary and Conclusions

The three theories advanced to explain persistent low returns in agriculture help to gauge the permanency of farm problems. The resource fixity theory implies that low returns would disappear if the rate at which output-increasing technology is released to farmers would slow, or if demand would increase sufficiently fast in relation to supply so that all farm resources would be valued at their acquisition cost. By this measure, the farm problem is somewhat "temporary."

The decreasing cost theory takes into account the size structure of farms and the valuation of real estate at the margin. Because the slack between returns and nonland costs tends to be absorbed by the land price, it follows that land prices will adjust to make returns equal resource costs at the margin on the efficient size units. As land values adjust, economic size farms will tend to receive an equilibrium (opportunity cost) rate of return on resources within a considerable range of prices received by farmers. It follows that whether product prices are high or low, roughly 90 percent of all farms will receive low returns when the opportunity cost of all resources is taken into account. This points to low returns even on most commercial farms over a long period until farms reach the "flat" portion of the unit cost curve. Farm bargaining power and government income-support programs only temporarily change the picture in Figure 2—these programs raise both total cost and total revenue so that the unit cost and revenue curves remain somewhat stable as the benefits become capitalized into the control instruments.

The third theory, imperfect competition, depicts the farm problem of low returns as virtually permanent, given racial discrimination and the economic structure of resource and product markets. Some forms of imperfect competition lead to relatively low earnings on farm labor, even if all the forces tending toward economic equilibrium work their full effect. Only a change in the structure of markets will alter the result as long as agriculture acts as a residual claimant of the labor force that cannot be used by the nonfarm sector.

The decreasing cost theory of farm problems is related to technology, imperfect competition, and fixed resources. The ability to expand farm size is linked to the ability of farmers to purchase more land. And the ability to buy land and consolidate farms is linked to the rate at which a neighbor can find employment outside of agriculture. The process of adjustment to economic farming units is slowed if operators of inefficient units are unaware of better alternative uses for their resources, if education is inadequate to equip farm people for the exodus, if low income farmers prefer farming as a way of life, and if labor unions and high national unemployment inhibit mobility. Technology, reflected in farm machinery and farm management, has given the shape to the unit cost curve in Figure 2 and is continually changing the shape. In contrast to Cochrane's treadmill theory, the decreasing cost theory does not depend on an inelastic demand and output-increasing technology to explain low resource returns. It derives its substance from labor-saving technology, economies of buying and selling in larger quantities, and labor and machine indivisibilities that give rise to economies of size.

In 1960, only about 10 percent of all farms were in the somewhat flat portion of the cost curve above $25,000 annual output. Public policy must be concerned with getting more of the remaining 90 percent of farms into that category. An unanswered question is how sensitive is the shape of the unit cost curve in Figure 2 and the distribution of farms along the curve to changes in the number of workers in farming. A preliminary conclusion, based on work with 1960 and 1965 data, is that the shape is not highly sensitive to outmovement of workers. Outmovement per se places more farms on the flat portion of the curve, but this tendency is offset to a considerable extent by a shift of the unit cost curve to the right. These problems of low returns on resources are likely to plague agriculture for some time, although workers are moving from agriculture at a rapid rate.

The decreasing cost theory shows how adequate size farming units can be profitable while the farm economy is generally depressed. These profitable firms can be the "mouth" to feed new inputs to an industry that is already oversatiated and can lead to problems of resource fixity.

Because the various theories explaining the persistence of low returns are highly interrelated, and for lack of empirical data on each, it is difficult to pinpoint the portion of the problem of low returns that can be imputed to each causal factor.

Finally, the antithesis of the persistency theories set forth in this paper is that virtually no disequilibrium in the form of low resource returns exists in agriculture. Labor markets function efficiently and quickly to eliminate both earnings disparities and, hence, dynamic disequilibrium, which is continually generated and quickly dissipated. The result is no latent excess labor, measured by low resource returns. If there appear to be measured low resource returns, it is only because those who are doing the measuring assign too high an opportunity cost to farm labor. While some evidence supports this antithesis, the majority of evidence contradicts it. The prematurity of this antithesis suggests that efforts be continued to improve the efficiency of factor markets. If the antithesis is true, then the one major economic problem of commercial operators in a growing farm economy is price and income instability. Even if problems of low average returns are overcome, some form of supply control may be necessary to stabilize farm prices.

Shadow Prices as Member Returns for a Marketing Cooperative*

IAN W. HARDIE

Many marketing cooperatives handle several types or grades of member-supplied products. These cooperatives have to determine the returns to be alloted to each product. Helmberger, Hoos, and Nicholls have solved this problem for a cooperative with a single homogeneous product. However, their models do not extend readily to the multiple product case. This article describes how returns can be simultaneously calculated for each member-supplied product handled by a multiple product marketing cooperative. A linear programming model is first introduced to compute the returns under a set of rather restrictive assumptions. When these assumptions are relaxed, another method of deriving the values is required. Such a method—called the "pooling constraint" method—is presented in the latter part of the article.

IN 1941, Nicholls developed a theory for a marketing cooperative based on a derived demand and factor supply analysis [16]. His theory gave an answer to two of the fundamental questions about marketing cooperatives, namely, "What return should a member receive?" and "How well will the cooperative perform in the market?" However, Nicholls' supply-demand approach was not generally accepted until 1962, when Helmberger and Hoos used it to answer the same two questions in one of the most successful characterizations of a marketing cooperative to date [12, 9].

Helmberger and Hoos were limited by the derived demand construct to the case of a single homogeneous member-supplied product. But many marketing cooperatives receive several different member products and even single product cooperatives receive various grades of raw product with different profit potentials. A model based on homogeneous member products should therefore allow for different types and grades of raw material.

The purpose of this article is to replace the single product derived demand construct with a multiproduct construct based on a linear programming model. For any given quantities of member products, the shadow prices of the multiproduct model will be comparable to the member returns of the Helmberger-Hoos model. However, the two models will not be completely comparable because of the absence of heterogeneity in the one product case and because of the disparate production assumptions underlying the models. These points will be made more clear in the next section where the

Helmberger-Hoos model is collated with a linear programming model containing a single type of constraint. After that the special linear programming model is extended into a multiproduct model made up of many types of linear constraints. But the more general model loses the properties of the special model and can no longer be collated with Helmberger-Hoos model. Consequently, a method is needed to recapture these properties and such a method is introduced in the final section.

Market performance of the multiple product marketing cooperative is not discussed in this article, as it deals only with the derivation of member returns.

Introduction to the Multiple Product Model

Four propositions underlie the demand-supply approach to the marketing cooperative:

(1) A marketing cooperative consists of a set of member firms bound by contract to market their output through jointly-owned facilities operated by a professional management staff.

(2) Management tries to maximize returns to the member-supplied product. The members receive these returns, and management determines each member's share.

(3) The division of returns should meet two criteria: Each unit of homogeneous product should receive the same return, and all of the net proceeds should be assigned to the members.

(4) The interaction between the member firms and the jointly-held organization is enough like a market transaction to be characterized by a demand-supply analysis.

Helmberger and Hoos constructed the following argument founded on these propositions. If the cooperative were interested in profit maximization, its profit function would be:

$$\pi = \overline{P}_y Y - \sum_{i=1}^{n} \overline{P}_i X_i - P_m M - F \tag{1}$$

where

π = profit,
Y = quantity of output produced by the cooperative,
X_i = quantity used of the ith productive factor,
M = quantity used of the member-supplied material,
F = total costs of fixed plant,
P_m = price of M,
$\overline{P}_i$ = fixed price of X_i, and
$\overline{P}_y$ = fixed price of Y.

But the cooperative is a nonprofit concern. Consequently, π should be set equal to zero. If, in addition, M is replaced by $\overline{M}$, that is, if the amount of member product available for processing is assumed to be fixed, "cooperative surplus" can be defined to be:

$$S = P_m\overline{M} \tag{2}$$
$$= \overline{P}_y Y - \sum_{i=1}^{m} \overline{P}_i X_i - F.$$

Maximization of the member returns gained from the given member product is equivalent to maximization of the cooperative surplus.

To maximize S, first minimize total variable costs:

$$C = \sum_{i=1}^{m} \overline{P}_i X_i \tag{3}$$

subject to the production function:

$$Y = Y(X_1, X_2, \cdots, X_n \mid \overline{M}, Z) \tag{4}$$

where Z represents fixed plant. This gives total variable cost as a single valued function of output:

$$C = C(Y). \tag{5}$$

Upon substitution into the cooperative surplus expression,

$$S = \overline{P}_y Y - C(Y) - F, \tag{6}$$

the surplus can be maximized with regard to output.

Let Y_0 represent the output that maximizes S, and let ATC_0 be the corresponding average total cost of production. Then, the maximum cooperative surplus is:

$$S = (\overline{P}_y - ATC_0) Y_0 \tag{7}$$

and the maximum net return accruing[1] to each unit of member product is:

$$P_{m0} = (\overline{P}_y - ATC_0) Y_0 / \overline{M}. \tag{8}$$

Parametric variation of $\overline{M}$ in equation (2) would yield a (short-run) member returns schedule. Further, when M is set equal to $\overline{M}$ in the profit function (1) and profit is maximized, P_{m0} is the average revenue product of $\overline{M}$. Thus, maximization of the joint operation's profit will also yield the member return, and parametric variation of $\overline{M}$ in the profit function will yield the member returns schedule.

---

[1] The members are not likely to immediately receive all of P_{m0}. Part of the member return may be retained in a revolving fund to provide working capital for the cooperative. How much to retain, how long to retain it, what effect these retainings have on member supplies, etc. are important questions that are left unanswered in this article. Incorporation of these decisions into a cooperative model will not be easy, but further work in this area will be vital to a good understanding of a marketing cooperative. See Knutson [13, pp. 114–117].

On the strength of these findings, the proposed multiproduct model uses maximum profit for an objective. It also treats the member products parametrically. However, the multiple product model breaks with the production assumptions of the single product model; the production function of the cooperative's joint plant is assumed to be linear and homogeneous with discontinuous factor substitution so that the model can be put into a linear programming framework [1, pp. 23–31].

One of the motivating reasons for using linear programming is the Helmberger-Hoos treatment of the raw material as a limitational input. With its lack of a market price and fixed total available quantity, a limitational input is the type of input handled explicitly by a linear programming model [1, pp. 16–23]. The other motivating reasons are sixfold. The parametric variation of $\overline{M}$ in the Helmberger-Hoos model has an analogue in the parametric linear programming procedure. Linear programming models are among the most simple multiple product models. They are widely used in applied studies, are well explained in the literature, and are easily solved by the Simplex Method. Furthermore, they can handle large numbers of variables and equations, an important attribute when working with a large complex marketing cooperative.

Two other suppositions will help introduce the proposed model. The average variable cost of producing and selling each cooperative's finished products is assumed to be known and constant. All fixed costs are presumed to be allocable among the final products.[3] With these assumptions, the model of the joint operations of the marketing cooperative can be expressed as:

$$\begin{aligned} &\text{Maximize:} && q_0 = R_1'Q_1 \\ (9)\qquad &\text{Subject to:} && A_{11}Q_1 = X_1 \\ &&& Q_1 \geq 0 \end{aligned}$$

where

$Q_1 \equiv [q_j]$, an nth order column vector.

For the purposes of this section, the (variable) q_j represent either quantities of finished products or quantities of unused member products.

$R_1 \equiv [r_j]$, a $n \times 1$ vector.

r_j is interpreted for the present to be the net revenue gained from a unit of the jth finished product. $r_j = p_j - c_j$, where p_j is the (fixed) price and c_j is the (fixed) average total cost of finished product j.

---

[2] The problem of allocating the overhead is difficult and is not solved by the multiple product model. All that is accomplished by the model is to let the overhead be allocated among the finished products instead of the member products—a division that is more likely to be in line with the accounts of the cooperative.

A r_j associated with an unused member product is assumed to be zero.

$X_1 \equiv [x_i]$, of order $m \times 1$.

x_i, until redefined, is the quantity of a raw product supplied to the cooperative by members.

$A_{11} \equiv [a_{ij}]$, a matrix of order $m \times n$.

a_{ij} is a fixed input-output coefficient and is interpreted as the amount of x_i associated with a unit of q_j. The column of a_{ij}'s corresponding to a particular q_j is called an "activity."

Assume there is at least one set of nonnegative values for Q that satisfies the constraints of model (9), and let the constraints be linearly independent. Then the fundamental theorem of linear programming guarantees the existence of an optimum solution with at least $n-m$ zero-valued variables. Model (9) can be rearranged to separate these $n-m$ zero-valued or "nonbasic" variables from the other "basic" variables. When this division is made, the basic variables will be renamed:

$Y \equiv [y_k]$ is the mth order column vector of basic variables. The basis—that set of input-output coefficients associated with the basic variables—shall be represented by the matrix B of order m, where

$$B \equiv [a_{ij}^*] \equiv [b_{ij}]$$

and a_{ij}^* is a coefficient of y_k. Elements from the inverse basis matrix will have superscripted indices.

Let Y be an optimum solution of the model (9). Then

$$Y = B^{-1}X_1, \tag{10}$$

and y_0, the maximum value of q_0, is

$$y_0 = V'Y \tag{11}$$

where

$V \equiv [v_j^*]$, an $m \times 1$ vector of the r_j (net revenues) associated with the basic variables.

The optimum solution of the dual problem of model (9) would be

$$\Pi = V'B^{-1} \tag{12}$$

where

$\Pi = [\pi_{11}]$, an $m \times 1$ vector of shadow prices associated with the x_i (raw materials).

Since

$$\Pi'X_1 = V'B^{-1}X_1 = V'Y = y_0, \tag{13}$$

all of the joint organization's profit is assigned to the members. Moreover, solve for any of the shadow prices, e.g., the first:

$$\begin{aligned}\pi_1 &= (y_0 - \sum_{i=2}^{m} \pi_i x_i)/x_1 \\ &= (\sum_{k=1}^{m} (p_k - c_k)y_k - \sum_{i=2}^{m} \pi_i x_i)/x_1\end{aligned} \tag{14}$$

and the similarity becomes evident between the shadow prices and the member return (p_{m0}) of the Helmberger-Hoos model. $\pi_1 x_1$ is total cooperative surplus minus the surplus assigned to the other member products.

The member return of the single raw product model incorporates the three criteria given earlier; namely, maximum cooperative surplus, equal payments for homogeneous products, and allocation of all earnings to members. The shadow prices meet these three criteria but they also introduce a fourth: a criterion for the division of total profit among the heterogeneous classes of member products.

Total profit is divided on an opportunity cost basis, since the raw products are not given market prices. When the raw materials are assigned an opportunity cost equal to their shadow prices, the net revenue from any unit of manufactured output is equal to the cost of utilizing the raw materials in its manufacture. Thus, the shadow prices equate marginal revenues with marginal "full" costs (costs including shadow prices) and average revenues with average full costs. The new criterion emerges from the equality of the averages: Each member receives the cooperative surplus earned by his products.[3]

The shadow price equations show how the multiproduct model introduces this fourth criterion. Since

$$y_k = \sum_{i=1}^{m} b^{ki} x_i, \tag{15}$$

$b^{ki}x_i$ is the contribution of raw product i to finished product k, the b^{ki} weights being determined simultaneously from the input-output coefficients of the optimum basis. When this contribution is multiplied by v_k, it becomes a monetary value; and when these monetary contributions are summed over all of the finished products, a shadow price emerges:

$$\sum_{k=1}^{m} v_k b^{ki} x_i = \pi_i x_i. \tag{16}$$

---

[3] Division of the total cooperative surplus among the various member products is part of the "pooling problem" of a marketing cooperative. Most agricultural products can not be classified into completely homogeneous categories or pools. Consequently, the number of pools to be used becomes an economic question in which the cost of more pools must be balanced against the differing profit potentials of the materials within each pool. Sosnick [17] shows how to combine fine subclassifications of member products into pools, once the return accruing to each subclassification is known. The multiproduct model shows how to determine the return accruing to each pool of raw products, once the pools are known. Both approaches partly solve the pooling problem and, if combined successively, may be a way to completely answer it.

total cooperative surplus minus the surplus alloted to the other member products.

The reason why these two criteria are violated can be illustrated by the following example. Suppose one of the final products does have a downward-sloping demand curve and that this is partly accounted for by using the first of the aforesaid alternatives. Thus, a constraint is added to limit the output of this product, say to the quantity x_{m+1}. Any constraint that is binding will (most likely) have an associated shadow price that is positive.[8] Let π_{m+1} be the (positive) shadow price of the added constraint. Then equation (13) would become:[9]

$$\Pi^{o\prime}X_1 + \pi_{m+1}x_{m+1} = y_0^{\circ} \tag{17}$$

and the returns allocated to the raw products would be less than the total profit. Similarly, equation (14) would become:

$$\pi_1^0 = \left[\sum_{k=1}^{m} (p_k - c_k)y_k^0 - \sum_{i=2}^{m} \pi_i^0 x_i - \pi_{m+1}x_{m+1} \right] / x_1. \tag{18}$$

π_{m+1} is the increase in profit which could be obtained if an additional unit of the finished product could be sold at the price entered in the model. But this "cost" of not facing a perfectly elastic demand should not influence the distribution of realizable profits to the members and, as equation (18) shows, it does.

The "pooling constraint" method modifies the augmented model in order to remove the effect of shadow prices like π_{m+1}. Before this method is described, however, model (9) needs to be converted into an augmented model. To do this, let $\mu > m$ and $\eta > n$ and let:

$$X \equiv \begin{bmatrix} X_1 \\ X_2 \end{bmatrix},$$

X_1 is the mth order vector of member-supplied products defined in model (9). X_2 has $\mu - m$ elements and is a vector of "other limitational inputs."

$$Q \equiv \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix},$$

Q_1 was defined earlier. Q_2 is the $(\eta - n)$th order vector of variables which are added to the original multiproduct model.

---

[8] This ignores the situation where a constraint is binding and the shadow price is zero. In such a case, the augmented model's solution would meet the criteria of model (9).

[9] The augmented model would have a different set of shadow prices for the member products; hence, Π is replaced by $\Pi^o = [\pi_i^o]$. Also, the production plan and profit would be different; therefore y_0 is replaced by y_0^o and y_k by y_k^o. y_k is also replaced by y_k^o in equation (18).

$$R \equiv \begin{bmatrix} R_1 \\ R_2 \end{bmatrix},$$

R_2 contains the coefficients of the objective equation associated with Q_2.

$$A \equiv \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix},$$

A is a $\mu \times \eta$ matrix of input-output coefficients. The partitions are between the mth and the $(m+1)$th rows and the nth and the $(n+1)$th columns. The augmented model is:

$$\text{(19)} \qquad \begin{aligned} \text{Maximize: } & R'Q \\ \text{Subject to: } & AQ = X \\ & Q \geq 0. \end{aligned}$$

A "hat" will be used to denote "optimum and basic" for the augmented model. Thus:

$\hat{B}(\equiv [\hat{b}_{ik}]\ i, k = 1, \cdots, \mu)$ is the optimum basis of the augmented model.
$\hat{Y}(\equiv [\hat{y}_k]\ k = 1, \cdots, \mu)$ is the vector of the augmented model's optimum basic variables.
$\hat{V}(\equiv [\hat{v}_k]\ k = 1, \cdots, \mu)$ is the vector of basic r_j's.

The shadow prices of model (19) will be represented by:

$$\hat{\Pi} = \begin{bmatrix} \hat{\Pi}_1 \\ \hat{\Pi}_2 \end{bmatrix},$$

$\hat{\Pi}_1$ is the vector of member product shadow prices. $\hat{\Pi}_2$ contains the shadow prices of the other limitational inputs.

The Pooling Constraint Method

Equation (13) embodied two of the four criteria of the original multiproduct model. It indicated that all of the cooperative surplus is to be returned to the members and that each member is to receive the surplus added by his products. For the augmented model, the equation corresponding to (13) is:

$$\text{(20)} \qquad \hat{\Pi}_1{}'X_1 + \hat{\Pi}_2{}'X_2 = \hat{V}'\hat{Y} = \hat{y}_0.$$

However, this equation does not embody the two criteria unless $\hat{\Pi}_2{}'X_2$ happens to be zero.

A zero value for $\hat{\Pi}_2{}'X_2$ is unlikely if the added constraints effectively restrict the augmented model's solution. Thus, the two criteria are not likely to hold. Suppose, though, that the augmented model is reformulated so that X_2 is replaced by a null vector. Then the inner product of $\hat{\Pi}_2$ and X_2 will always be zero and the criteria will be recaptured. This is the basic approach of the pooling constraint method.

The method requires the addition of a variable and a constraint to the augmented model. The resulting model, called the "pooling model" is:

Maximize: $R'Q$

$$\text{Subject to: } \begin{bmatrix} \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} & \begin{bmatrix} 0 \\ -X_2 \end{bmatrix} \\ [D_1'] & [D_2] \end{bmatrix} \begin{bmatrix} \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} \\ q_{\eta+1} \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} X_1 \\ 0 \end{bmatrix} \\ 0 \end{bmatrix} \tag{21}$$

and to

$$Q,\ q_{\eta+1} \geq 0.$$

where

$D_1 \equiv [d_j]$ $j = 1, \cdots, \eta$.

$E \equiv [d_j^*]$ is a $\mu \times 1$ vector of the d_j coefficients associated with basic variables of the augmented model.

$D_2 \equiv -E'\hat{Y}$.

$q_{\eta+1}$ is called the "pooling variable" and the last constraint is called the "pooling constraint." The pooling model assumes that the augmented model has already been solved. Otherwise, D_2 will not be known. It also assumes the pooling constraint is linearly independent of the other constraints.

The augmented model and the pooling model will have the same optimum primal solution if the pooling variable is equal to one. To verify this, consider the following argument. If $q_{\eta+1} = 1$, the only difference between the two models is the pooling constraint. The addition of a constraint can never better a model's optimum solution. Moreover, the optimum solution found for the augmented model satisfies the pooling constraint. Consequently, this solution must also be an optimum solution for the pooling model.

The pooling variable will equal one if the optimum basic variables of the augmented model are the other basic variables of the pooling model. To demonstrate this, $q_{\eta+1}$ needs to be incorporated into the optimum basis of the augmented model. Let $\overline{B}$ denote the expanded optimum basis formed by adding the coefficients associated with the pooling constraint and pooling variable:

$$\overline{B} = \begin{bmatrix} \hat{B} & \tilde{X}_2 \\ E' & D_2 \end{bmatrix} \tag{22}$$

where

$$\tilde{X}_2 = \begin{bmatrix} 0 \\ -X_2 \end{bmatrix}.$$

The expanded basis can be inverted by the partitioned inverse method [6]:

$$\overline{B}^{-1} = 1/d\begin{bmatrix} \hat{B}^{-1} + \hat{B}^{-1}\tilde{X}_2E'\hat{B}^{-1} & -\hat{B}^{-1}\tilde{X}_2 \\ -E'\hat{B}^{-1} & 1 \end{bmatrix} \tag{23}$$

d is the determinant of $\overline{B}^{-1}$ and

$$\begin{aligned} d &= D_2 - E'\hat{B}^{-1}\tilde{X}_2 \\ &= -E'\hat{B}^{-1}X - E'\hat{B}^{-1}\tilde{X}_2 \\ &= -E'\hat{B}^{-1}\tilde{X}_1 \end{aligned} \tag{24}$$

where

$$\tilde{X}_1 = \begin{bmatrix} X_1 \\ 0 \end{bmatrix}.$$

The primal solution of the pooling model associated with this basis will be:

$$\overline{Y} = \overline{B}^{-1}\overline{X} \tag{25}$$

where

$$\overline{Y} \equiv \begin{bmatrix} Y \\ y_{\mu+1} \end{bmatrix}$$

$$y_{\mu+1} = q_{\eta+1}$$

$$\overline{X} \equiv \begin{bmatrix} \tilde{X}_1 \\ 0 \end{bmatrix}.$$

When $y_{\mu+1}$ is picked out of the primal solution:

$$y_{\mu+1} = \begin{bmatrix} \dfrac{-E'\hat{B}^{-1}}{-E'\hat{B}^{-1}\tilde{X}_1} & \dfrac{1}{-E\hat{B}^{-1}\tilde{X}_1} \end{bmatrix} \begin{bmatrix} \tilde{X}_1 \\ 0 \end{bmatrix} = 1, \tag{26}$$

it is easy to see that the pooling variable equals one when the $\hat{y}_k$ are the other basic variables of the pooling model.

The solution to the pooling model can be found by using the Simplex Method of solving a linear programming problem. Four steps are required:

(1) Solve the augmented model by the Simplex Method.
(2) Delete all nonbasic variables from the optimum solution of the augmented model.
(3) Calculate D_2 and form the pooling model by adding the pooling constraint and pooling variable.
(4) Solve the pooling model by the Simplex Method.

The primal solution of the pooling model is the primal solution of the augmented model plus the pooling variable. But the pooling model's dual solution will generate shadow prices for the member products that totally exhaust profit:

$$\hat{y}_0 = \bar{\Pi}'\bar{X} = \bar{\Pi}_1'X_1 \tag{27}$$

where

$\bar{\Pi}$ is the $\mu+1$ vector of the pooling model's shadow prices.

$\bar{\Pi}_1$ is the column vector of the first m components of $\bar{\Pi}$.

The first m shadow prices can be extracted from the dual solution of the pooling model and interpreted. Since

$$\begin{aligned} \bar{\Pi}' &= [\hat{V}' \quad 0]\bar{B}^{-1} \\ &= 1/d[\hat{V}'\hat{B}^{-1} + \hat{V}'\hat{B}^{-1}\bar{X}_2E'\hat{B}^{-1},\ -\hat{V}'\hat{B}^{-1}\bar{X}_2] \\ &= 1/d[\hat{\Pi}' + \hat{\Pi}'\bar{X}_2E'\hat{B}^{-1},\ \hat{\Pi}'\bar{X}_2], \end{aligned} \tag{28}$$

the shadow prices of the raw products will be:

$$\bar{\Pi}_1' = \hat{\Pi}_1 + (E'B_1/E'B_1X_1)\hat{\Pi}_2'X_2 \tag{29}$$

where

B_1 ($\equiv[\hat{b}^{ih}]$ $i=1, \ldots, \mu$, $h=1, \ldots, m.$) is the first m columns of $\hat{B}^{-1}$.

Recall that $\hat{\Pi}_1$, $\hat{\Pi}_2$, X_1, and X_2 are all from the augmented model and that $\hat{\Pi}_2'X_2$ is the total profit assigned the limitational "inputs" that were *not* member products. Thus, the new member product shadow prices are made up of $\hat{\Pi}_1$—the member product shadow prices of the augmented model—plus a proportion of $\hat{\Pi}_2'X_2$.

The proportions are obviously influenced by E. The vector E and D_1 could come from any linearly independent pooling constraint. However, only one pooling constraint will meet the fourth criterion of the original multiproduct model. This is the constraint where

$$D'_1 = [1, \cdots, 1]. \tag{30}$$

Let D_1 and E be vectors of ones. Then:

$$E'B_1 = \left[\sum_{k=1}^{\mu} \hat{b}^{k1},\ \sum_{k=1}^{\mu} \hat{b}^{k2},\ \cdots,\ \sum_{k=1}^{\mu} \hat{b}^{km} \right], \tag{31}$$

that is, $E'B_1$ is the column sums of the first m columns of $\hat{B}^{-1}$. Next, recall that

$$\hat{y}_k = \sum_{i=1}^{\mu} \hat{b}^{ki}x_i$$

and that the weights in the weighted sum of inputs making up $\hat{y}_k$ are the linearly transformed input-output coefficients of the optimum basis. Since the first m of the inputs are the member products, the numerators of the proportions are the contributions of a unit of member product h to all μ of the optimum basic variables. Similarly, the denominator is the contribution of all of the member products to all of the $\hat{y}_k$.

The shadow prices assigned to X_2 are pooled into a single value and then redistributed to the members according to the proportionate contribution of each member product. Thus, a total monetary value and proportions replace the sum of monetary contributions making up the shadow prices of the original model (see equation (16)). But both models use the contribution of the member product to the optimum basic variables to distribute the cooperative's surplus. Consequently, both return to each member what his products add to the cooperative surplus.

The choice of D_1 as a vector of ones plays a critical role in the pooling constraint method. D_1—and hence, E—could be multiplied by any scalar without affecting the pooling model's primal or dual solution. But if the d_j components chosen for D_1 are not all equal to the same numbers, some of the raw product returns will be enhanced at the expense of the others. In such a case, the relative values assigned to the raw products would not be completely determined by the linearly transformed input-output coefficients, and the fourth criterion of the original multiproduct model would not hold.

The cooperative's management might prefer a set of unequal coefficients if the resulting returns would encourage the members to supply a more salable mix of raw products. On the other hand, some of the members might feel that such coefficients create inequitable member returns.

The pooling constraint method can be applied for any D_1, unless the pooling constraint turns out to be linearly dependent. When this happens, $E'B_1X_1$ is zero, and the second term of equation (29) is undefined. There is no simple way to tell when $E'B_1X_1$ will equal zero, but if it does, the coefficients of the pooling constraint would have to be redefined before the pooling constraint method could be used.[10]

One alternative specification for D_1 would be to assign to a variable representing a finished product a coefficient of one and to specify a coefficient of zero for the other variables. Then the proportions of equation (29) would include only the contribution of the raw products to the finished products and not their contribution to all of the variables. This alternative is less desirable because it arbitrarily removes some of the effects of the member products on the total cooperative surplus. Nevertheless, it may solve the problem of a linearly dependent pooling constraint.

---

[10] If no desirable alternative to the chosen A_{21} exists, the components of A_{21} could be perturbed slightly. (See [2, Ch. 10] for an example of a perturbation procedure.) Perturbing the components is a poor option, however, for the proportions of equation (27) are highly sensitive to the choice of perturbed coefficients.

The pooling constraint method might be applied to a convex programming problem. Hartley and Hocking use a linear model to approximate the nonlinear problem in their method of solving convex programming models [10]. This linear programming model can be converted into a pooling model. Should the economic meaning of the pooling model turn out to be reasonable, the assumption of fixed production coefficients and discontinuous factor substitution would no longer be necessary. The convex model might provide a good foundation for a study of the market performance of a multiproduct marketing cooperative.

Summary and Conclusion

This article has been concerned with the question: "What returns should a member receive from a multiple product marketing cooperative?" Multiple raw products were emphasized because the single member product case had already been worked out by Helmberger, Hoos, and Nicholls. The article:

(1) Summarized the Helmberger-Hoos single product model.
(2) Introduced a special multiproduct model formulated as a linear program.
(3) Compared the special model with the Helmberger-Hoos construct.
(4) Extended the special multiproduct model into an augmented model which is more amenable to empirical application, but which lost two of the desirable properties of the special model.
(5) Developed the pooling constraint method to recapture these properties.

Three criteria for the member returns underlie the Helmberger-Hoos model. They are: (1) maximize the total cooperative surplus (i.e., the total amount to be returned to the members), (2) return all of the cooperative surplus to the members, and (3) allocate the same return to every unit of a homogeneous member product. The multiproduct model introduced different types and grades of raw products and so needed an additional criterion: (4) pay each member product what it contributes to the cooperative surplus.

Formulating the multiple product model as a linear program is attractive from the viewpoint of isolating the fourth criterion. It also is useful when doing an empirical study [8]. Although longer run conclusions about the cooperative's market performance can not be readily drawn for the linear model, as they can be for the Helmberger-Hoos and Nicholls models, the linear programming approach presented in this article may be a start toward a theory of a multiple product marketing cooperative.

A Conceptual Framework for Analyzing Economies of Vertical Integration*

SAMUEL H. LOGAN

The objective of this paper is to develop a framework for quantitatively analyzing economic aspects of vertical integration by a firm. The model is based on a firm that possesses a multidimensional or lexicographic utility function in which some optimizing criteria are established for several variables. The two particular firm goals considered in this case are maximization of return on investment and reduction of short-run risk. The effects of integration are considered first in terms of changes in costs under conditions of certainty and then in terms of changes in costs and/or uncertainty under imperfect market coordination. The latter situation occurs when the market mechanism is inadequate with respect to communicating the necessary or correct requirements of price and product specification.

VERTICAL coordination of production, processing, and marketing activities has been of concern to agricultural economists, businessmen, and government policy makers for some time. The continued growth of large, integrated operations has increased the importance of this subject area, yet most of the published research in this field has been descriptive in nature or has been limited to one phase of the economics of integration e.g., cost reduction. The net result has been a continuing void in the availability of guide lines for analyzing the economic aspects of vertical integration for either business executives or governmental administrators.

Studying economic aspects of vertical integration can be approached from two directions: (1) from the viewpoint of the firm that is initiating the integration, or (2) from the macro or industry level in terms of social costs and benefits. The former considers individual utility functions; the latter emphasizes the social welfare function.

In order to understand fully the social aspects of integration, we must first consider the consequences, if any, of vertical integration on efficiency of the firm's operation or on the entrepreneur's utility function. This paper concentrates on this first step by developing a framework for analyzing quantitatively the value of vertical integration at the firm level.[1]

Integration Defined

Integration is part of the larger spectrum of coordination of the various levels of production and processing between the initial producer and the final consumer. The definition followed in this paper is one offered by Mighell and Jones [19]—that integration is the combination of two or more levels of activity into one firm. Thus integration is the extension of a firm's administrative decisions into areas of market coordination typically allocated to the free market mechanism.

Integration and Firm Growth

The basic foundation for studying vertical integration can be found in the literature on firm growth theory typified by Penrose [21], Halter [13], Coase [6], Farrar [10], and Baumol [3]. The development of firm growth theory has underscored the inadequacy of profit-maximization as the sole objective of the firm and hence as a tool for explaining and predicting behavior of firms. Certainly, decision criteria of a nonprofit nature play an important, if not the major role, in the development of vertically integrated operations. While vertical integration may not alter total sales significantly (if the output of one stage is consumed internally by another stage), it may affect both the profits and risk facing the firm, variables which may rank high on a particular firm's utility function.

When several objectives help determine the firm's course of action, the firm possesses a utility function with multiple dimensions. Thus, a firm may try to maximize its rate of growth, subject to constraints on risk, rate of return on investment, sales, or profits. The general utility function, for example, might take the form:

$$U = f(Z_1, Z_2, Z_3)$$

where

U = utility of the firm,
Z_1 = rate of return on investment,
Z_2 = sales, and
Z_3 = some measure of risk.

Lexicographic utility functions

Maximization of multidimensional utility functions can be accomplished when these goals can be ordered lexicographically [11, 9, 8, 17]. Such lexicographic orderings establish priorities for achieving the separate goals. Thus, the first goal (e.g., a certain level of net income) must be met before the second goal (e.g., a higher share of industry volume) becomes of dominant importance. In this manner, the firm can possess several objectives, but because of the lexicographic preferences, there is a basis for orderly decision making if two or more goals are in conflict.

One of the major properties of lexicographic utility functions, as outlined by Encamación [9] and Ferguson [11], is the constancy of utility from Z_1 after it reaches the "satisfactory" level Z_1^*. This assumption forces an indifference map, such as that in Figure 1, and may be unrealistic, since utility in either section of the utility surface is changed by altering only one of the variables regardless of what happens to the other.

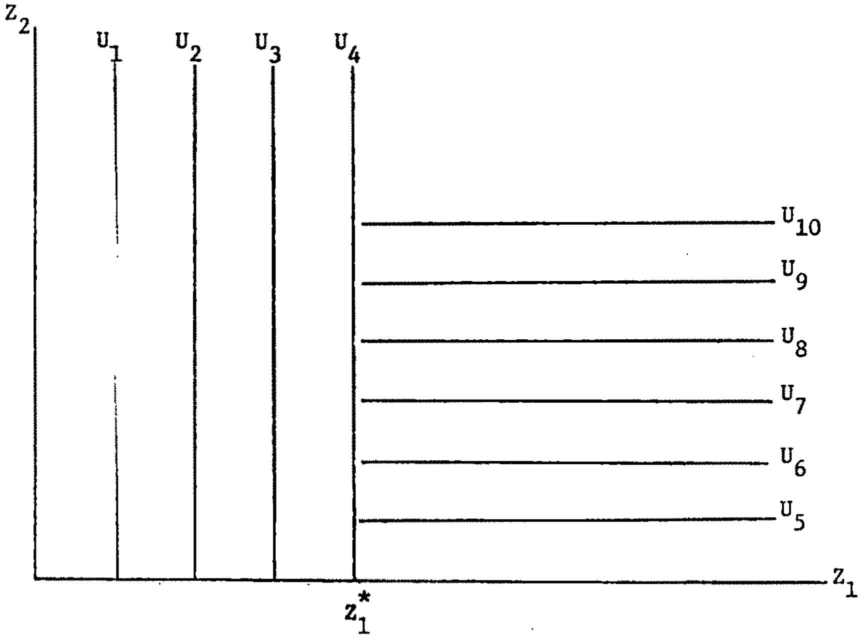

Figure 1. **Lexicographic indifference surface for Z_1, Z_2 without substitution between Z_1 and Z_2**

Although the indifference surface may be discontinuous where $Z_1 = Z_1^*$, it would seem more reasonable to allow some substitution beyond that point (Figure 2). While either assumption is arbitrary, permitting some substitution of Z_1 for Z_2 after the satisfactory level for Z_1 has been reached would seem to be the more general case, although it does not provide as concise a framework for maximizing utility.

Return and risk as utility variables

The model to be developed below is based on two major goals: (1) risk reduction and (2) growth in some quantitative measure of achievement,

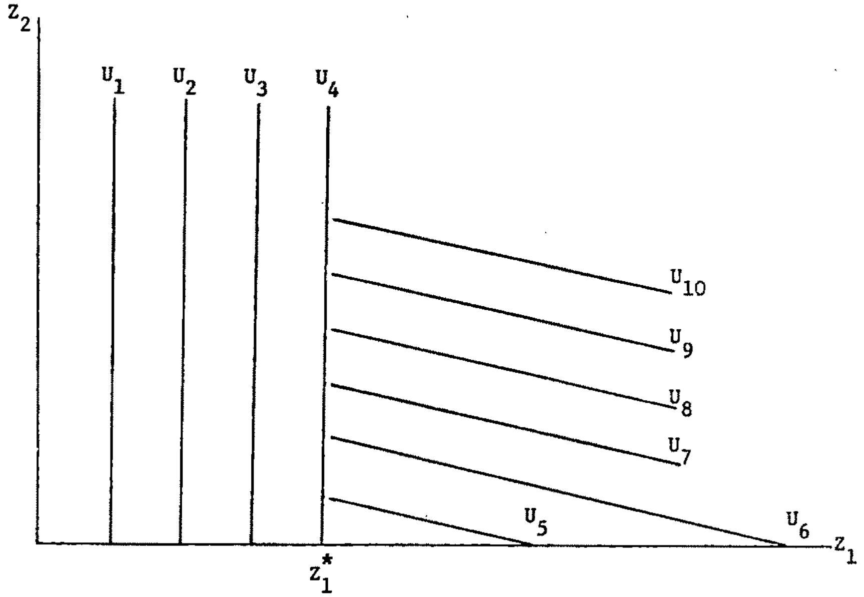

Figure 2. **Lexicographic indifference surface for Z_1, Z_{2*} with substitution between Z_1 and Z_2 for $Z_1 \geq Z_1^*$**

return on investment in this case.[2] Using certainty equivalence techniques [17, 10], we can consider the firm's general utility function as:

$$g = f(V, E(r))$$

where

g = utility,
$E(r)$ = the expected return on investment, and
V = the variance of the return on investment, i.e., the risk factor.

If the firm's policy is to hold risk (V) within some boundary level, k, or if the ratio of variance to expected value must be less than or equal to some level, h, then the firm's utility function has lexicographic ordering with two components.[3] In the latter case, illustrated in Figure 3, the general form of the lexicographic utility function is:

---

[2] Return on investment is an arbitrary measure of financial success. We could just as reasonably have included profits, sales, growth in assets, etc. To this extent the reader should not consider return on investment as a limiting assumption.

[3] Baumol, [2] proposes selection of investments on the basis of $E(r) - K\sqrt{V}$ where K is a constant. This criterion equates the degree of risk to be considered with each investment since the probability that the return will fall below $E(r) - K\sqrt{V}$ is the same for a given K. Baumol's criterion eliminates some of the decision problems found in Markowitz's procedure and could be used in the above format rather than the $V/E(r)$ ratio.

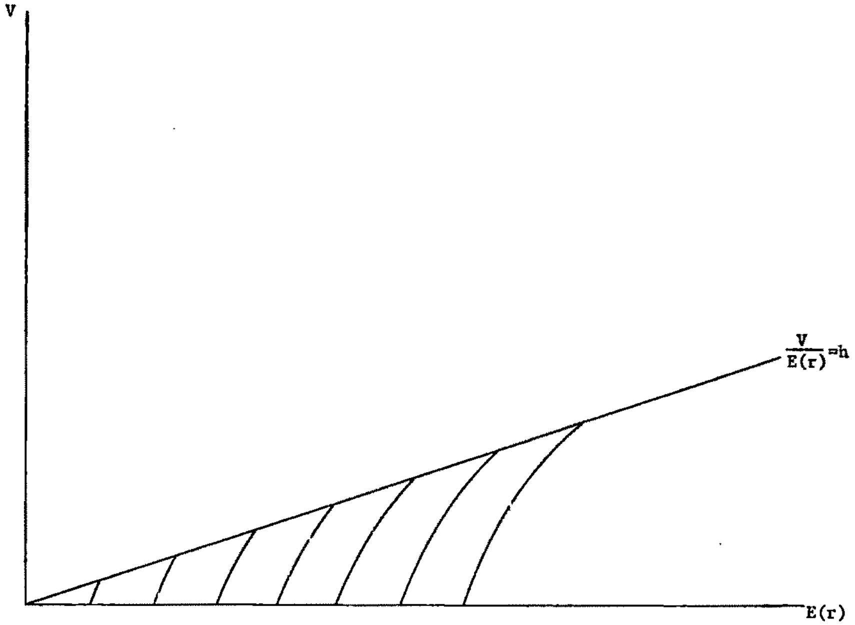

Figure 3. **Indifference curves showing points of equal utility between V and $E(r)$ with a constraint that $V/E(r) \leq h$**

$$U = f(Z_1, Z_2)$$

where

Z_1 = ratio of variance (risk) to expected return on investment and
Z_2 = expected return on investment.

The first constraining condition is that Z_1 must be less than $Z_1^* = h$. Thus, all investment alternatives falling to the left of the ratio constraint line, $V/E(r) = h$, are infeasible to the firm. In the feasible area, some substitution between V and $E(r)$ has been included, indicating that a lower risk investment is preferred to a higher risk venture, given the same expected return on the investment.

Multiple Time Periods

Decisions on long-term investments (including integration) must consider the cash flows or returns generated over time by the investment. These flows, in turn, can be used to estimate the rate of return on investment or the present value of the stream of cash flows (Spencer and Siegelman [25]) for purposes of comparing investment alternatives.

A complete model of firm growth by integration would include the multiple time periods; however, for the purposes of exposition, the developments that follow center on single time period analysis. The results can be generalized to include the time as a relevant variable.

Long-run investment risk differs somewhat from risk for short-run single periods. Long-run risk, for instance, might include changes in consumer preferences, technological obsolescence, etc., whereas the short-run risk might be more closely associated with price and supply fluctuations or quality control of inputs.

Let us consider, then, the components of the utility function that appear applicable in the case of vertical integration. Initially we shall restrict ourselves to the situation in which certainty prevails; then we shall turn to the more general case including short-run risk.

Certainty and the Rate of Return

The nature of the return on investment from integration depends on (1) whether the two levels of activity to be integrated are independent of one another (i.e., decisions at one level do not affect decisions at the other level) or (2) whether interdependencies exist between the two that can be exploited. Koopmans [15] has shown that, if activities are independent, decentralized decision making affords efficient allocation of resources. In this case, the expected return from integration results simply from the profits of the integrated operation itself; costs and revenues at all levels remain the same—the ownership merely has changed. When the levels are interdependent, better marketing opportunities and market control may increase joint revenues of production.[4] Similarly, the total joint costs for all levels of integrated activity may be reduced because of interdependent technological conditions.[5]

In the first case, the expected total return from the two integrated activities would be

$$E(r_1 + r_2) = E(r_1) + E(r_2).$$

Interdependency, however, may involve a change in the population by either increasing revenues or reducing costs. Assuming costs (revenues) are reduced (raised) by a constant amount k for the first activity, the expected total return is

$$E(r_1 + k + r_2) = k + E(r_1) + E(r_2).$$

The expected return to investment that may be attributable to integration, then, would become

$$E(r_1 + k + r_2 - r_1) = E(r_2 + k) = E(r_2) + k,$$

where the firm at level 1 is doing the integrating.

---

[4] See, for example, the study by Taylor and Pasto [26] on vertical integration and multiple pricing in the maple syrup industry.

[5] Mueller and Collins [20].

Because much of the integration in agriculture is aimed at obtaining a supply of inputs, we shall focus our attention on cost reduction, although this formulation should be applicable to the other two areas also.

Intrafirm integration

At each level of activity in producing, processing, and marketing a commodity, the business operation is composed of several processes. Thus, we might divide firm operations into five basic categories: (1) procuring inputs, (2) financing both short- and long-run operations, (3) producing the product, (4) marketing the final good, and (5) managing the entire process. These functions must also be integrated into a harmonious combination at the firm level (French, Sammet, and Bressler [12], and Danø [7]).

Define the following cost functions:

(a) Finance

$$X_1 = f_1(q, k \mid h),$$

(b) Procurement

$$X_2 = f_2(q, v_1 \cdots v_n, X_1 \mid h),$$

(c) Production

$$X_3 = f_3(q, w_1 \cdots w_n, X_1, X_2 \mid h),$$

(d) Marketing

$$X_4 = f_4(q, r_1 \cdots r_n, X_3 \mid h), \quad \text{and}$$

(e) Management

$$X_5 = h + f_5(q).$$

where

X_1 = financial costs per unit,

X_2 = procurement costs per unit,

X_3 = production costs per unit,

X_4 = marketing costs per unit,

X_5 = management costs per unit,

q = quantity produced per unit of time,

k = exogenous market factors, e.g., prime interest rate,

w_i, r_i, v_i = variable factors of production, and

h = constant factor.

The last function with factor h reflects the fact that management may be constant or given over large intervals of q, but that some inherent features may exist that differentiate between management of large companies and those of smaller concerns. At any one level of activity in the market structure, these relationships must be integrated by any particular firm. Thus, we can define

$$Z_j = g(X_{1j} \cdots X_{5j})$$

as being the total cost function facing a firm at level j. This function, of course, is a function of several functions; and the optimum scale of operation, given the total function, may bear no resemblance to the scale which optimizes operations of the individual functions as illustrated by Danø [7].

In a nonintegrated industry with several levels of activity in the market structure, the total costs involved in getting the product from producer to consumer (assuming equal output capacities or ranges for all levels) may be represented by the summation of the individual firm functions at the various levels of activity, or

$$Z_t = \sum_j Z_j$$

where

$$Z_t = \text{the total function.}$$

Interfirm integration

When a firm can coordinate the above five categories among various levels of activity more effectively (or profitably) than the market mechanism, there will be an inducement to integrate vertically [4, 24]. Extension of administrative decision by one firm into a new level of activity may offer a superior (more profitable) organizational structure to regular market system, a factor that may arise not only from the administrative capabilities within the firm, but also from the imperfect nature of coordination from or the cost of using the market system [see 6, 22]. Similarly, integration by merger offers a firm one means of bypassing the limitations of current management's skills and knowledge in new areas cited by Penrose [21]. It may also offer a means of obtaining additional financing ability through use of assets of the firm that is integrated.

In such cases, the integration of the above five functions at different levels probably will not be the same as the summation of the total firm functions over different levels of activity. In this case we have

$$Z_t^* = f(X_1^*, X_2^*, X_3^*, X_4^*, X_5^*)$$

where the * superscript indicates an integrated function.

For a firm that utilizes the outputs of other levels of activity as inputs, the question is one of determining whether the change in costs for producing a given output plus the accumulation of profits accruing to other levels of activity offers sufficient return on the investment. Penrose [21, p. 146] notes that

> . . . the profitability of backward integration is measured by its effect on the net revenue of the firm. Hence the opportunity to increase profits by integrating backwards is to be treated in the same way as other productive opportunities of the firm—the additional profit expected must be compared with the expected profit from alternative uses of the resources required.

The above formulation is basically the same as that given graphically by Mighell and Jones [19] in a planning system for firms with vertical combinations.

Risk as a Decision Variable

Evaluating a firm's action solely in terms of maximizing return on investment is not always applicable, as noted earlier. Other restraints may outweigh the potential return of an investment. Penrose [21, p. 147] adds that

> . . . backward integration, like other forms of diversification, is promoted by a desire to avoid the risk of fluctuations and to enhance the security of the firm in the face of a generalized uncertainty. In this latter case, the statement that a reduction in cost is a condition of profitable backward integration is a purely formal one, for 'cost' is reduced only because of an arbitrary, noncalculable, and essentially psychological element attributed to the firm's attitude toward uncertainty.

Seaver [23, p. 1491] is even more emphatic with respect to the relative importance of risk aversion as a motive for integration. He says:

> Frankly, the core of the problem is not production costs, whether farm or plant. . . . There are two aspects of integration, neither of which has received sufficient attention from agricultural economists, that offer an opportunity to "hit the jackpot." The first of these deals with risk and uncertainty associated with the operation of the "free market"; the second with monopoly and market control.

Risk of a short-run nature frequently occurs in agricultural processing industries. Some components of this risk may be internal to the operations of the firm, while other aspects may result from the inadequacies of the market system coordination as presently organized [22]. In many cases, inputs are purchased on the basis of estimates (as in the case of livestock) concerning the quality and quantity with which the raw product will be converted into final product. These estimates are subject to considerable error and may be the source of operating losses to the company [18].

In other instances, risk manifests itself through extreme variations in the quantity of raw product available to producers at given times. This variation can affect processing costs if the firm utilizes large amounts of fixed factors [16]. Dependence on price competition is no guarantee to a processor that his supply will be increased [20].

Reduction in such short run risk either of the internal sort or of the market type can be a strong inducement for some firms to integrate, just as elimination of marketing risk through forward integration is a motivating factor to other firms. The effects of integration on total short-run risk faced by the firm can also alter the profit structure (and thus return on investment) of other levels of activity in the integrated firm, a factor that can be of prime importance in decision making about long-run growth of the firm.

Measuring risk

Many of these risk factors are difficult to define, let alone measure, and perhaps a firm may be able only to establish whether the risk under integration is just "more or less" than that in an open market. However, some risk factors often can be quantified. For example, statistical techniques can be applied to past price and supply trends, or to employee performance, in an attempt to estimate the risk factor under the various market structure alternatives.

If we can measure the risk associated with return on investment as the variance of that return or the variance of a major component of that return (e.g., costs or revenues that can serve as a proxy variable), then we can estimate the change in risk through use of integration. Define

σ_1^2 = variance of return on investment at level of activity 1 (r_1),

σ_2^2 = variance of return on investment at level of activity 2(r_2), and

r_{12} = correlation between r_1 and r_2;

then, combining the two operations,[6]

$$\sigma_{1+2}^2 = \sigma_1^2 + \sigma_2^2 + 2r_{12}\sigma_1\sigma_2$$

where the third term on the right is twice the covariance between r_1 and r_2.

If the two levels of activity are independent with respect to return on investment, the covariance is zero; and the variance of the combined levels is simply the sum of the individual variances. A negative correlation between r_1 and r_2 will result in a combined variance of less than the sum of the individual variances or in a reduction of risk. A positive correlation will mean the combined variance is larger than the sum of the component variances.

The *net* risk of investment in integration, then, would be given by

$$\sigma_{1+2}^2 - \sigma_1^2 = [\sigma_1^2 + \sigma_2^2 + 2r_{12}\sigma_1\sigma_2] - \sigma_1^2 = \sigma_2^2 + 2r_{12}\sigma_1\sigma_2.$$

---

[6] For a discussion of variability in combined farm operations, see Carter and Dean [5].

Stochastic factors

When a firm faces a production function that includes uncertainty (or lack of ability for precise measurement of variables) for quality and/or quantity of output from a given set of inputs, we can define the function as:

$$Q_j = f(v_1 \cdots v_n, e_j)$$

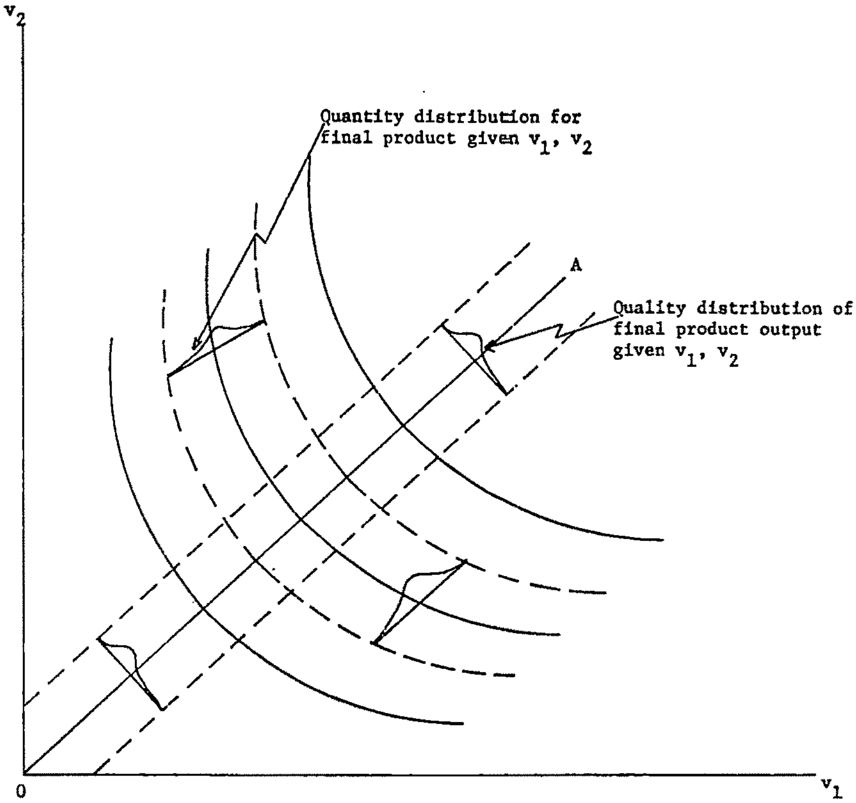
where

Q_j = output of firm at level j,

v_i = factors of production, and

e_j = a stochastic variable with mean and variance (μ, σ^2).

Graphically, this situation is illustrated in Figure 4. Assume the firm uses two inputs to produce one final product. The two inputs, v_1 and v_2, are dif-



v_2
Quantity distribution for final product given v_1, v_2
A
Quality distribution of final product output given v_1, v_2
0
v_1

Figure 4. Isoquants with quality and quantity risk factors for inputs v_1 and v_2

ferent quality forms of the same factor of production; however, in the raw product stage the quality aspect must be estimated either by observation or by sample techniques (such as good and choice grade slaughter cattle). The net result is that, for any combination of v_1 and v_2, the final product Q will not necessarily possess the same quality proportion as indicated by v_1/v_2. A particular ray from the origin, such as OA, indicates a set quality ratio of inputs [7], but the actual quality of final product will have a probability distribution around that ray.

Similarly, the quantity of output indicated by the usual isoquant form may not be totally dependent on v_1 and v_2 but may also have a probability distribution around the isoquant for any particular combination of v_1 and v_2 because of possible spoilage or rejections in the inputs or misestimation on the part of buyers.[7]

Of course, if the inputs can be evaluated with certainty, and the production process itself is not subject to random fluctuations in performance of workers, etc., then the traditional deterministic isoquants become applicable.

The above production relationships may be considered for two particular levels of activity, h and j:

$$Q_j = f(v_i, e_j) \quad \text{and}$$
$$Q_h = f(w_i, e_h)$$

where

w_i=factors of production used in level h.

By integrating backward, for instance, firm j may be faced with a combined production function indicated by:

$$Q_j^* = f(v_i, w_i, e_j^*).$$

If the only change in the functional relationship is in the error term, the advantage of integration at each level can be measured by comparing the means and variances of e_j and e_h with those parameters for the distribution of e_j^*.[8]

Similar risk factors may exist for the other phases of operations within a firm, e.g., finance, procurement, marketing, and management at all different levels of activity in the production-processing-marketing structure.

---

[7] The quantity risk just outlined, however, is different in nature from the shifts in supply of raw products frequently cited as a reason for integration [20]. This latter factor relates to the nature of stability of the flow of raw products during all parts of a given time period, such as one year. Random divergences from such a pattern will, of course, alter the nature of average unit costs facing the firm for that time period, with the net effect that the average long-run cost curve shifts upward and may be distorted from the equilibrium position. Conceptually, the risk of stable supplies can be incorporated into the above framework.

[8] It is possible that the covariance between the two levels of activity will act so as to *apparently* reduce the variance of only one component level, but considering the variances of the components separately after integration can be misleading.

Depending on the nature of the firm's aversion to risk (utility function), a reduction in the variance of the error factor, even without a change in its mean, may be sufficient to warrant integration. By narrowing the distribution around its mean through integration, the firm may effectively cut its "probability" of going broke if severe fluctuations in any of the functional relationships can be fatal financially. This type of return cannot be put into a usual rate of return on investment figure.

However, depending upon the nature of the frequency distribution of the variable, changing the variance or risk may also alter the mean, a factor that in turn can affect the profit picture and thus return on investment. For such a change to be successful, the integration generally must be associated with a conscious management strategy in the use or coordination of the various levels of activity.

Price risk

If the risk that exists in the price function facing the firm is such that in a purely competitive market

$$P_j = K + e_j,$$

where K is a constant and e_j again is the stochastic term, then the profit function at any one level of activity may be considered

$$\begin{aligned}\pi_j &= P_jQ_j - TC_j \\ &= (K + e_j)f(v_i, e_j) - g(Q_j),\end{aligned}$$

where

$g(Q_j)$ = the total cost function for the firm.

For this particular level of activity, integration may not alter the price uncertainty; but the production function may be altered with a change in the error factor; and the cost function itself may change, thus giving a different profit function.

The change in profits for activity level j becomes part of the measure of return on the investment to level j from integration and must be included in the decision of whether to integrate along with the regular measures of return (cash flow) on investment.

Conclusions

Vertical integration, like most types of firm growth, is more complex with respect to underlying causes and effects than situations represented in the maximization of a single variable such as profits or return on investment. The use of lexicographic or multidimensional utility functions offers a more satisfactory method to analyze and explain firm integration. The model developed above postulates two variables in a firm's utility function that might logically apply to integration: (1) maximization of return on investment and (2) reduction in short-run risk. While each variable will assume different importance from firm to firm, risk reduction undoubtedly plays an important part in decisions to integrate.

Thus, a firm must consider more than just return on investment resulting from the profits of the new level to be integrated; it must also know the change in profits of its current operation after integration. In addition, the firm must analyze the risk associated with the quantity and quality of the supply of inputs (or outputs) before and after integration. Such risk may be focused on only parts of the total operation, such as the internal operation of the firm or the external market mechanism.

Decision making must consider jointly the change in the distribution of these risk factors after integration with the return on investment (or other utility variable).[9] And the two variables may not be independent themselves. Thus, for example, changing the nature of the distribution of return on investment may result in a change in the expected return, depending upon the type of distribution. These changes must also be associated with some specific management or administration plan or strategy in the use of the integrated components.

An Analysis of Daily Fluctuations in the Hog Economy*

RAYMOND M. LEUTHOLD

A recursive model is developed to identify and evaluate the major factors affecting daily fluctuations in hog prices and quantities supplied. Using two years of data, packer price bids for slaughter hogs are found to depend upon lagged wholesale prices, present and lagged quantities of hogs marketed, and the day of the week. Producer's daily marketing responses depend upon lagged price, day of the week, and season of the year. Elasticity of supply is very high, ranging from 8 to 10. Daily ex post forecasts of price and quantity supplied are made for a one year period and indicate that variations in the regression coefficients from month to month, resulting from updating of the model, provide virtually no improvement of the forecasts over using an initial set of coefficients. The developed model predicts daily price fluctuations more accurately than a naive model tested.

PAST research on hog marketing has been confined largely to investigations of recurrent hog price cycles, trends, and patterns. Relatively few investigators have analyzed short-run, or daily, price variations. This research void may have stemmed from the difficulty in obtaining and handling daily time series data. High speed electronic computers now make it feasible to process and store the large amount of information needed for the analysis of daily data.

Much remains to be learned about the day-to-day hog market and its response to changes in various economic variables. More information about demand and supply functions is needed for improved policy formulation and decision making by market participants. The study reported in this article was designed to identify the major factors affecting daily price and quantity movements and to provide knowledge about the relevant economic behavioral relationships within hog marketing. A demand and supply model is formulated and estimated and future daily price and quantity fluctuations are predicted by using the results of the estimated model.

The price and quantity supplied patterns examined are based on data for the public terminal hog markets located in Chicago, Indianapolis, Kansas City, Omaha, South St. Joseph, East St. Louis, South St. Paul, and Sioux City, the eight largest hog markets in the United States. These markets represent the major concentration points of buyers and sellers and act as a guide in the pricing of hogs in other markets [8; 9, p. 11].

Economic Model

Demand for live hogs

The quantity of live hogs demanded is a derived demand, as hogs are the major raw material in producing pork. Normally, using classical economic theory and assuming profit maximization, the quantity of an input demanded depends upon its price, the price of other inputs, and the price of the product [1, 5]. However, at the major hog markets the supply of hogs generally arrives before the markets open, and the markets are then cleared each day. The daily quantity demanded by the buyers on any particular day is predetermined by the quantity available, and price is the adjusting mechanism.[1] Therefore, the demand function expresses input price as a function of quantity, product price, plus other variables such as storage and day of the week.

In choosing the variable to represent the price of the product (wholesale pork cuts), it was recognized that when packers bid on live hogs during day t, they must have expectations of wholesale prices for days $t+5$ to $t+7$ (the time needed for processing and shipping the cuts). Their expectation models are probably relatively complex. For simplicity, I used the most recent wholesale price information, the previous day's price $(t-1)$, as a proxy variable to represent these expectations. As this price increases, packer price bids for slaughter hogs will likely increase the next day because of the expectation of higher wholesale prices in the future.

It was also hypothesized that the price packers offer for hogs depends in part upon the number of hogs they have on hand and the amount of pork in cold storage. Eleven models were tested, using various combinations of lagged terminal and interior market quantities [7] to find a proxy to represent these storage items.[2] Selecting the model that gave the largest coefficient of multiple determination, the most appropriate proxy was found to be the aggregate quantity supplied by the eight terminal markets for each of the previous two days. Thus, these two quantities were included in the demand function to represent storage under the assumption that, as these quantities increase, subsequent packer price bids will decrease, and conversely.

Additional factors cause the packers to vary their price bids on hogs according to the day of the week. One is the packers' attempt to fill a specific number of hours per week in their labor contract, requiring them to increase their price bids at the beginning of the week so that they can purchase large quantities of hogs and be assured of fulfilling the contracts and maintaining a uniform rate of slaughter throughout the week. This and other associated influences are represented by dummy variables that shift the demand function according to the day of the week.

---

[1] Of course, quantity varies from day to day and from week to week. However, trading at the terminal hog markets is conducted in such a fashion that sellers have virtually no chance to respond to the price within the day. This trading characteristic is not necessarily true for country buyers, dealers, and auction markets, which are not analyzed in this study.

[2] Since daily data on cold storage and hogs on hand are not readily available, previous quantities supplied are used as approximations of storage.

Finally, as mentioned above, quantity delivered each day was included in the demand function as an exogenous variable. All variables are defined more specifically below.

Supply of slaughter hogs

The supply function for slaughter hogs in this study is derived from the classical equilibrium theory of the firm. Hog producers are assumed to operate in a purely competitive market and attempt to maximize profits. One shortcoming of the theory, however, is that it fails to distinguish between marketing (short-run) decisions and production (long-run) decisions. Since our concern is with the short run, the classical theory is modified somewhat to exclude past production costs and most other long-run influences.

The quantity of hogs supplied at the eight terminal markets arrives before the markets open and there is virtually no opportunity for producers to adjust their shipments in response to price within the day at these same markets. Therefore, it was assumed that producers operate on the basis of an expected price for their hogs, which is based on information generated prior to the marketing day. Eleven models, using various weighted and simple moving average schemes of past prices to represent this expectation, were tested. The model that produces the largest coefficient of multiple determination is one in which the expected price is the same as the previous market day's price, after adjusting for the day of the week [7]. Thus, price lagged one period was included as an explanatory variable in the supply function, with the expectation that as this price increases, producer marketing responses will increase the next day, and conversely.

Previous studies have shown the day of the week to be an important influence on quantity supplied [2, 10]. Farmers tend to market more hogs at the beginning of the week, especially Monday, because they expect higher prices then and they have more time on weekends to prepare their livestock for market. This phenomenon is represented by dummy variables, which shift the supply function according to the day of the week.

Hog farrowing follows seasonal patterns and this subsequently affects the number of hogs to be marketed at later times, after the necessary feeding period. A variable that shifts the supply function according to this seasonal adjustment was included as an explanatory variable.

The Statistical Model

The demand and supply functions, as specified above, define a recursive model of the cobweb type, where first the quantity supplied is determined through the supply function and then this quantity is sold in the market at a price determined through the demand function. That is, the quantity demanded is a predetermined variable and the error terms of the demand and supply functions are assumed to be independent. Thus, with the normal assumptions on stochastic regressors, ordinary least squares regression will yield consistent and asymptotically unbiased estimators of the parameters of each function [4, pp. 269–271, 279–280, 354–355; 6, pp. 75–77].

The double-log functional form was used for both the demand and supply functions based on the assumption that buyers and producers respond to percentage (or relative) changes in the market. Because of the interest in explaining daily changes rather than absolute amounts, plus the need to reduce autocorrelation in the residuals and multicollinearity in the original values, the economic data were transformed into first differences of logarithms.[3] However, the dummy variables were not transformed into first differences and were specified to act as shifters of the functions. The entire statistical model can be represented as follows:

$$\begin{aligned}\text{Demand: } \Delta \log P_t = {} & \beta_{11}\Delta \log Wh_{t-1} + \beta_{12}\Delta \log Q_t \\ & + \beta_{13}\Delta \log Q_{t-1} + \beta_{14}\Delta \log Q_{t-2} \\ & + \beta_{15} \log M + \beta_{16} \log T + \beta_{17} \log W \\ & + \beta_{18} \log F + u_{1(t)}\end{aligned}$$

$$\begin{aligned}\text{Supply: } \Delta \log Q_t = {} & \beta_{21}\Delta \log P_{t-1} + \beta_{22} \log M + \beta_{23} \log T \\ & + \beta_{24} \log W + \beta_{25} \log F + \beta_{26} \log S + u_{2(t)}\end{aligned}$$

where:

P_t = average price in dollars per hundredweight of all barrows and gilts sold at the eight markets[4] in day t;

P_{t-1} = representation for expected price by producers, defined the same as P_t but for the previous day;

Q_t = total number of head of barrows and gilts sold at the eight markets[5] in day t;

Q_{t-1}, Q_{t-2} = "proxy" representations for storage, defined the same as Q_t but indicating quantity on previous days;

Wh_{t-1} = representation of the price of the product, measured as a weighted average (based on a percent of total live animal weight) of the prices in dollars per hundredweight of major wholesale pork cuts, Chicago;

---

[3] All logarithms are natural logarithms.

[4] The average price per hundredweight at any one market is the total cost of all barrows and gilts in a day, times one hundred, divided by the total weight of all the animals. The average price for the eight markets is a simple average of the separate market averages.

[5] The effect of weight on price cancelled out when the eight markets were aggregated.

$$M\begin{cases}=2.71828\ldots \text{ if Monday}\\ =1.0000 \text{ otherwise;}\end{cases}$$

$$T\begin{cases}=2.71828\ldots \text{ if Tuesday}\\ =1.0000 \text{ otherwise;}\end{cases}$$

$$W\begin{cases}=2.71828\ldots \text{ if Wednesday}\\ =1.0000 \text{ otherwise;}\end{cases}$$

$$F\begin{cases}=2.71828\ldots \text{ if Friday}\\ =1.0000 \text{ otherwise;}^{6}\end{cases}$$

$$S\begin{cases}=2.71828\ldots \text{ if March, April, August, September, October,}\\ \quad\text{November}\\ =1.0000 \text{ otherwise;}^{7}\end{cases}$$

t = time in days;

Δ represents first differences, such that $\Delta \log Q_t = \log Q_t - \log Q_{t-1}$, and $\Delta \log Q_{t-1} = \log Q_{t-1} - \log Q_{t-2}$, etc.

Procedure and Results

Two years of data, 1964 and 1965, or approximately 500 observations, were available for estimation.[8] In order to observe how the coefficients change over time, the demand and supply equations were estimated over 14 alternative time periods. The procedure in each estimation was to use a time series of 12 months, or about 250 observations, so that the coefficients could be compared over several time series of similar length. The equations were first estimated using the data for all of 1964; then, with data from February 1964 through January 1965, from March 1964 through February 1965, and so on. This pattern of dropping one month in 1964 and adding the next month in 1965, always maintaining a time series of 12 months, was followed to the last possible combination, using the data for all of 1965. Finally, the equations were estimated using the full two years of data, making a total of 14 combinations. These coefficients were then examined to determine how hog marketing and pricing patterns changed over time. The

---

[6] Dummy variables cannot be specified for all five days of the week, as this creates a linear combination in the columns of the raw moment matrix and makes the matrix singular; so Thursday was chosen as a base. None of the eight markets is open on Saturday.

[7] The year was divided into two seasonal groups to reflect farrowing patterns. The six months listed represent those months in which quantity supplied is generally greater than in the previous month. In the other six months, quantity supplied is usually less than the previous month.

[8] The price and quantity data were obtained from records compiled by USDA Market News Reporters located at each of the eight markets.

data were added and dropped in monthly groups (rather than weekly or daily) so that the results could be conveniently reported in this article.

Demand function estimates

The results of the estimated demand equation are given in Table 1. In the first row of the table, the signs of the coefficients of the wholesale price and three quantity variables are consistent with expectations. These coefficients approximate percentage responses, so the first quantity coefficient implies that a one percent increase in the quantity of hogs in time t results in about a 0.05 percent decrease in the price of hogs in time t. Similarly, the two lagged quantity coefficients indicate that a one percent increase in quantity in time $t-1$ results in a 0.04 percent decrease in price in time t, while a one percent increase in quantity in time $t-2$ results in about a 0.02 percent decrease in price in time t. An alternative interpretation of these three coefficients is that a one percent increase in quantity in time t results in approximately a 0.05 percent decrease in price in time t, a 0.04 percent decrease in price in time $t+1$, and a 0.02 percent decrease in price in time $t+2$. These coefficients indicate that packers adjust their price bids not only to present day quantities, but also to quantities for the previous two days, which are a proxy for storage volume. The magnitudes of these coefficients are very small, but consistent with the data—quantity usually fluctuates from 50 to more than 100 percent daily, whereas price generally fluctuates only one to three percent daily.

The wholesale variable coefficient implies that a one percent increase in the wholesale price in time $t-1$ results approximately in a 0.35 percent increase in the price of hogs in time t. This finding indicates that changes in the wholesale market are important in explaining price changes in the live hog market, and the positive sign provides information on the relationship between wholesale prices one day and the resulting packer decisions concerning their live hog price bids the next day.

The dummy variables merely cause the demand function to shift according to the day of the week. Combining the coefficients with the constant term gives some indication of the relative size and direction of the price changes between days, other things equal. Monday has the largest average percentage price change relative to the average of all changes, and the positive sign indicates that price increases on Monday relative to the price the previous Friday. Prices generally also increase slightly on Tuesday, but they decrease the remainder of the week, the largest decrease occurring on Friday. These reactions by packers throughout the week are as expected; they make higher bids at the beginning of the week to assure themselves of enough hogs for slaughter to fulfill their labor contracts and then make lower bids at the end of the week so as to keep storage over the weekend to a minimum.

In the remainder of Table 1, the coefficients for all the variables, except Wednesday, maintain their respective signs throughout all 14 estimations. However, there is no discernible pattern of variation in the magnitudes of the coefficients over time, as some get larger in absolute size while others get smaller. The importance of this variation in coefficients over time will be more easily judged later when price predictions are made.

The coefficient of multiple determination for the demand function ranges from a low of .4932 to a high of .5710, with the two extremes resulting from estimations that have nine months of data in common. These coefficients are rather low, not an unusual outcome when using first differences [3]. Also, some variables undoubtedly have an influence in short-run time periods but are not measurable on a daily basis.

Because of the large sample size of each estimation, the Durbin-Watson (*d*) statistic can only approximate a test for the presence of autocorrelation of the residuals. Using the computed statistic of 100 observations as a guideline, any *d* statistic below 1.50 would probably indicate that positive autocorrelation is present. This outcome occurs in four of the 14 estimations.

Supply function estimates

The supply function results, estimated for the same 14 time periods described previously, are given in Table 2. In the first row of the table, the coefficient for lagged price is 8.2771, which is of expected sign. This price elasticity is rather high, but is in keeping with the size of the daily fluctuations and is consistent with Stover's [11] elasticity estimates for daily prices, published in 1932, which range from 4.4 to 12.0. Presumably, hog producers are very responsive to the previous day's price change in determining the quantity of hogs to be marketed, suggesting a potentially volatile market.

Coefficients of the dummy variables for days of the week indicate that, on the average, quantity supplied increases on Monday relative to the previous Friday and then generally declines the remainder of the week. This is as expected when considering the results of earlier studies [2, 10] and packer pricing habits throughout the week. The positive sign of the coefficient for the season dummy variable is also as expected, since the variable is designed to distinguish between months in which the quantity supplied either increases or decreases relative to the previous month.

In the remainder of Table 2, only the constant term changes sign over the 14 different time periods. The Tuesday variable coefficients become less significant as more 1965 data are included in the estimation, indicating some changes in daily marketing habits through the year. Also, the season coefficients become less significant with more 1965 data, probably because some of the months for 1965 do not fit the specification of the variable and their change is in the "wrong" direction.

** Significant at the 95 percent level.
*** Significant at the 90 percent level.

The coefficient of multiple determination for the supply function varies from .5916 to .7209. Again the Durbin-Watson (*d*) statistic can only be used as an approximation, but any *d* statistic larger than 2.45 probably indicates the presence of negative autocorrelation.

Daily Predictions

To appraise the model's overall worth, its predictive power apart from its explanatory power was tested. Predictions of quantity supplied and price were made one successive day at a time for 1965. The procedure used is known as ex post forecasting, in which the known values of the independent variables are inserted into the proper function to obtain an estimate of the dependent variable, which is then compared with the observed value of the dependent variable for that particular day.

Two methods of evaluating the accuracy of the forecasts were used: (1) to measure the percent of correctly anticipated directional changes of the dependent variable out of a given number of predictions; (2) to compute the deviation of the predicted from the actual value and then to represent this deviation (error) both as a percent of the actual value and as Theil's inequality coefficient.[9] Since there are nearly 250 observations for which price and quantity are predicted, these evaluation results have been summed and averaged over given time periods for the purpose of presentation.

Supply predictions

The quantity of live hogs supplied for the aggregated eight markets has been forecasted by two methods for each market day of 1965. In one set of forecasts, referred to as Model 364, only the coefficients of the January–December 1964 estimation are used.

In the other set of forecasts, Model SDC, a different set of coefficients is used for each month predicted. The set of coefficients used for any given month corresponds to the equation estimated from the previous 12 months' data. For example, predictions for March 1965 are based on the March 1964–February 1965 coefficients, those for April 1965 are based on April 1964–March 1965 coefficients, and so on.

The inequality coefficient, average absolute percentage error, and percent of correct directional changes forecasted, summarized by months for

---

[9] Theil's inequality coefficient is:

$$U = \sqrt{\frac{1}{n} \sum (P_i - A_i)^2} \Big/ \sqrt{\frac{1}{n} \sum (A_i^2)}$$

where *P* and *A*, representing predicted and actual observations, respectively, are expressed in terms of changes [12]. The smaller the coefficient *U*, the more accurate are the forecasts. In contrast to other inequality coefficients Theil has designed, this one can be larger than 1.

both models, are given in Table 3. The last row of the table shows weighted averages of the 12 months of the corresponding column.

Both models have an average absolute percentage error for 1965 of slightly over 14 percent and nearly identical inequality coefficients near .66. Each model correctly predicts the direction of change more than 80 percent of the time. Predictions of direction are most accurate for January, where all the changes are predicted correctly, and December, where 16 of the 17 changes are predicted correctly. A comparison of the predicted supply corresponding to Model S64 with the actual supply for 1965 can be seen in Figure 1, which illustrates the large daily quantity fluctuations.

Table 3. Summary by months of supply prediction errors for each market day of 1965 for aggregated supply of eight terminal markets

Month	Model S64			Model SDC

Year, 1965[a]	.6548	14.66	84.3	.6609	14.63	82.7

[a] Weighted average of 12 months' data.

There is very little difference in the forecasting accuracy of the two models, S64 and SDC. Not only are the inequality coefficients nearly identical for the entire year; they are also similar for each respective month. The average absolute percentage error for the year differs between the two models by only 0.03 percent, an average difference in prediction of only nine head a day. The percentage of correct directional changes predicted is nearly identical for the two models also. The important implication is that, for the period under investigation, forecasting accuracy does not appear to improve significantly as a result of applying new coefficients obtained with more recent data. Thus, for this time period, it does not seem necessary to reestimate the supply function month by month, since the forecasts from

the first set of coefficients are not improved upon. This implies that the marketing structure of hogs at the terminal markets did not undergo any large changes over the two-year period, despite the fact that the total supply in 1965 was less than normal, causing prices to get abnormally high later in the year.[10] However, in applying this model into the future, it may be necessary to update it frequently since market behavior could change abruptly.

Price predictions

Price for the aggregated eight markets also is predicted by two methods for each market day of 1965: Model P64 uses only the January–December 1964 coefficients; Model PDC uses different coefficients for each month. Monthly summaries of the results are given in Table 4.

Table 4. Summary by months of price prediction errors for the average price of eight terminals for each market day of 1965

Month	Model P64			Model PDC			Model PN
	Theil's inequality coefficient	Average absolute percentage error	Percentage correct direction	Theil's inequality coefficient	Average absolute percentage error	Percentage correct direction	Average absolute percentage error
January	.5810	.69	68.4	.5810	.69	68.4	1.03
February	.7036	.75	55.0	.7036	.75	60.0	.90

December	.8147	1.87	64.7	.7659	1.74	70.6	2.33
Year, 1965[a]	.7978	.81	69.1	.7803	.77	72.3	1.05

[a] Weighted average of 12 months' data.

The last row of the table is a weighted average of the months of the corresponding column. Both models forecast with average absolute percentage errors of less than one percent and inequality coefficients of near .80; both correctly predict the direction of change about 70 percent of the time.

Again, there is little difference in the forecasting accuracy of the two models. Model PDC, which uses new coefficients each month, predicts slightly more accurately than Model P64, but not enough to warrant reestimating the demand function each month. This supports the previous conclusion that the hog marketing structure at terminal markets underwent little change during the period of analysis.

---

[10] These supply forecasts in aggregate form were not compared with any alternative models, but the supply forecasts for individual markets were compared with USDA daily predictions in [7].

Figure 2, which compares the predicted price of Model P64 and the actual price for 1965, illustrates the accuracy of the predictions. Of course, since each prediction is stated as a change from the previous day's actual price, it is not expected that the predictions would wander much from the actual prices.

As a further test of the predictive capacity of the model developed, price predictions were compared with those of a naive model, PN, in which it was assumed that the price in day t would be the same as the price in day $t-1$ (as in the producer's price expectation model assumed in the supply function). Because the inequality coefficient of Model PN is equal to 1.0, only the average absolute percentage error is summarized in Table 4.

Both Models P64 and PDC forecast more accurately on the average than Model PN, which predicts more accurately only in July and September. In comparing actual average absolute prediction errors, Models P64 and PDC show an improvement in predictive accuracy of 22 and 26 percent, respectively, over Model PN. Thus, the model developed here predicts price more accurately than the next best alternative price forecasting model presently known.

Conclusions and Implications

This analysis of the daily live hog marketing process provides some interesting results and information about the hog economy and its participants. First, the price offered by buyers for slaughter hogs responds relatively very little to daily changes in quantity. However, the quantity supplied in any one day influences price for three consecutive marketing days, suggesting that buyers might take account of the market quantities over a period of days rather than a single day. This implies that storage plays an important role in buyers' daily decision making. In addition, wholesale prices of pork cuts from the previous day, in part reflecting consumer desires, provide signals to the packer about future wholesale prices, causing him to adjust his price bids for slaughter hogs very quickly. Finally, on the demand side, the day of the week influences the buyers' price bids, these being higher at the beginning of the week and lower at the end of the week. This shows that the buyer not only reacts to changes in quantity and product price, but also apparently to internal management decisions, such as labor contracts, which influence the packer's daily operation schedules.

On the supply side, hog producers appear to be extremely responsive to short-run changes in price. A one percent change in price in a given day

results in quantity supplied changes the next day of 8 to 10 percent. In addition, the day of the week is important in producer marketing decisions, with marketings highest at the beginning of the week and becoming smaller towards the end of the week. Such a response probably reflects not only traditional marketing habits of producers, but also their reaction to the lower prices offered by packers after the first of the week. Thus, the demand and supply functions indicate that decision making by producers and buyers of slaughter hogs is interrelated through the week as both anticipate particular actions by the other on specific days and both adjust to such exogeneous factors as storage requirements and wholesale price fluctuations.

The small price responses and large quantity responses could have important policy implications, as these may lead to considerable fluctuation of farm incomes and packer profits. The fluctuations in turn may increase uncertainty and inefficiency, creating unnecessary costs in the areas of planning, financing, and risk aversion, which then may call for public and/or private action to reduce such costs. Possible action could include policies to aid packers in controlling stocks or inventories, reducing packer uncertainty and, hence, helping to reduce price and quantity fluctuations. A reduction in quantity fluctuations alone would reduce the costs of inefficiencies not only for packers, but also for stockyard companies and trucking firms who must employ sufficient rescurces to handle the volume of peak days, thereby creating ideal resources on other days. A reduction in price fluctuations should reduce producer uncertainties and related costs.

The predictions made in this analysis indicate that the variations in the coefficients over time had little effect on the forecasts. That is, the appearance of new data in the model did not seem to improve the accuracy of forecasts significantly, implying that if market participants use such a model, re-estimating it frequently over short time periods may be an unnecessary expense, except when market behavior is changing rapidly. This also indicates that the structure of daily marketing within the hog industry at the terminal markets changed very little during the two-year period analyzed. However, before extending these conclusions to either the interior markets or today's terminal market activities, further analysis and updating are probably necessary. Nevertheless, the results of this study undoubtedly can aid present market decision makers.

Finally, this study suggests that similar techniques might be used to analyze short-run fluctuations in other commodities, either jointly or individually. This would aid in the large-scale tasks of providing information and forming policies.

Factors Associated with Variation in the Aggregate Average Yield of New Zealand Wheat (1918–1967)*

JOHN W. B. GUISE

An apparently successful test of a "step function" hypothesis about the effect of technological change in the agricultural sector is reported. The effects of weather and other factors on wheat yields are also analyzed. A notable feature of the research was the lack of significance of an ordinary time trend variable, used as a surrogate for technological change, when a detailed specification of these factors was developed. Overall, 98.6 percent of the variance of the dependent variable in the sample was accounted for by a regression relationship involving seven weather and four nonweather variables, only one of which related to technological change. The potential value of this relationship for forecasting crop yield is indicated by the fact that the standard error of forecast was substantially less than the standard deviation of errors for the present system of preharvest yield estimation.

STUDIES of the effect of weather conditions on crop yields have been of continuing interest to agricultural scientists for many years. Agricultural economists have become interested in this field of study only in recent years, with the development of attempts to separate the effects of weather and technological change in explaining yield variation [2, 11, 18, 29]. This specialized interest has arisen because of the relevance of technological change in agriculture to economic growth and development generally [12, 13, 16, 23]. An approach that has been adopted in a number of cases to isolate the technological factor [11, 17, 20] is to regress crop yield data on weather variables and a time trend, the time trend being taken as a surrogate for technological change.

Commenting on this approach, Scott [24, p. 657] states that "it is doubtful that development of technology or its subsequent application follows a continuous function. From a statistical stand-point, a time variable may reduce the variance more than can rightfully be accounted for by changes in technology." More specifically, but in similar vein, Shaw [25] argued that technological change in agriculture tends to occur in the form of shifts over a relatively short time period in the general level of yields and that the new levels attained remain constant, apart from the random effects of weather, until another burst of technological change occurs.

If technological change in the agricultural sector does tend to follow an

irregular step function as Shaw suggests, then, although a time trend may "explain" a high proportion of yield variation over time, it will in fact misspecify the real structure of technological change. This article reports a test of Shaw's "step function" hypothesis about the effect of technological change in the agricultural sector and explores the relevance of certain other factors in explaining wheat yield variation in New Zealand over a fifty-year period.

The Wheat Yield Model

The basic approach to specification in this model is via the production function. It is assumed that wheat yield in any one season, from a particular unit of land, is a function of the inputs of labor and capital in the form of cultivation and harvesting operations, of the basic fertility of the land, of the input of fertilizer, of the incidence of disease and the effects of weather. Aggregating over all land units used for wheat and then averaging, aggregate average yield in any one season will be a function of suitable indices of average inputs of labor, capital, and fertilizer, together with other indices of average land fertility, the incidence of disease, and the effects of weather.

Over an extended time horizon, the level of crop production technology applicable in most pairs of consecutive years is assumed to be comparable, but between certain years, shifts in technology that raise the level of output obtainable from a given level of inputs are assumed to occur. Only technological change occurring in the agricultural sector of the economy is assumed to effect such shifts. Technological change in other sectors of the economy is not treated explicitly, since its effects are reflected in changes over time in the factor and product price ratios relevant to the agricultural sector and hence in the optimum levels of non-farm inputs used in production [14, p. 846].

To handle agricultural technology in the model adopted for the present study, a distinction is made between variables that are regarded as shifters of the intercept of the production surface on the yield axis and variables that are regarded as normal factors of production generating the surface. While several other factors are also treated as shift variables, a specification that allows technological change to effect discrete shifts in output only at certain times differs rather markedly from that usually assumed [1, 11, 22].

A Cobb-Douglas type structure is specified for the normal factors of production in the model but the shift variables are specified in exponential form, thus giving a hybrid character to the model:

$$Y_t = \beta_0 \cdot \beta_1{}^{X}1t \cdots \beta_j{}^{X}jt \cdot X_{kt}{}^{\beta_k} \cdots X_{nt}{}^{\beta_n} \cdot u_t \tag{1}$$

where

Y_t = aggregate average yield of wheat per acre in season t;

β_i = a parameter of the production function where $i = 0, 1, \cdots, n$;

X_{it} = a shift variable affecting the level of output in season t for $i=1, \cdots, j$; and an index of the level of input i in season t for $i=k, \cdots, n$;

u_t = an unobserved stochastic variable assumed to have a log-normal distribution.

To put empirical content into this theoretical model, it is necessary to specify suitable indices for each of the factors considered and to identify the major technological innovations affecting wheat yields.

Specification of Indices of the Variables

A number of conceptual problems relating to the aggregation of micro-relationships into a single macro relationship arise when one attempts to specify indices of inputs [9]. These difficulties and their anticipated effects on the relationships estimated have not been analyzed systematically.

Even for the index of output, average yield, it was apparent that the geometric mean of per acre yields in each year was the appropriate concept to use, rather than the arithmetic mean. Since this was not available, it was necessary to fall back on the assumption that the percentage bias in the index was constant over time and, hence, that its effect would appear only in the regression constant.

Labor and capital inputs

Over the time period considered there has been a substantial shift in the proportions of labor and capital employed as inputs in the form of cultivation, sowing, and weed control operations. However, the environment developed for crop growth has remained substantially the same despite these changes, and hence it may be inferred that they have had a negligible effect on crop yields. For this reason, changes over time in the proportions of capital and labor employed in carrying out these operations were assumed to be compensating, so that their combined effect on yield was approximately constant over the years.

Since labor and capital inputs are notoriously difficult to quantify accurately, this assumption, which provides a suitable representation of the empirical evidence, was most convenient, as it permitted these factors to be included implicitly in the constant and error term of the production function. It is possible however that an important area of technological change has thereby been neglected, as quality changes in both input factors have probably brought about a reduction in the overall commitment of real resources required to prepare the crop environment in recent years. Nevertheless, *in terms of input units of constant quality*, however measured, no such reduction in commitment of real resources is assumed to have occurred.

Labor and capital inputs employed in harvesting operations were assumed to be relevant to the yield relationship only if there had been a change in the relative efficiency of harvesting operations over time, since the demand for these inputs depends upon the yield achieved. Despite the changes in havesting technology, the ratio of potential pre-harvest yield to actual harvested yield, was considered to have been almost constant over the seasons involved.[1]

Fertilizer inputs

Phosphatic fertilizer was the only fertilizer input of any importance for New Zealand wheat production during the fifty-year period under consideration, but a consistent physical measure of this input could not be obtained. Data on total fertilizer usage for all purposes was not available for the earlier years, let alone data relating to fertilizer usage on wheat, so an indirect approach to the specification of fertilizer input was necessary.

In considering the economic factors involved in farmers' decision-making about fertilizer inputs, it seemed logical to conclude that fertilizer usage would increase as the expected price of wheat in the new season increased, relative to the price of fertilizer at time of sowing. The work of Griliches [10] suggested that such a price ratio variable could be regarded as being independent of technological change in the *agricultural* sector of the economy.[2]

The land input

Changes in the average quality of the land used for wheat production in New Zealand may have occurred in three main ways, only one of which involved technological change. First, because wheat production occurs on a number of different soil types, which vary in basic fertility and water holding capacity, a change may occur in average yield when the proportions of the various soil types used to grow the crop are varied. Only one major shift in the proportions of different soil types used to produce the New Zealand wheat crop occurred during the period 1918–1967. This came about between the 1947–48 and 1948–49 seasons as a result of the coincidence of a number of economic factors [15, pp. 55–56]. The simplest way to incorporate this change in the model was to specify a dummy variable as one of the shift factors.

Second, a change in average yield may occur when the size of the wheat crop is varied, even though the proportions of different soil types are held constant. On all soil types, theory would suggest that marginal wheat acres would be less fertile than intra-marginal acres, since they would represent second, third, or fourth crops, depending on land quality, in a rotational system with pastures and other less demanding crops. Wheat acreage harvested was taken as the logical index of this aspect of land fertility, since in the New Zealand context this statistic was equivalent to wheat acreage planted with intention to harvest, which was not available.

---

[1] The problem of bias in actual average crop yield reported compared with potential pre-harvest yield, which may arise in most wheat growing regions through crop abandonment in drought seasons, is of little importance in New Zealand because of the relatively favorable climatic conditions experienced, even in so-called "bad" seasons.

[2] For U.S. agriculture as a whole, Griliches found that it was possible to explain almost all the variation in fertilizer consumption over the period 1911–56 on the basis of changing relative prices and the induced learning process these changes brought about.

Third, over the time span considered, an enormous investment in land improvement occurred, and this has changed substantially the average level of fertility of all land used for wheat. The major factor affecting soil fertility was the post-war program of land improvement by the use of lime, fertilizer, certified pasture seeds, chemicals for weed and pest control and intelligent stock management. A feature of this land improvement program was that it was directed primarily toward increasing livestock carrying capacity on pastures, with the improvement in soil fertility for wheat growing being regarded as incidental. The technological changes involved could therefore be regarded as having occurred outside the wheat-growing sector of the economy.

The average level of livestock carrying capacity, per acre devoted to livestock in the major wheat growing areas, was chosen as an appropriate variable to measure the impact of this complex of factors on temporal changes in soil fertility. A series, the detailed derivation of which is given elsewhere [15, p. 109], was developed to measure livestock carrying capacity, using basic data from a number of sources. As with the first aspect of land fertility discussed, it seemed appropriate to specify this variable as a shift factor.

The incidence of disease

A certain incidence of disease may be expected in all seasons, and minor variations in this incidence will contribute to the random error of any regression relationship explaining temporal wheat yield variation.

During the fifty-year period under consideration, there were certain seasons that were unaffected by drought, but when very large reductions in wheat yield occurred nevertheless. Smith and Wright [27, p. 60] state that barley yellow dwarf virus was the most likely cause of these yield reductions.

A dummy shift variable representing virus incidence, which took the value unity in six seasons and zero in all other seasons, was introduced into the regression model to account for this behavior of the dependent variable. The specification of this dummy variable implies that the same percentage reduction in yield was brought about by virus attack in each of these six seasons and that in other seasons the effect of disease factors was so small that it could be neglected.

Weather Factors and Technological Change

During a recent controversy in this journal, Shaw [26] put forward the opinion that "we are unable to specify satisfactorily the relationship between (crop) output and meteorological variables." In replying to this attack on his earlier article [5], Doll [6] put forward his own viewpoint, "that specification, while perhaps not simple, is possible, and should not be abandoned without trial." While not wishing to participate in the original controversy, this author finds himself in agreement with the quoted viewpoint of Doll.

The relationship between crop output and meteorological variables is extremely complex, but no more so than many macro-economic relationships. Despite their complexity, econometricians attempt to estimate macro-economic relationships, using relatively simple functions as approximations to the underlying complex functional relationships of reality, and there seems to be no good reason for rejecting this approach to crop: weather relationships.[3]

Climatic factors affecting New Zealand wheat yields

In 1948 Tauheed [30] made a detailed study of the effect of weather on wheat yields in individual counties scattered throughout the important wheat growing areas of the South Island. Because of the differences in objectives, his work was of only limited usefulness for this study, apart from the rationale it provided for limiting the examination of weather to rainfall and temperature elements. Tauheed examined the importance of a large number of meteorological variables in explaining wheat yield variation and was able to demonstrate that the existing variation in most facets of weather, other than rainfall and air temperature, was not significantly related to wheat yield variation.

Eight variables based on these two facets of weather were specified in the present model. Three of these represented rainfalls in October, November, and December, when soil moisture is normally a limiting factor for plant growth and the wheat crop is making its largest demands on the available supply. A fourth variable was the geometric mean of monthly rainfalls from May to August, which was used as an indicator of the extent of winter drowning on low lying soil types. Abnormally heavy rain in any one or more of these months could detrimentally affect wheat yield.

The remaining four variables related to mean temperatures, but only two had direct effects upon crop yield. Of these, the first was the geometric mean of November and December temperatures, which was used as a measure of the effectiveness of available soil moisture during this period; and the second was February temperature, which indicated the weather conditions during the last half of the harvest. A high proportion of the better yielding wheat crops are harvested during February in New Zealand, and adverse weather conditions at that time may reduce the harvested yield.

---

[3] The construction of a weather index along the lines suggested by Stallings [28] and Shaw [25] was not feasible in this case, as no suitable experimental data was readily available in New Zealand.

Indirect effects of weather on wheat yields

The two temperature variables considered to have an indirect effect upon wheat yield were related to the early and late autumn periods, when land preparation and drilling normally occur. The first variable, the geometric mean of February and March temperatures eleven months before harvest, was thought to affect yields through its marginal effect upon the proportions of different soil types used to grow the crop from year to year.[4] Its behavior for this reason would tend to supplement the once for all adjustment effected by the dummy variable discussed earlier.

Late autumn temperatures were thought to affect wheat yields through their relationship with the flight patterns of the cereal aphid (*Rhopalosiphum padi* L.), this aphid being the main carrier of barley yellow dwarf virus from infected pastures to newly emerging autumn sown wheat crops in New Zealand [19, 27]. Low temperatures during April and May reduce aphid numbers and flights, whereas high temperatures have the opposite effect. As a result, wheat yields should be negatively correlated with the geometric mean of temperatures during this period.

Because other factors that occur later in the season are important in determining the spread of virus infection through a crop, this temperature variable could provide only a partial explanation of the effect of the disease on crop yield. However, it may successfully indicate minor variations in yield, resulting from mild virus infections, which were specifically excluded from the dummy variable specified earlier.

Methodology

Ideally, the weather variables used in the regression model should be indices with weights given to meteorological data from a number of stations, according to the area of wheat grown in each locality. In this instance, because of resource limitations, only data from the Lincoln Meteorological Station were used in defining these variables.

For this to be acceptable, it is necessary that strong correlations exist between the weather pattern experienced in this locality and that experienced in other wheat growing districts. In tests with meteorological data from centers in other important wheat growing districts, simple correlation coefficients with $r > 0.7$ for rainfall data and $r > 0.8$ for temperature data were obtained in all cases, so this requirement is fairly well satisfied.[5]

---

[4] No serial correlation between this variable and February temperature at harvest was apparent in the data ($r = -0.044$).

When the weather factors were incorporated in the model, it seemed appropriate to treat the rainfall variables as normal production inputs and the temperature variables as shift factors.[6] Crop-water relationships are at present the subject of intensive research by both biological scientists and production economists [7], so no claim to biological accuracy is made for this specification.

Technological change

The final variables requiring specification were those concerned with technological changes that directly affected wheat yields. Serious attempts to breed improved wheat varieties in New Zealand began sixty years ago with the work of Hilgendorf at Lincoln College. The progress of this work over the intervening years has been summarized recently by Copp [4]. The first major achievement was the breeding of Cross 7, which was released commercially for the 1934–35 season. This variety possessed excellent milling and baking qualities and was much more suitable for direct heading than the varieties it replaced, but it gave no increase in yield per acre [4, p. 79].

For over twenty years, until the varieties Arawa and Aotea [3] were released in the 1956–57 and 1957–58 seasons, respectively, Cross 7 was the main wheat variety in New Zealand. These new wheats were quickly adopted after showing yield increases in field trials of 17 percent (Arawa) and 25 percent (Aotea) over that obtained with Cross 7 [4, p. 83]. In the 1957–58, 1958–59, and 1959–60 seasons, respectively, these varieties made up 44, 63, and 92 percent of the total wheat received for flour milling. An improved strain of Hilgendorf, a variety of very high baking quality but lower yield, was introduced for the 1961–62 season and became commercially important from the 1963–64 season because it attracted a quality premium.[7]

As an index of these technological changes a variable was specified that indicated the proportion of the total crop acreage made up by the area of

---

[5] In a study of wheat yields in France, Oury [21] found that one set of meteorological data from a centrally located recording station gave regression results very similar to those obtained when weighted weather data from many relevant locations were used. This too, suggests that the use of weather data from only one location in the present study should not prove overly restrictive.

[6] The lowest monthly rainfall recorded in these months, over the seasons considered, was 0.12 of an inch. For this reason, no complications such as would occur with a rainfall record of zero were encountered using this specification.

[7] This wheat variety, named after the pioneer breeder, was first introduced in the 1947–48 season, but was not widely grown because its yield was lower than that obtained with Cross 7. The improved yield of the new strain, together with a 20 cent premium per bushel, has changed this situation, and seed of the Hilgendorf variety has been used to plant approximately a quarter of the crop area in recent years.

Aotea plus two thirds of the area of Arawa in each season.[8] This specification was chosen because it allowed for the time that elapsed before the new high yielding varieties were completely adopted and also took account of the movement away from these varieties in the most recent seasons because of the premium paid for the new strain of Hilgendorf (a wheat with a yield similar to that obtained from the old Cross 7 variety). As an alternative more conventional measure of technological change, an exponential time trend was also specified.

Estimation of the Wheat Yield Model

Data for each of the variables discussed in the previous sections, relating to the fifty seasons from 1917–18 to 1966–67, were utilized in the estimation of the regression model.[9] A (common) logarithmic transformation of the model specified in equation (1) was carried out prior to estimation using the method of least squares. Initially, the influence of the weather variables on wheat yields was assumed to be random because their simple correlations with the dependent variable were very low. For this reason they were excluded from the first stage of estimation in which a step-wise regression procedure was used with the remaining variables.

Best two, three, and four independent variable regressions were estimated, the last of these being

$$\begin{aligned}(2)\qquad \log \hat{Y}_t = \underset{(0.0059)}{1.5123} &+ \underset{(0.0108)}{0.1049X_{1t}} - \underset{(0.0129)}{0.0980X_{3t}} + \underset{(0.0182)}{0.0753X_{8t}} \\ &+ \underset{(0.0351)}{0.1415 \log X_{10t}} \\ R^2 &= 0.900, \qquad d = 1.960\end{aligned}$$

where the figures in brackets refer to the standard errors of the partial regression coefficients and the variables have the interpretation:

X_1 = a dummy variable representing the shift in the proportions of various soil types used for wheat in the 1948–49 and subsequent seasons;

X_3 = a dummy variable representing virus incidence;

X_8 = a variable indicating the proportion of wheat acreage each season which was planted in the high yielding varieties Arawa and Aotea;

---

[8] This specification was used to combine the effects of the two wheats in terms of "Aotea equivalents" since the yield increase from Arawa was only two-thirds the increase from Aotea. After initial popularity, Arawa has been much less widely grown than Aotea in recent years.

[9] For detailed discussion of data sources and the data series for the seasons up to 1963–64, see [15].

X_{10} = the ratio of expected wheat price per bushel at harvest, to fertilizer price per hundred weight, at planting time each season.[10]

All partial regression coefficients were significant at the one percent level and the Durbin-Watson "*d*" statistic appeared to be satisfactory.

The five independent variable regressions obtained when the other non-weather variables were tested with the set of independent variables used in equation (2) were:

$$\begin{aligned}(3)\qquad \log \hat{Y}_t = \underset{(0.0955)}{1.4755} + \underset{(0.0172)}{0.1100}X_{1t} - \underset{(0.0130)}{0.0983}X_{3t} + \underset{(0.0235)}{0.0697}X_{8t} \\ + \underset{(0.0368)}{0.1453}\log X_{10t} + \underset{(0.0406)}{0.0157}\log X_{11t}\end{aligned}$$

$$\begin{aligned}(4)\qquad \log \hat{Y}_t = \underset{(0.0338)}{1.5496} + \underset{(0.0150)}{0.1163}X_{1t} - \underset{(0.0256)}{0.0288}X_{2t} - \underset{(0.0124)}{0.0945}X_{3t} \\ + \underset{(0.0270)}{0.0858}X_{8t} + \underset{(0.0436)}{0.1703}\log X_{10t}\end{aligned}$$

$$\begin{aligned}(5)\qquad \log \hat{Y}_t = \underset{(0.0185)}{1.5082} + \underset{(0.0290)}{0.0986}X_{1t} - \underset{(0.0130)}{0.0982}X_{3t} + \underset{(0.0193)}{0.0740}X_{8t} \\ + \underset{(0.0013)}{0.0003}X_{9t} + \underset{(0.0789)}{0.1250}\log X_{10t}\end{aligned}$$

where

X_{11t} = wheat acreage harvested each season;

X_{2t} = livestock units per acre devoted to livestock each season; and

X_{9t} = a time trend with origin at 1st February 1917 and units of one year.

In none of these cases did the coefficient of multiple determination differ significantly from the figure obtained for equation (2). The added variables in equations (3) and (4) have a partial regression coefficient of wrong sign compared with a priori expectations as a result of multicollinearity with the other independent variables. In equation (5) the partial regression coefficient of the exponential time trend variable, X_9, was less than a quarter the size of its standard error despite the fact that this variable had the highest simple correlation with wheat yield of all those examined.[11]

---

[10] Extrapolative expectations were assumed for wheat pricing, except on certain occasions during the last thirty years of government price control, when the announcement of the (changed) new season's price occurred before planting time.

[11] This was $r = 0.84$. The simple correlation coefficients obtained between the dependent variable and each other non-weather variable examined were significantly different from zero at the one percent level and of correct sign.

Estimating the effects of weather

Although the simple correlations between the weather variables specified and wheat yield were rather disappointing, the partial correlations obtained after allowing for the variables X_1, X_3, X_8 and X_{10} ranged up to $r=0.61$. The full model, including the weather variables, together with the independent variables of equation (2), was then estimated, again using the stepwise technique. The final equation obtained, which included eleven independent variables was

$$
\begin{aligned}
(6)\quad \log \hat{Y}_t = {} & \underset{(0.0999)}{1.3311} + \underset{(0.0047)}{0.0878X_{1t}} - \underset{(0.0054)}{0.0986X_{3t}} + \underset{(0.0121)}{0.0521X_{4t}} - \underset{(0.0159)}{0.0721X_{5t}} \\
& + \underset{(0.0090)}{0.0368X_{7t}} + \underset{(0.0076)}{0.0848X_{8t}} + \underset{(0.0160)}{0.1390 \log X_{10t}} \\
& - \underset{(0.0145)}{0.0651 \log X_{12t}} + \underset{(0.0052)}{0.0506 \log X_{13t}} + \underset{(0.0077)}{0.0699 \log X_{14t}} \\
& + \underset{(0.0047)}{0.0229 \log X_{15t}}
\end{aligned}
$$

$$(R^2 = 0.986;\ d = 1.960)$$

where

X_4 = the geometric mean of February and March (pre-planting) mean temperatures, in units of 10°F;

X_5 = the geometric mean of April and May mean temperatures in units of 10°F;

X_7 = February (harvest) mean temperature in units of 10°F;

X_{12} = the geometric mean of rainfalls in the months May to August in units of one inch;

X_{13}, X_{14} and X_{15} = October, November and December rainfalls, respectively, in units of one inch.

When the variable X_6 (November–December mean temperature) was added to the set of independent variables used in equation (6) the partial regression coefficient obtained in the resulting regression relationship was smaller than its standard error, although of correct sign, while the significance of the other variables was unaffected.

One feature of equation (6), compared with equation (2), are the changes that occurred in the relative size of the partial regression coefficients of the variables X_1 and X_8, when weather effects were allowed for. This suggests that the weather experienced in the set of seasons 1948–49 to 1966–67 was relatively better on average than that in the earlier seasons considered. Consequently, the regression coefficient of the variable X_1 appears to have been inflated by this effect in equation (2), where no explicit allowance was made for weather.

On the other hand, the weather experienced in the sub-set of seasons from 1957–58 to 1966–67 would appear to have been worse than the average of the set of seasons 1948–49 to 1966–67 with the consequent effect that the coefficient of the variable X_8 was underestimated in equation (2), when no explicit allowance was made for weather.[12] These features of the regression results suggest that it may not always be safe to neglect weather effects in time series production function analysis, even when primary interest centers on the estimation of regression coefficients for economic variables open to manipulation by policy makers.

Discussion

The lack of significance of the smooth time trend variable tested in equation (5) as a surrogate for technological change, together with the high level of significance of the specific technological change variable X_8, in equation (6), provide some support for Shaw's hypothesis, that technological changes in specific sectors of the economy tend to be introduced fairly abruptly and at irregular intervals.

Although an exponential time trend, taken alone as a regressor, could reduce by 70 percent the variance of the dependent variable about its (conditional) mean, a more detailed specification of the factors affecting wheat yields permitted a reduction in variance of 98.6 percent without including this surrogate variable. The results obtained certainly support Scott's contention [24, p. 657] "that a time variable may reduce the variance more than can rightfully be accounted for by changes in technology."

When the logarithmic partial regression coefficient of the variable X_8 was evaluated, an expected increase in wheat yield of 21.5 percent was indicated if the variety Aotea was to replace Cross 7 over the entire crop area. This figure is quite close to the increase of 25 percent predicted on the basis of regional trials prior to the release of this wheat.

On evaluating the anti-logarithm of the partial regression coefficient obtained for the variable X_3, an expected decline in yield of 20.3 percent is indicated if a virus attack as severe as those experienced in the past should recur. This figure suggests that the high priority given in recent years to scientific research into control measures for this disease has considerable economic justification.

The effect of the abrupt shift in the proportions of different soil types utilized for wheat growing between the 1947–48 and 1948–49 seasons may be assessed from the anti-logarithm of the partial regression coefficient of the variable X_1. This indicates that a sustained yield increase of approximately 22.4 percent occurred, following the move away from wheat on the less fertile and more drought prone soil types.

---

[12] These observations were supported by an ex-post analysis of estimated weather effects in each season.

For each of the other variables included in equation (6), the expected effect on aggregate average wheat yield of a movement one standard deviation above or below the mean value of the regressor has been set out in Table 1. A yield of 47.15 bushels per acre has been taken as the base point for these measurements, this being the expected yield when $X_1 = 1$, $X_3 = 0$, $X_8 = 0.70$, and all the other regressors take their sample mean values.[13]

Table 1. Estimated effects of variation in certain regressors on aggregate average wheat yield

Regressor	Mean value in sample	Value one standard deviation above mean	Effect of this variation on average wheat yield	Value one standard deviation below mean	Effect of this variation on average wheat yield
			bushels		bushels
Wheat/fertilizer price ratio (X_{10})	1.153	1.548	+1.97	0.859	−1.90
October rainfall (X_{13})	1.451 (inches)	3.258	+1.97	0.646	−1.90
November rainfall (X_{14})	1.795 (inches)	3.112	+1.85	1.035	−1.79
December rainfall (X_{15})	1.811 (inches)	4.279	+0.93	0.765	−0.92
May–August mean rainfall (X_{12})	1.986 (inches)	2.651	−0.88	1.488	+0.89
Early autumn mean temperature (X_4)	59.70 °F.	61.26	+0.88	68.14	−0.88
Late autumn mean temperature (X_5)	50.36 °F.	51.76	−1.09	48.96	+1.10
Harvest mean temperature (X_7)	61.44 °F.	63.43	+0.80	59.44	−0.80

During the last five years of the sample period the wheat-fertilizer price ratio took values nearly a standard deviation above its mean; but following recent increases in fertilizer prices, it has fallen to a value close to the sample mean, thus reducing future yield expectations by approximately 2 bushels per acre.

Among the weather variables, October and November rainfalls appear to have the most critical influence on wheat yield, but each of the other factors isolated apparently can effect year to year variations in yield of the order of ±2 percent fairly frequently. In many instances, the effects of individual influences tend to offset each other, but when several factors move in the same direction together, their combined influence on yield can be very substantial.

---

[13] These values for the variables X_1, X_3 and X_8 were relevant to the situation in the 1967–68 season. The standard error associated with the figure of 47.15 bushels per acre was approximately 0.45 bushels.

In the 1966–67 season, a record average yield of 55.42 bushels per acre was obtained, but favorable weather conditions appear to have been responsible for 6.8 bushels per acre of this yield. By way of contrast, during the 1961–62 season almost all the weather factors were adverse. The yield of 42.06 bushels per acre obtained that season was apparently affected to the extent of 8.1 bushels per acre by the difference between actual and mean weather conditions.

Conclusions

Attention has been focused, in this paper, on various factors that have affected annual aggregate average wheat yields in New Zealand over a fifty-year period. It may be claimed that the regression equation (6) provides a satisfactory analysis of the specific factors associated with yield variation and that, as a result, their relative importance may be estimated. Probably the most interesting finding was that, after allowing for the specific effect of virus disease, for a shift in the proportions of different soil types utilized for the crop, and for changes in an important factor/product price ratio, the only significant technological changes that directly influenced wheat yields were those relating to the introduction of new wheat varieties.

Although an exponential time trend, which might be interpreted as a surrogate for gradual technological change, was more highly correlated with the time series of yields than any other single regressor examined, it failed to attain significance in the multiple regression relationships. The (quite plausible) mis-specification of the effect of technological change on wheat yields, which would have resulted if this time trend variable had been accepted uncritically, should provide a warning for future researchers seeking to separate technological and weather factors when analyzing changes in agricultural productivity.

While the specification of weather factors adopted in this study may be criticized as over-simplified, it does appear to provide reasonable quantitative estimates of the influence of weather on wheat yields. Simple functions of specific weather elements, such as those used here, can never capture all the nuances of weather, but crop yield response often appears to be closely associated with gross changes in certain facets of weather. If the inadequacy of a postulated relationship of this type as a biological explanation of crop response is fully recognized by agricultural economists, there seems to be no good reason, other than pedantry, for eschewing its use, when analyzing technological change over time or forecasting crop yields.

In the present instance, equation (6) seems to be suitable for the specific use of forecasting wheat yields, as well as analyzing the per acre productivity of wheat in New Zealand. This attribute may be important to the New Zealand Wheat Board, which is responsible for ensuring that adequate supplies of milling wheat are available throughout the country at all times and to the transport and flour milling industries in arranging to meet the seasonal demand for transport and storage facilities. At present, pre-harvest estimates of yield are made by the Department of Statistics on the basis of district surveys by Department of Agriculture officers, but the results are not normally published until April or May.

Final yield figures for the 1967–68 season are not yet available, but the pre-harvest estimate of yield was 48 bushels per acre.[14] A guide to the accuracy of this figure may be obtained by estimating the standard deviation of the differences between these estimated yields and actual yields over the previous fifteen years for which comparable estimates were available. The calculations, made without taking logarithms of the data, gave a value of 2.14 bushels per acre for the standard deviation. Using equation (6) for the purpose of forecasting yield, a point estimate of 49.19 bushels per acre was obtained, with a standard error of forecast close to 1.50 bushels per acre.[15] The accuracy of this figure and the usefulness of updated versions of the model for forecasting future yields are matters that time alone can determine.

[14] Figures released by the Department of Statistics in February 1969 suggest that a provisional final yield of approximately 51.93 bushels per acre will be obtained.

[15] In logarithms, the forecast was 1.691919 ± 0.013143. As Goldberger [8] has pointed out recently, this point estimate relates to the conditional median rather than the conditional mean of the distribution of yields. Using the adjustment procedure he suggests, a conditional mean of 49.99 bushels per acre is obtained.

Development of Soviet Agriculture Under a Vintage Model of Production*

Earl R. Brubaker

The purpose of this paper is to examine within the framework provided by a vintage model of productive activity the pertinent evidence on output, inputs, and the age of fixed capital to further understanding of the sources of growth (1928–62) in Soviet agricultural output. The basic procedure consists of tentatively accepting the embodiment hypothesis, which states that any positive growth in factor productivity is the consequence of improved quality of fixed capital. Data on the age of capital are taken as indicative of its technological quality, and implied rates of growth in such quality are computed as a residual. Conclusions drawn from strict acceptance of the hypothesis are tempered to account for additional qualitative evidence and for the possibility that equipment may be a more effective carrier than structures. Everything considered, it seems that the embodiment hypothesis can make a useful contribution to understanding Soviet agricultural development.

SEVERAL careful studies have suggested recently that long-term trends in output of the agricultural sector, like those of an aggregate economy, often can be explained only partially by the corresponding trends in traditionally measured factors of production [14; 21, p. 45]. As a matter of fact, in a number of developed countries, among them the United States [21, p. 57], Canada, the United Kingdom, and the German Federal Republic [9], it seems that for substantial periods the growth of factor productivity[1] on the farm matched or exceeded that of other major sectors.

In the Soviet Union, where right up to the present farming has occupied an especially prominent position in what has become a leading industrial economy, analysis of agricultural productivity is of special interest. Understandably, several attempts have been made to relate trends in Soviet farm output to changes in measurable factor inputs [8, 11, 18]; and for the long-term (1928–62) as well as for the "normal" postwar period, there again appears something of a tendency for growth of output to be faster than that of inputs. The purpose of this paper is to examine, within the framework provided by a vintage model of productive activity, the pertinent evidence on output, inputs, and age of fixed capital, in an attempt to further understanding of agrarian development under Soviet-style socialism.

---

* This paper has been improved by constructive comments of Professor David Granick and the members of his seminar on Soviet economics at the University of Wisconsin, as well as those of an anonymous referee. The work could not have been completed without financial support from the Graduate School and the Russian Area Studies Program of the University of Wisconsin.

[1] In this paper, factor productivity refers to output per unit of combined inputs.

Earl R. Brubaker *is assistant professor of economics at the University of Wisconsin.*

Some Basic Statistical Measures

A summary of the results of a vast and painstaking research effort aimed at obtaining a body of reasonably consistent, long-term, well-defined, and reliable time series gleaned from observation of the Soviet farm sector appears in Table 1. The time periods reflect in part the availability of data and in part an attempt to choose, where information is available, initial and terminal years in which the effects of weather have been judged to be similar, i.e., 1953, 1957, and 1962.[2] Generally the data are from a single monograph, *The Soviet Capital Stock, 1928–1962*, by Moorsteen and Powell [22], but they in turn have drawn when necessary, at times heavily, on the work of other Western researchers.

Table 1. Growth in Soviet agricultural output and inputs, selected periods, 1928–62

Period	Output	Employment	Fixed capital stock			Livestock	Land	Current inputs
			Structures	Equipment	Total			
	average annual percentage change							
1928–37	1.9	0.1	6.9	15.7	8.7	−4.6	2.0	19.4
1953–57	7.6	2.0	7.4	16.2	10.6	2.2	5.4	5.2
1957–62	3.8	0	10.9	7.5	9.5	4.8	2.2	7.2
1953–62	5.5	0.9	9.3	11.3	10.0	3.6	3.6	6.3
1928–62	2.4	0.6	6.0	9.7	6.9	0.3	1.9	9.1

Source: Computed from data in Appendix Table A.1.

Variables measured in value terms are based on data in 1937 prices except when, for analytical reasons [22, p. 281], 1928 prices seem more ap-

---

[2] According to Douglas B. Diamond [8, p. 347] the weather may be described as follows:

Year	Growing conditions	Year	Growing conditions
1950	slightly favorable	1957	normal
1951	subnormal	1958	exceptionally favorable
1952	slightly favorable	1959	unfavorable
1953	normal	1960	normal
1954	normal	1961	above average
1955	normal	1962	normal
1956	above average		

Diamond also suggests that conditions for producing livestock products reflect the weather with a one-year lag. Thus, farm output in 1957 and 1962 have been judged to be similarly affected by weather in both the major farm sectors. Apparently 1953 differed from 1957 and 1962 only with respect to slightly less favorable conditions for producing livestock products, so that comparisons involving average annual rates of growth of output based on 1953 may reflect a slight upward bias. Given that livestock products probably contributed less than half of agricultural output and that a presumably small measurement error is being averaged over a four-year period, it would seem reasonable to expect that any bias would be quite modest.

propriate. In many cases alternative measures in 1928, 1950, or 1955 prices are available, but in general they result in quite similar quantitative conclusions. In any event, the principal purpose here will be to attempt an interpretation of the data based on the assumption that the measurements reflect valid approximations of the "true" values of the variables.[3]

Sources of Growth

Simple inspection of the data on inputs in juxtaposition with those on output can give considerable insight into the connections between them. But even in preparation of these data, substantial assumptions about economic relationships were necessary.[4] If we are willing to experiment with some hypotheses about the lines of interdependence between the variables, it might be possible to comprehend better the Soviet Russian agricultural productive process.

Previous investigators have followed a variety of procedures. Karcz [19] lists and inspects the measures on the various inputs separately, with no attempt at aggregation. Diamond [8] and Johnson [18] consider hypotheses about the nature of the agricultural production function. Johnson expresses the economist's usual preference for the Cobb-Douglas version but, for purposes of comparability with studies of the United States, turns to the infinite-elasticity-of-substitution function; Diamond chooses to aggregate his inputs geometrically. In this study, we employ as the basic analytical framework the embodiment or "carrier" hypothesis, which permits consideration of some additional pertinent information, namely, data on the age of fixed capital.

The carrier hypothesis states essentially that the principal reason for productivity gains has been technical advance embodied in new capital items that reflect in their design and construction a multitude of advances in science and technology. This hypothesis has enjoyed tremendous initial appeal, at least to some degree, because of its consistency with wide varieties of everyday experience as well as with systematic historical descriptions of basic scientific and technological developments. It may be stated fairly rigorously as follows:

$$\text{(1)}\quad \frac{\Delta 0}{0} \approx \left| \frac{\Delta A'}{A'} + d\lambda + \frac{d\lambda(-\Delta\bar{a})}{1 + \lambda(-\Delta\bar{a})} \right| + b\frac{\Delta L}{L} + c\frac{\Delta B}{B} + d\,\frac{\Delta K}{\mathrm{K}} + e\,\frac{\Delta M}{\mathrm{M}} + f\,\frac{\Delta P}{\mathrm{P}}$$

---

[3] In fact, the measures doubtlessly only approximate the magnitudes desired for analytical purposes. The data on capital are particularly suspect, and a comparison with the work of other investigators is made in Appendix A.

[4] It is assumed, for example, that ruble factor costs are indeed appropriate weights for arithmetically aggregating outputs and inputs.

where

$$\frac{\Delta 0}{0}, \frac{\Delta L}{L}, \frac{\Delta B}{B}, \frac{\Delta K}{K}, \frac{\Delta M}{M}; \quad \text{and} \quad \frac{\Delta P}{P}$$

represent the average annual percentage growth in output, labor, land, fixed capital, livestock, and current purchases, respectively; b, c, d, e, and f are the partial elasticities of output with respect to the corresponding inputs;[5] $\Delta A'/A'$ is the percentage growth in factor productivity not attributable to embodied technical change; λ represents the growth in quality of fixed capital; and $\bar{a}$ represents the average age of fixed capital.[6] The hypothesis thus

---

[5] Shares in gross agricultural income in 1937 are taken as approximations of the numerical values of the partial elasticities. The derivation proceeds as follows: Shares for labor, capital, and land implied in [22, p. 371] under alternative assumptions about the interest rate, i.e., as low as eight percent or as high as twenty percent, are averaged. Allocations are made to fixed capital and farm animals in proportion to the valuation of their stocks. The share of current purchases is set at 0.082 [18], and the rest are adjusted so that the sum is one hundred. The result is:

Input	Share
Labor	0.5496
Current purchases	0.0820
Land	0.2185
Livestock	0.0623
Fixed capital	0.0886
Structures	0.0642
Equipment	0.0244

[6] For the convenience of the reader, a summary of the genesis of (1) is presented here. First we recall that, granted certain conditions, the production function with disembodied technical change may be written

$$\frac{\Delta 0}{0} = \frac{\Delta A}{A} + b\frac{\Delta L}{L} + c\frac{\Delta B}{B} + d\frac{\Delta K}{K} + e\frac{\Delta M}{M} + f\frac{\Delta P}{P} \tag{2}$$

where $\Delta A/A$ is a residual including the effects of all factors other than inputs of labor and capital, both of which are unadjusted for quality change. By substituting $\Delta J/J$, the rate of growth of quality-adjusted fixed capital stock, for $\Delta K/K$ and, accordingly, $\Delta A'/A'$ for $\Delta A/A$, we obtain

$$\frac{\Delta 0}{0} = \frac{\Delta A'}{A'} + b\frac{\Delta L}{L} + c\frac{\Delta B}{B} + d\frac{\Delta J}{J} + e\frac{\Delta M}{M} + f\frac{\Delta P}{P} \tag{3}$$

The quality-adjusted capital input is defined as

$$J_t = \sum_{v=0}^{t} K_{vt}(1 + \lambda)^v \tag{4}$$

where t is the date of measurement and v, the vintage, is the date of investment. Thus in weighting the capital items, their age is taken as a proxy for their "quality," which improves at a rate of λ percent each year. It can be shown that

$$\frac{\Delta J}{J} \approx \frac{\Delta K}{K} + \lambda - \frac{\lambda \Delta \bar{a}}{1 + \lambda(-\Delta \bar{a})}\,. \tag{5}$$

The first two terms on the right hand side of (5) approximate the rate of growth of the quality refers to relations between variables on which we have already presented much information but calls also for evidence on three more—growth in the quality of fixed capital stock, its average age, and the net impact of all other factors affecting the growth of output.

The carrier hypothesis, like other production functions, is a statement pertinent to any level of aggregation. It has been made about entire economies including, therefore, the farm sector; and indeed a recent study [26, pp. 975ff] has concluded that technological improvements carried by capital did contribute significantly to growth of output on Israeli *kibbutzim*. The hypothesis is not without plausibility in reference to agriculture in the United States,[7] and at least one analyst of Soviet farming has suggested that availability of the proper machinery is especially important in the USSR where, because of climatic limitations, it is imperative to accomplish such basic tasks as plowing, seeding, and harvesting within an exceedingly short period of time [19].

In the current state of economic knowledge, it is possible to obtain quantitative evidence compressed into a single indicator regarding only one of the added variables, the average age of fixed capital. Taken as a proxy for the average quality of capital, age is in its own right an interesting variable.[8]

---

adjusted capital stock when there is no change in its average age. The third term provides an adjustment to account for changing $\bar{a}$.

Substituting the right-hand side of (5) for $\Delta J/J$ in (3) and rearranging terms, we obtain (1). The interested reader may find a more detailed account of the derivation, with an implementation using data on the aggregate U. S. economy in [23] and a thorough discussion of production functions and technical change generally, in [2].

[7] Griliches [13] has argued that increasing capital quality is an important reason for the apparent rise in factor productivity as often measured for farming in the United States. William McD. Herr [14] also implies that physical capital may be an important carrier of technical advance.

[8] Moorsteen and Powell [22, p. 307], have questioned the use of age as a proxy for quality in the Soviet case because " . . . there is no satisfactory way to date the technology embodied in assets created in any given year." The dating problem stems in part from long periods of production for certain items of equipment.

But the fact that a given model is produced over a long period would not seem to preclude dating of *average* embodied technology. Suppose, for example, that investment is composed of only two capital items, automobiles and carriages, with the former accounting for 5 percent of the total in year 1 and carriages accounting for the remaining 95 percent. Suppose further that 20 years later the shares were reversed. The average technology embodied in the items from the later year would differ substantially from that in the initial year without any model change whatsoever. In fact the piece of equipment perhaps most instrumental in transforming the American economy in recent history, the automobile, gained preeminence through the production of a single model, Ford's model T, for close to 20 years. In a large sector of an economy with many productive activities and a large number of capital items, long model runs would be entirely consistent with fairly steady progress in the aggregate. Thus, technology may very well be regarded as advancing in quantum jumps, introducing a new item with a technique doubly, triply, or even a hundred fold more productive. This model may be produced for a number of years, replacing the item that formerly filled that need. With many innovations in many different productive activities over a number of years, the aggregate process may not be exactly continuous, but the model assuming continuity in the aggregate and on the average may provide a useful approximation to the "truth" in all its complexity. Thus, it would seem

Considered in conjunction with the embodiment hypothesis, it may prove to be even more useful. While some interesting evidence is summarized below, ultimately it is necessary to make an essentially arbitrary assumption about the net quantitative significance of the numerous other factors that might plausibly be connected with changes in productivity. In this paper it has been assumed that in the postwar period unspecified factors, on balance, neither detracted from nor contributed to changes in productivity. It seems likely, therefore, that values for λ, which are computed as a residual, and the absolute values for $d\lambda(-\Delta\bar{a})/1+\lambda(-\Delta\bar{a})$, which in turn depend on λ, are subject to some upward bias.[9]

Paying special attention to the periods chosen for analysis, let us consider now the available information on the age of Soviet agricultural fixed capital (see Appendix Table A.2). The basic pattern of change from period to period resembles in many respects that for the total fixed capital stock [22, p. 336], but important differences do appear. There is a moderate decline in the prewar period amounting to little more than a year between 1928 and 1937. The wartime and postwar changes are rather more dramatic. Thus the available data suggest that the low investment during World War II prompted a rise in $\bar{a}$ to a postwar peak, 15.5 years, that substantially exceeded the 1928 level. But in the 1950's, when investment and retirement of structures accelerated, it declined at a truly spectacular rate to a three-decade, and quite probably alltime, low, 6.6 years, by the latter 1950's. But then the average age stabilized and even showed some tendency to rise again[10] as the growth of fixed capital stock abated. Thus, in Soviet agriculture too, variations in the average age of fixed capital have been prominent.

What are the implications of these variations for the sources of growth in

---

that a dating problem because of long model runs does not eliminate the possibility that a relatively thorough and rigorous investigation of the implications of accepting the embodiment hypothesis may help to clarify its usefulness for contributing to our understanding of growth of agricultural output in the USSR.

It also has been suggested that, because of the perennial dire shortages of spare parts in the Soviet Union, a significant effect of changing average age of equipment may be changing of the fraction operable during the course of a given year. To the extent that this is so, our estimates of the impact of embodied technology are biased in a direction inverse to the movement of $\bar{a}$.

[9] By assuming $\Delta A'/A'=0$, we have

$$\frac{\Delta A}{A} = d\lambda + \frac{d\lambda(-\Delta\bar{a})}{1+\lambda(-\Delta\bar{a})}\,.$$

This quadratic in λ is solved for positive roots only.

[10] The rapid decline in the postwar period as computed here stems to a considerable extent from retirements of aged structures, and their actual occurrence is open to doubt. Therefore a recomputation on the alternative assumption that all structures continued to be used seemed in order The basic pattern remains, however, as the decline in $\bar{a}$ amounted to -0.56 years per year in 1950–58, for example, as compared with -0.94 years per year before, while in 1958–61 there is essentially little change, -0.1 years per year as opposed to $+0.1$ years per year before. Under this assumption the rate of growth of capital stock also would differ slightly, rising from 11.1 percent per year to 12.4 percent per year in 1950–58 and falling from 9.4 percent per year to 8.6 percent per year in 1958–61.

output? The data in Table 2 summarize the results of calculations based on the statistics presented above and, for the postwar period, on acceptance of the embodiment hypothesis as stated in equation (1). It seems hardly worthwhile, however, to attempt full application of (1) to the data on the prewar period. The growth of measured inputs alone more than suffices to explain growth in output. If increases in the quality of capital and declines in its average age made a positive contribution in this period, they were overshadowed and overcome by negative factors. Indeed, it is difficult to analyze farming in the USSR during 1928–37 under the assumption, implicit in the vintage model, that we are studying the behavior of human beings engaged in the "ordinary business of life." As is well known, they were instead in the throes of collectivization and turmoil the extent of which probably no one, including those in the top echelons of the Soviet government, has even a remotely reliable measure.[11]

Table 2. Sources of growth in Soviet agricultural output[a]

Source	Period									
	1928–37	1953–57	1957–62	1953–62	1928–62	1928–37	1953–57	1957–62	1953–62	1928–62
	percentage points					percent of growth rate				
Labor[b]	0.06	1.11	0	0.50	0.33	3	15	0	9	14
Fixed capital	0.77	0.94	0.84	0.89	0.61	40	12	22	16	25
Livestock	−0.29	0.14	0.30	0.22	0.02	−15	2	8	4	1
Land	0.44	1.18	0.48	0.79	0.42	23	16	13	14	18
Current purchases	1.59	0.43	0.59	0.52	0.75	84	6	16	9	31
Total measured inputs	2.57	3.78	2.21	2.90	2.12	135	50	58	53	88
Quality of fixed capital	—	2.31	1.57	2.03	—	—	30	44	37	—
Changes in age of fixed capital	—	1.51	−0.08	0.57	—	—	20	−2	10	—
Total residual	−0.67	3.82	1.59	2.60	0.28	−35	50	42	47	12
Output	1.90	7.60	3.80	5.50	2.40	100	100	100	100	100

[a] Computed from data presented in Table 1 accepting the embodiment hypothesis as formulated in approximation (1). Data may not sum exactly to totals because of rounding.

[b] A preliminary investigation suggests that, in terms of contributions to output as assessed within the framework provided by equation (1), educational capital might have contributed something on the order of less than 0.5 percentage point to growth of agricultural output in the decade of the 1950's. Evidence on levels of educational attainment from [28, p. 17; 29, pp. 78–79 and 123] and associated costs from [6, p. 78], taken together, suggest that as of January 15, 1959, educational capital per man may have been on the order of 1/2 the level for the economy as a whole. On the other hand, inspection of evidence on the comparative progress in educational attainments from [7, p. 809] and [29, pp. 88 and 116] suggests, though not conclusively, that cumulative costs of formal schooling per man may have been growing faster in the agricultural sector. All told, it seems safe to assume that a more extensive calculation will not result in an estimated percentage point contribution vastly different from those computed for the economy as a whole (0.39 in 1950–58 and 0.25 in 1958–61) [2, p. 309]. Thus, a substantial modification of the general conclusions of this paper probably will not be required on this account.

---

[11] Some feeling for the extent of the chaos may be gained from diverse sources. Donald Treadgold [27, p. 272] asserts that at least five million peasants died in the process of collectivization and the resultant famine in 1932–33, and he reports that Stalin revealed to Churchill at Yalta that the figure was really ten million. Robert W. Campbell [5, p. 24] states that "some five million persons were deported or shot." According to Leonard E. Hubbard [15], as many as five million *families* may have been deported to Siberia or the Far North. To maintain perspective, we must recall that the agricultural labor force in 1928 was on the order of thirty-three to thirty-four million [22, p. 365].

Under the circumstances, an inspection of the annual changes in our data, shown in Table 3, may prove useful. It would seem that the impediments to growth were concentrated in the early plan period, when, in addition to the chaos, and doubtlessly in large part as a result of it, labor and livestock inputs suffered four successive and substantial declines in 1929 through 1932. These were offset to some extent by steadily, and apparently notably, rising inputs of fixed capital and land. But the upshot appears to have been a persistent contraction in output. Only in 1933, with the restoration of growth in labor input, was the trend reversed and recovery under way. Presumably growth of aggregate output would again outpace that of combined inputs during 1932–37, but this was a period heavily affected by recovery from the depths of the collectivization crisis. Output had not reattained the 1928 level on a sustained basis even by the latter 1930's.

Table 3. Agricultural output and inputs, 1928–37[a]

Year	Output[b]	Labor	Fixed capital	Livestock	Land
	annual percentage change				
1929	− 6.7	− 2.7	8.0	− 1.5	4.4
1930	− 5.4	− 9.1	5.7	−15.4	7.8
1931	− 8.7	− 5.7	7.9	−22.5	7.2
1932	−10.5	− 5.7	9.6	−22.5	−1.4
1933	9.6	10.2	6.7	−17.0	−3.5
1934	6.2	8.2	8.6	3.0	1.4
1935	17.6	10.7	8.7	17.9	1.0
1936	−10.1	− 7.1	10.2	27.2	0.8
1937	22.2	4.3	12.0	1.6	1.1
Period	average annual rate of change				
1928–32	− 7.8	− 5.8	7.8	−15.9	−4.4
1932–37	6.5[c]	5.0	9.4	5.4	0.1

[a] Unless otherwise noted, data were computed from the sources given in Appendix Table A.1.

[b] Statistics on output are in 1937 prices and are from [22, p. 622].

[c] Based on a three-year average centered on 1937 for the terminal year.

World War II also brought such turmoil, disruption, and displacement that again strict application of our model would seem to bear little promise for fruitful empirical implementation. But it was otherwise after the war. By comparison with most of the preceding Soviet period, the years following 1950 were clearly more amenable to interpretation under a rigorous model rooted in the assumption of normalcy.

In this period, sizable residuals did appear, something on the order of 50 percent of the growth rate of output being unexplained by growth of measured inputs. Thus, in 1953–62, the average growth of output amounted to 5.5 percent a year compared with only 2.9 percent a year anticipated from considering measured inputs alone. Under the carrier hypothesis, the remaining 2.6 percentage points may be distributed between two factors: (1) the declining average age of capital, 0.6 percentage point; and (2) the quality of fixed capital, including the net impact of all unspecified variables, 2.0 percentage points.[12] Thus, it would appear that a substantial part of the residual, over 20 percent in 1953–62, was the contribution of a rapid and once-and-for-all reduction in the average age of capital. Since even a significant acceleration of growth in capital stock probably would not induce much of a further decline in its average age,[13] any future rapid advance of factor productivity similar to that of the 1950's could not draw on this source.[14]

While this interpretation has some appeal, consideration of sub-periods within 1953–62 reveals that it may have been a variable unspecified in our strict vintage model, economic policy, rather than improved capital design that was most influential in stimulating growth of productivity. As a matter of fact, agriculture was still the subject of substantial controversy and change after World War II. Commotion and confusion were far from completely absent, and there was no simple orderly feeding of inputs into the farm sector with easily predictable results. Conclusions gleaned from a rigorous analysis again must be tempered by taking some account of other changes in the environment.

Virtually every account of Soviet agricultural performance contributes to the impression that, besides the drive for collectivization in the early 1930's, there were interspersed throughout the entire plan period many shifts in policy and environment with possibly notable consequences for productivity. It may be useful to recall here that there have been changes in: commodity prices, prices of inputs, tax and procurement procedures, pressure to change the size of private plots and private holdings of livestock, the age-sex composition of the labor force, size of the collective and/or state farms, importance of state farms relative to collectives, the internal organization of state and collective farms, planning procedures and autonomy of the collectives, credit policy, labor input norms for the socialized sector (in effect setting maximum time permitted on the private plots), the basis for sales of feed grains and concentrates to households, the differentiation of procurement quotas by region, the official attitude toward and setting of conditions surrounding operation of collective farm markets, and so

---

[12] The contributions of the declining $\bar{a}$ and the quality of fixed capital are computed as $d\lambda(-\Delta\bar{a})/1+\lambda(-\Delta\bar{a})$, and $d\lambda$, respectively.

[13] See [4] for a discussion of the relationship between the rate of growth of a capital stock and its age.

[14] Students of the Soviet economy generally seem to agree that other sources, including economic policy changes, could substantially affect productivity as usually measured. David Granick [12, p. 256] has argued effectively that organizational change may have had a marked impact on productivity in the Soviet economy.

That such changes could have considerable quantitative significance may be seen from measured advances in procurement prices and real wages of collective farmers:

Indicator[a]	Average annual rate of growth	
	1953–58	1958–61
Procurement prices[b]	13.9	1.0
Real wages[c]	13.5	4.7

[a] See sources for details on definition.
[b] [24].
[c] [25, p. 97].

In other words, collective farmers' real wages almost doubled within a five-year period and continued to grow at the seemingly acceptable pace of almost five percent per annum for several subsequent years. The fact that the initial values in 1953 were abysmally low, even by Soviet standards, may not completely vitiate the effect on incentives. Lazar Volin [33] suggests that a response was clear in the rapid rise in the number of days worked per man on the collective farms, although he also cautions against concluding that there occurred "anything like a corresponding rise in the efficiency of labor."

Regarding the period since 1958, there has been less unanimity among Western scholars who have in some cases reached rather differing conclusions indeed. Compare for example, the interpretation by Durgin [10] with that by Karcz [19]. Durgin views the period from 1952 to 1962 as an essentially uninterrupted march, even if at a fitful pace, toward "monetization" and eventually "free sales," albeit with a state monopoly on one side of the market. Karcz also perceives clear progress in 1953–57 but retrogression thereafter until the installation of the new leadership in 1964. Diamond [8], though less emphatic, similarly stresses retrogression and confusion from continual administrative reshuffle. The extreme diversity of opinion on this period may be seen by comparing the treatments of various scholars regarding the abolition of the machine-tractor stations.

Bearing in mind the above discussion, the results of implementing the rigorous vintage model with data from the subperiods within 1953–62 are of special interest.[17] The decline in average age of fixed capital (see Appendix

---

[17] When dealing with such short periods, the question of possible lags in effects may take on added significance. As the quality of capital improves it may take some time for the farms to "strike their gait" with the new equipment because of the necessity to "learn by doing." This might be of particular importance in agriculture where many operations are performed essentially but once a year. Learning how best to utilize new equipment may take several seasons, whereas in manufacturing the learning process may be compressed into shorter calendar periods. If so, the impact of rapid capital growth and decline in average age may have spilled over into our second subperiod. Normally, one might hope to apply the carrier hypothe-

Table A.2) was concentrated in 1953–57. According to the carrier hypothesis, the growth of factor productivity should be comparatively large in this period, especially since $\bar{a}$ seems to have risen in 1957–62. Inspection of the data in Table 2 indicates that such was indeed the case; growth of factor productivity in 1953–57 was more than double that in 1957–62. Furthermore, it seems that in the first period 40 percent of the residual may have been accounted for by the declining $\bar{a}$. Perhaps even more interesting is the implication that the smaller residual in 1957–62 may be due partially to the *drag* of a rising $\bar{a}$. It seems that despite the essentially sustained contribution from the improving quality of capital, the residual fell because of the rise in average age. On the basis of the evidence presented here, the fall in the growth rate in the second period did stem largely from a reduced growth of inputs, but superimposed on this was the further drag from aging of the fixed capital stock.

In sum, if we abstract from information on economic policy and look at the data for 1953–62, an interpretation based on acceptance of the embodiment hypothesis appears reasonably plausible. If we turn to the subperiods, the predictions of the hypothesis also seem to be consistent with the data. On the other hand, we have practically unanimous expert testimony to the effect that there are other variables, which, though less easily quantified, constitute alternative plausible explanations of the surge in factor productivity in the mid-1950's and of its subsequent ebb.[18] For the period 1953–57, in particular, there is available an impressive body of opinion suggesting that improved government policy could have dominated, and therefore estimates of $d\lambda$ and of $d\lambda(-\Delta\bar{a})/1+\lambda(-\Delta\bar{a})$ under the unmodified vintage model seem clearly subject to upward bias. For this period we have reason, *a fortiori*, for regarding the estimates as an upper limit; but the evidence on the net effect of unspecified organizational factors in 1957–62 seems inconclusive, and, from Karcz's viewpoint, our measures of $d\lambda$ could understate the "truth." There is, however, still another, wider perspective from which to look at the matter.

Disaggregation and analysis of the separate sectors, the nonagricultural nonresidential in [3] and the agricultural here, gives results, which, when focussing on the longer subperiods, further support the carrier hypothesis. In each of the two subsectors, it seems that rather spectacular spurts in productivity came, as the hypothesis would predict, during periods when

---

sis to a period of intermediate range, so that errors from ignoring short-term lagged relationships and measurement error would be small.

We must also remember that the concentration of the decline in the average age of capital in the first subperiod may overstate the "truth" (see footnote 10).

[18] Examination of statistics for another period raises further doubts. During 1949–54 the average annual decline in $\bar{a}$ was even greater, specifically, 1.23 years per year compared with −0.78 years per year in 1953–57. Adjusting partially for the effects of weather by taking three-year averages for output and comparing growth of combined inputs with growth in output one finds, nevertheless, a slightly negative residual for this period.

the age of fixed capital was dropping at rapid rates. In the nonagricultural nonresidential sector, it was during 1928–37 that factor productivity contributed 7.3 percentage points to a 16.2 percentage point growth rate. And of this 7.3 percentage points, 2.8 seem to have resulted from the very rapid decline in the age of fixed capital. In this sector in 1950–58, declines in average age, which by then were much less pronounced, contributed only 0.5 percentage point to a much reduced residual of only 3.6. In agriculture, as we have just seen, it was in the postwar period that the age of capital fell precipitously, and factor productivity, apparently boosted in part thereby, underwent an extraordinarily rapid rise.

In conclusion, the embodiment hypothesis certainly does not constitute the final word on sources of Soviet agricultural growth. Indeed the results of a further investigation focusing on equipment as the most likely carrier of technology (see Appendix B) raises serious doubts. We may eventually find that other models[19] will provide more appealing interpretations of the observations. On the other hand it is interesting to note the broad similarity in the results of this study with those on the Israeli *kibbutzim*. For the present, we suggest with some confidence that the vintage model of production does contribute some insight into Soviet agricultural growth and will continue to deserve attention.

Appendix A—The Data

The data underlying the analysis are presented in Appendix Tables A.1 and A.2. Summary descriptions of the data and/or the methods used in its compilation, along with references to the literature containing more detail, are provided in notes to the tables.

Reliability of data on capital

Seriously questioning the reliability of their data on agricultural capital stock, Moorsteen and Powell [22, p. 85] use it only to suggest how the aggregate capital series might have behaved differently from the nonagricultural sector. Thus, it seems especially appropriate to compare their results with those from previous studies. For a substantial number of overlapping years, clear conceptual differences notwithstanding, their data correspond, in at least some respects, reasonably closely to those used for more extensive analytical purposes by Johnson [18] and especially Diamond [8]. Even after taking note of the conceptual disparities, however, some disturbing numerical divergencies appear.

---

[19] Some of them, such as those involving, for example, constant elasticity of substitution other than one, variable elasticity of substitution, nonneutral technical change, and so on, have already been elaborated in some detail.

Appendix Table A.1. Soviet agricultural output and inputs, selected years, 1928–62

Year	Output[a]	Inputs					
		Employment[b]	Fixed capital stock[c]		Livestock[d]	Land[e]	Current purchases[f]
			Structures	Equipment			
	billion rubles	1937 man-years	billion rubles			million hectares	index (1928 = 100)
1928	59.0	33.8	17.8	3.3	48.1	113.0	100
1937	65.1	34.0	32.4	12.3	31.4	135.3	590
1953	81.6	38.5	58.0	29.3	39.1	157.2	1115
1957	109.4	41.6	77.1	53.5	42.7	193.7	1366
1962	131.6	41.7	129.1	76.8	54.2	216.0	1931

[a] The Moorsteen-Powell index of agricultural production begins with data on gross physical output from series compiled by Johnson and Kahan [18], supplemented where necessary by corresponding official information. The physical output series were weighted arithmetically with average realized 1937 prices, and the resulting series was adjusted for net changes in livestock herds.

Sources: [1, p. 52] and [22, pp. 361–2, 621, 625].

[b] The data are adjusted for changes in the number of man-days worked per year but not for the number of hours per day. Officially reported statistics on employment in state and institutional farms, Machine Tractor Stations and Repair Technical Stations, and state agricultural services constitute the basis for estimates. Man-day inputs on collective farms and private plots were estimated by Miss Nancy Nimitz from diverse sources including sample data, and these were converted to man-year equivalents by Moorsteen and Powell based on the days worked per year in large-scale industry. Allowance was made for nonagricultural productive activities of persons engaged principally in agriculture. Thus, the data constitute a sheer physical measure with no adjustment for changes in age, sex, or other indicator of quality.

Sources: [1, p. 26] and [22, p. 365].

[c] The statistics on agricultural fixed capital stock were obtained as the difference between the Moorsteen-Powell series on the total and nonagricultural capital stocks. The data reflect initial stocks of structures and equipment as of January 1, 1928, as estimated in [22, p. 49] from information in a document of the Soviet State Planning Commission. For subsequent years, stocks as of January 1 were computed by adding gross investment and deducting retirements.

Investment in structures was obtained by applying Soviet current price data on the distribution of investment between agricultural and nonagricultural structures to the figures for total construction. The estimated stocks of agricultural structures consist of items used directly in production, including, for example, irrigation works, but excluding residences and cultural or industrial capital located on the farms.

The equipment component reflects stocks and flows of "agricultural machines, tractors, trucks, and other means of transport (for example, horse drawn vehicles)." For 1928–35 and 1956, investment data in current prices are deflated to 1937 values. For intervening years, investment was interpolated on deliveries to the farms where possible and on production elsewhere. For the years following 1956, estimates were made by extrapolation on an official series. In general, it may be said that the data provide a splendid example of the incredibly complex detective work based on extremely diverse bits of evidence that have been necessary to form a Western picture of Soviet economic "reality." Moorsteen and Powell provide an admirably detailed presentation of their sources and procedures in [1, pp. 11–12] and [22, pp. 49–50, 84–87, 427–42].

[d] Data are from [1, p. 16] and [22, p. 337]. The authors [22, p. 102] provide the following description: "The value of capital in livestock is calculated from stocks measured in physical units . . . and from average realized prices. . . . The estimates take account of changes over time in the average weight of animals in the herds but not of other qualitative changes such as in age or breed. They include cows, other cattle, hogs, sheep, goats, and horses, but omit rabbits, fowl, bees, camels, mules, buffaloes, and the like."

[e] Information on land includes sown area, omitting fallow and pasture.

Sources: [1, p. 27] and [22, p. 250].

[f] For the period since 1950 the index in [8] was used. It includes fertilizer, electric power, fuels and lubricants, current repair services, and industrially processed feedstuffs. For overlapping years, it shows very close correspondence with the index based on fertilizer and petroleum products from [18]. The latter index has been used for the period

Appendix Table A.2. Average age of Soviet agricultural fixed capital, January 1, indicated years[a]

Year	Average age		Year	Average age	
	Equipment	Total fixed capital		Equipment	Total fixed capital
	years			years	
1928	3.01	12.16	1946	7.25	15.15
1929	3.49	12.23	1947	6.83	15.45
1930	3.73	12.38	1948	5.83	15.47
1931	3.49	12.29	1949	4.45	15.07
1932	3.17	12.04	1950	3.08	14.11
1933	3.07	12.10	1951	2.52	12.34
1934	2.84	11.84	1952	2.48	10.89
1935	2.74	11.65	1953	2.69	9.79
1936	2.62	11.37	1954	2.92	8.92
1937	2.69	10.96	1955	3.19	8.11
1938	3.12	10.75	1956	3.37	7.30
1939	3.62	10.81	1957	3.50	6.66
1940	4.32	10.97	1958	3.56	6.62
1941	4.69	11.25	1959	3.52	6.58
1942	5.00	11.81	1960	3.61	6.69
1943	5.85	12.71	1961	3.80	6.89
1944	6.60	13.63	1962	3.92	7.08
1945	7.11	14.45			

[a] Ages for items in the capital stock as of January 1, 1928 [22, p. 50] were averaged using gross value weights. Year-to-year changes reflect the dates and gross values of subsequent investment and retirements. See also [22, pp. 96ff].

In the following tabulation Johnson's preliminary estimates of agricultural capital services (primarily machinery and draft animals) are presented along with data of approximately like scope from Moorsteen and Powell:

Period	Average annual rate of growth	
	Capital stock (1955 prices)	Capital stock[a] (1950 prices)
1928–38	−0.3	3.5
1938–50	−0.2	− 2.3
1950–55	9.2	21.0
1955–59	5.8	12.6

[a] Includes machinery and horses [22, pp. 105, 107, 325, 328].

Even after allowing for differences in scope (Johnson's data presumably include: (1) some items other than machinery; and (2) draft animals other than horses), in price weights, and in concept (capital services as opposed to capital stock), the disparities seem pronounced to say the least. Johnson's data show for practical purposes no change between 1928–38 and 1938–50, while those of Moorsteen and Powell show a swing from decidedly positive to negative. For the postwar periods the growth rates implied by the Moorsteen-Powell data are more than double those presented by Johnson. On the other hand, the orders of magnitude for 1928–50 are similar. Furthermore, both computations agree that there was a general and exceptional acceleration after World War II and that there was a marked deceleration in 1955–59 as compared with 1950–55.

Compare also, however, the rates of growth of capital stock, the concept used in this paper (implied by the data of Moorsteen and Powell), with those published by Diamond, who uses basically the Soviet official statistics on capital stock and investment:

Average rate of growth of Soviet agricultural fixed capital

Period	Diamond	Implications of Moorsteen Powell in prices of:	
		1937	1950
1950–58	11.2	11.1	10.9
1958–62	10.0	6.2	8.9

The correspondence is all the more remarkable in view of the obvious differences in the underlying data. Diamond's estimates are in 1955 prices. They include draft animals, and they refer to midyear values. Although he depends essentially on the official Soviet figures, he also reports checking his published estimate against an independently constructed index of machinery stocks and agricultural structures, finding only an approximately five percent difference from the official index in 1962 (starting with both equal to 100 in 1928).

Another indicator of reasonable reliability is the behavior of the annual data. As may be seen in Figure 1, the growth rates for each of the twelve overlapping postwar years compare closely in order of magnitude and show a tendency to a similar pattern of change—decline in the early 1950's, resurgence in the middle 1950's, followed by another decline in the late 1950's and early 1960's.

On balance, it will be well to remember that when the archives open and a more reliable index of capital inputs into Soviet agriculture may be constructed, further adjustments probably will be necessary. In the meantime the Moorsteen and Powell data present several advantages: (1) annual measures over lengthy spans; (2) consistency with other variables; and (3) above all, detail on compilation and description of procedures with the consequent possibility for calculating average age. Furthermore, the similarity of at least some of the independent measures for the postwar period may inspire some confidence in the reliability of the numerical values for the later period at least.

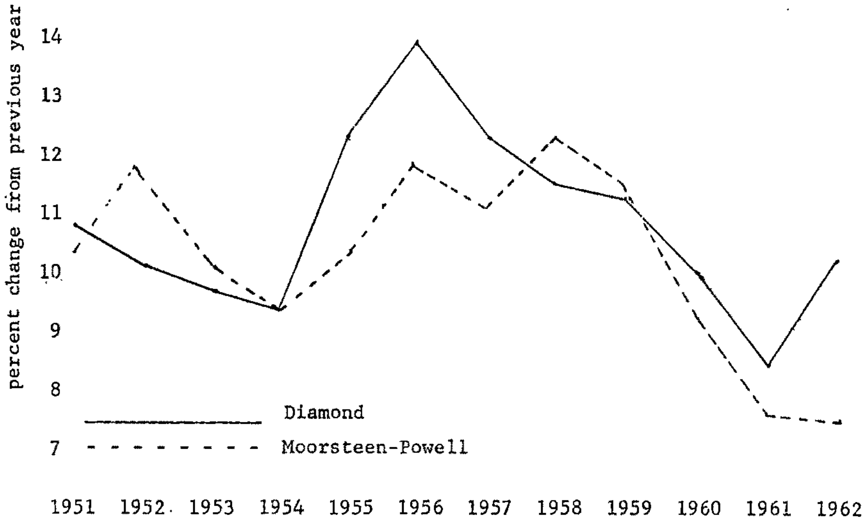

Figure 1. **Annual percent change in Soviet agricultural fixed capital, 1951–62**

Appendix B—An Alternative Hypothesis: Equipment as Sole Carrier

Aggregate analyses involving the embodiment hypothesis generally have employed a comprehensive concept of capital, including equipment and structures. A plausible refinement suggests that we focus on equipment alone, since it appears likely to be especially effective as a carrier of new technology. Some feeling for the importance of technical advance embodied in agricultural machinery may be gained by examining the data presented in Table B.1. on mechanization of some major Soviet farm activities. It would seem that, even after allowing for the fact that data in the official statistical handbooks may be selected to create a favorable impression, the real gains probably were substantial. The apparently great strides forward in mechanization during the 1950's would seem to support the notion that technology carried by equipment may well have been important, if not predominant, in advancing factor productivity.

Then, too, it was during the early to mid-or-latter 1950's, when the first important growth in factor productivity appeared, that the composition of Soviet agricultural capital stock altered drastically, and again probably unprecedentedly, in favor of equipment (from 25 percent of the total in 1950 to almost 70 percent in 1957). Thus a preliminary inspection of some relevant data tends to increase confidence in the possible usefulness of the alternative hypothesis.

This is not to say that structures do not carry new technology or that

Appendix Table B.1. Mechanization of selected productive activities on Soviet collective and state farms[a]

Activity	Year				
	1945	1950	1955[b]	1960	1964
	percent of total				
Sowing					
grain	39	75	94	100	100

[a] Unless otherwise noted, data are from [32, pp. 158–159].

[b] Based on data in [30, p. 143] covering collective farms only and therefore probably subject to downward bias. Data for 1965 [31, p. 400] suggest that collectives generally lagged somewhat behind the state farms in their level of mechanization.

they might not be necessary complements to machines, constituting therefore an essentially indivisible package in which society must invest in order to obtain the benefits of the new techniques more clearly carried by equipment. Electric power lines, for example, though structures, may embody new technology in the sense of more effectively transmitting electricity. They are also clearly essential to the operation of certain pieces of equipment installed on the farm. In fact, one may wish to view them, though nominally structures, as an essentially integral part of the equipment actually in use on the farm.

Normally one would expect, however, that the rate of improvement in structures per se would be far less than the average for all fixed capital. Suppose we examine the possibilities for employing the alternative hypothesis to interpret the evidence on Soviet agricultural development. We shall see that a strict extension of the analysis in the text raises further doubts about the usefulness of the carrier hypothesis.

In the first place, the 1937 weight for fixed capital, including structures, is only 0.0886; equipment in turn accounted for less than 30 percent of agricultural gross capital stock. The embodiment hypothesis thus puts the burden for carrying technology (and explaining an occasionally large residual) on a productive agent whose own weight in the national income is quite small. In those cases where $\Delta A/A$ is substantial, the rate of improvement in the quality of equipment (λ_q) will have to be rather large.[20]

---

[20] Ezra Sadan's study of embodied technology in Israeli cooperative farms [26, p. 975] found by regression a similarly low value (0.03) for the partial elasticity of output with respect to inputs of equipment (defined as items with service life of ten years or less).

Furthermore, there are complications suggested by the alternative interpretation due to the extremely uneven changes in the stock of agricultural equipment and consequently in its gross value weighted average age, (a_q). The decline during World War II and the recovery in the period immediately following were much more pronounced in stocks of agricultural equipment than in structures. There were substantial successive reductions in each year, 1942 through 1947. Although some of the decline apparently did represent retirement of aged, wornout items, it also reflected the low levels, and in some years utter lack of gross investment during the war. The upshot was that a_q seems to have reached over 7 years by the end of 1945, i.e., a level not quite 3 times as high as the prewar minimum computed for January 1, 1936.

Under these conditions, a return to more nearly normal growth of investment had the inevitable numerical consequence that values for a_q fell rather rapidly. By the early postwar period, retirements of equipment acquired in the latter 1930's were becoming substantial, and their impact on a_q was especially apparent, so that it began to decline even before growth in the stock of equipment reappeared. As reconstruction progressed, annual investment in equipment became very large relative to existing stocks; and the growth of the equipment stock ($\Delta K_q/K_q$) accelerated to clearly unsustainable rates, capped by an extremely atypical 98.8 percent spurt in the two years 1950–51 with successive rises of 36 and 46 percent, respectively. In the subsequent years the growth rate necessarily ebbed rapidly.

The movement of a_q (see Appendix Table A.2) reflects, of course, these diverse currents. There was a spectacular descent from 7.2 years at the end of 1945 to 2.5 year by the end of 1950. When $\Delta K_q/K_q$ receded to more nearly normal levels, though remaining probably still quite high by many standards, a_q actually began to rise through the remainder of the 1950's.

Strictly speaking then, the alternative hypothesis would predict a boost to productivity in the early postwar period, followed by a drag throughout the 1950's. Suppose that we were to choose the periods 1947–50 and 1953–57 on the basis of substantial variation in the variable of primary interest in the vintage interpretation, a_q. What values would be obtained for λ_q and $d'\lambda_q(-\Delta a_q)/1+(\lambda_q)(-\Delta a_q)$?[21] The outcome in this case is the reverse of expectations based on the carrier hypothesis. Specifically, in 1947–50 all measured inputs grew faster than output, so that regardless of the weights, or the elasticity of substitution for that matter, no residual remains to be explained. Furthermore, one might suspect that during this period of reconversion and reconstruction the average quality of the labor force improved considerably and that restoration of idle machinery contributed importantly to restoration of output. These factors, along with the rapid reduction in a_q under a strict implementation of the carrier hypothesis,

---

[21] The prime on d denotes that the weight refers to equipment alone.

Characteristics and Salaries of Agricultural Economists*

EMANUEL MELICHAR

Employment and salary characteristics for agricultural economists as of 1966 differ from those of general economists and other scientists in several respects. Educational institutions employed 58 percent of agricultural economists as against 45 percent of economists generally and 36 percent of all scientists. Only 9 percent were employed by business and industry as compared with a third of all economists and 41 percent of all scientists. The geometric mean basic salary received by agricultural economists was $13,000 as compared with $13,600 for all economists and $12,100 for all scientists. Academic degree attained and length of service have a greater influence on salary variation than age, type of employer, or primary work activity.

THE NATIONAL SCIENCE FOUNDATION has biennially since 1956 compiled a "National Register of Scientific and Technical Personnel" to provide statistical information on the supply, utilization, and characteristics of the nation's scientists. Economists were first included in the 1964 register, at which time agricultural economists were grouped with specialists in forestry and fishery economics to form a subclass of land economists. In 1966, however, agricultural economics was identified as a separate specialty and 1,204 individuals, 9.2 percent of all economists responding, indicated it as the area in which they had greatest scientific competence.

In addition to their professional field and specialty, registrants reported salaries, professional incomes, and characteristics such as age, sex, highest academic degree, length of experience, type of employer, and primary work activity. After the 1964 and 1966 surveys, the American Economic Association published distributions of all registered economists by these characteristics, as well as analyses that attempted to isolate and quantify the influence of each characteristic on salaries received [1, 3]. Similar data and analyses are here presented for agricultural economists in the 1966 register. Insofar as possible, comparable data for all economists and all scientists are also shown.

---

* The cooperation of Milton Levine, Study Director, and J. James Brown, Associate Study Director of the National Register Group of the National Science Foundation is gratefully acknowledged. This article supplements the more general study of economists in which the author participated. See [3].

EMANUEL MELICHAR *is an economist in the Division of Research and Statistics, Board of Governors of the Federal Reserve System.*

Characteristics of the Profession

The NSF attempts to secure a report from every individual in each field of science covered by the National Register. It fails to reach such ultimate perfection, of course—first, because it probably does not get a questionnaire to every eligible individual, and second, because some individuals do not return their questionnaires. Thus, for the data that follow, neither universe coverage nor scientific sampling can be claimed; however, a representative group of agricultural economists appears to have responded, undoubtedly due in large part to use of the AAEA membership list.[1]

As a group, agricultural economists exhibited a relatively high level of formal training. Nearly three-fifths had a Ph.D. degree, compared with fewer than one-half of all economists (Table 1). Most of the remaining agricultural economists had received a Master's degree, whereas 21 percent of all economists and 29 percent of all scientists had only the Bachelor's degree.

Distributions of agricultural economists by age and length of experience resembled those of all economists and all scientists. Although a noticeably smaller proportion was under 30, this difference appears related to the finding that most agricultural economists obtain higher degrees and thus enter the profession at a more advanced age.

It is hardly news that most agricultural economists are employed by universities and the federal government, but still interesting to compare the relative proportions with those for other professions. Educational institutions employed 58 percent of agricultural economists, as against 45 percent of economists generally and 36 percent of all scientists. One-fourth worked for the federal government, about double the proportion among the other groups. Only 9 percent were employed by business and industry, compared with a third of all economists and 41 percent of all scientists.

Primary work activities most frequently reported by agricultural economists were research, management, and teaching, in that order. Forty percent listed research—mostly applied research—as their primary activity, which was more than twice the percentage among all economists and also slightly higher than the proportion among all scientists. Another 13 percent were engaged primarily in management of research activities, while 14 percent managed other endeavors. Only 18 percent named teaching as

---

[1] Distributions cited here have been restricted to persons who reported basic salary. As compared with all registrants, this group may be more representative of working members of the professions because respondents who did not report salary were concentrated among young persons who were likely still in graduate school and older persons who appeared likely to be retired.

Other	14.9	—	—	14,500	—	—

their primary activity, compared with 30 percent of all economists. "Extension" was not listed on the questionnaire.

In the 1966 survey, agricultural economists were offered a choice of four specialties—finance and marketing (chosen by 40 percent), farm management (20 percent), production economics (22 percent) and processing of farm products (3 percent). The NSF appears to have been poorly advised in formulating these groupings. An improved selection of specialties has since been offered in the 1968 survey: demand and supply analysis, situation and outlook, policy, finance, marketing, farm management, and land reform.

Salaries

The geometric mean basic salary received by agricultural economists in 1966 was $13,000—somewhat below the mean of $13,600 for all economists but considerably above that of $12,100 for all scientists.[2] Direct comparison of these averages may be misleading, however. For instance, most agricultural economists employed by educational institutions worked for a full calendar year, whereas most other university economists reported a basic salary covering only an academic year of 9 to 10 months. Or, as already noted, agricultural economists on average were older and had more advanced degrees—factors that should also tend to increase salaries, other things being equal. Thus a regression analysis of economists' salaries that allowed for the influence of such characteristics revealed that specialization in agricultural economics was associated with slightly greater salary disadvantage than indicated by gross salary averages. Along with specialists in economic history and land economics, agricultural economists were found at the lower end of the pay range—tending to have basic salaries 5.7 percent below the average for all economists and about 10 percent below those paid to persons in specialties at the top of the range—monetary and fiscal theory and international economics [3, pp. 76–77].[3]

---

[2] The NSF has always used salary medians rather than other averages in its National Register publications—a sound practice in that medians are less affected by extreme values [4]. However, because salary medians were not available for many classes used in this paper except at prohibitive cost, geometric means (means of logarithms of salaries) were chosen in preference to arithmetic means because the geometric means are also less affected by extreme values and because their use parallels the use of logarithms of salaries in the regression analysis that follows. For comparison, the following were national median, geometric mean, and arithmetic mean salaries, respectively, in agricultural economics: $12,900, $13,000, and $14,000; in economics: $13,100, $13,600, and $15,000; in all fields: $12,000, $12,100, and $13,000.

[3] A comparison in terms of total professional income would probably be still more unfavorable to agricultural economists. Salary supplements received by economists in 1964 were found to be relatively low among (1) academically-employed persons paid a calendar-year basic salary and (2) persons employed by the federal government [3, pp. xxix-xxxv]. Three-fourths of all agricultural economists belonged to one or the other of these groups in 1966.

In an interesting parallel, agricultural scientists had one of the lower salary medians among all professions, 17 percent below that for all scientists, whereas the median for economists was 9 percent above that figure. When salary was regressed on professional characteristics, specialization in economics continued to show a net positive influence on salary—second only to that exerted by mathematics—while specialization in the agricultural sciences had by far the most adverse influence on salaries among the 13 fields covered. Net regression coefficients indicated that salaries of agricul-

Intra-profession differences in average salaries among classes such as employer and age groups may also be misleading because of intercorrelations. For example, economists with more experience, or higher degrees, or management responsibilities tend to be paid more; but these characteristics are often associated. How much of the higher pay, therefore, can be attributed to each characteristic—e.g., how much of the higher salary of older economists is a reward for their added experience rather than for their generally higher degrees or the management responsibilities they have assumed?

To separate and quantify intercorrelated effects, multiple regression analysis is indicated. Thus, for agricultural economists, salary (in logarithmic form) was regressed upon the six major characteristics listed in Table 1 (sex was omitted). The logarithm of salary was used as the dependent variable, so that the net influence of each characteristic would be measured in proportional rather than absolute terms, with the cumulative effect of all characteristics multiplicative rather than additive. A dummy variable was used to represent each class of each discrete characteristic and each class interval of the age and experience characteristics, in the latter case permitting anticipated nonlinear effects to be picked up [2]. A two-way interaction expected between type of employer and length of experience was represented in the regression model by providing a separate set of dummy variables to represent length of experience for each of the three major employer groups—educational institutions, government, and other (primarily industry and business). Similar regression models were also estimated for all economists and all scientists.

Relative net influence of characteristics

The relative contribution of each characteristic toward explanation of salary variation is indicated by the coefficients of partial determination listed in Table 2.

The academic degree attained by the respondent exerted the greatest net influence on salary, not only among agricultural economists but also among all economists and all scientists. Length of experience likewise explained a relatively high proportion of salary variation among agricultural economists, whereas the type of employer and the primary work activity had less effect. Age was relatively unimportant after experience and degree were taken into account. The agricultural economic specialty, as specified in the 1966 questionnaire, proved least important in explaining total salary variation, though it was just significant at the .05 probability level. Similarly, the specialty within economics was relatively unimportant in this respect, though as already noted a substantial salary difference was

---

tural scientists tended to be 21 percent below those of economists and 16 percent below the average for all scientists [3, pp. 66–68].

Table 2. Importance of selected characteristics in explaining salary variation, National Register, 1966

Characteristic	Importance of net relationship (partial R^2)

* Significant at the .05 probability level. All other relationships are significant at the .01 probability level.

found between the specialties at the high and low extremes of the salary range. Among all scientists, the field of work did exert considerable net salary influence.

Net relationships

Net relationships between salary and the various characteristics are quantified by regression coefficients and presented in Table 3 as net percentage differences from the geometric mean salary of each of the three professional groups. For agricultural economists, the net relationships that emerged from the regression of salary on all six characteristics simultaneously (column 2) may be compared with gross relationships (column 1) computed from actual geometric salary means (or obtained by regression on only the characteristic concerned)

Experience and employer.—For agricultural economists with each major employer, the net progression of salary with added experience was less marked than gross salary averages might have led one to suppose, as some of the progression is ascribed to attainment of higher degrees, movement into management positions, and advance in age.

At the beginning of their career, agricultural economists employed by business appeared to be at a salary disadvantage compared to their counterparts in government and universities. Such early disadvantage in business employment was not found among all economists or all scientists. At the other end of the experience range, however, all three professional groups obtained higher salaries from business than from other employers.

[a] Calendar years.

For example, agricultural economists with 30 or more years of experience tended to earn 11 percent more in business than in the federal government and 31 percent more in business than at educational institutions.

For both agricultural economists and all economists, net salary progression with added experience was greatest in business and least at educational institutions. Between the class of agricultural economists with 2 to 4 years of experience and that with 30 or more years, the total net salary gain attributed to added experience was 102 percent in business, 48 percent in government, and 33 percent at colleges. If one assumes that this period covers 30 years, the net average annual rate of such progression was 2.4 percent in business, 1.3 percent in government, and 1.0 percent at colleges. These large differences made interaction terms necessary in the regression analysis; conversely, the differences were picked up in the analysis only because the interaction terms were included. In contrast to the finding for economists, salary progression among all scientists was about the same for all three major employer groups, averaging about 1.5 percent annually.

Highest academic degree.—Among agricultural economists possession of the Ph.D. degree tended to yield a 22 percent net salary advantage over the Master's, a shade less than among all economists and all scientists. The Master's degree carried a negligible advantage over the Bachelor's among both agricultural and all economists, but a more significant advantage among all scientists. The relative salary value of these degrees was thus clarified by the multivariate analysis, for gross salary averages had shown that holders of the Bachelor's degree earn more than persons with the Master's. This perverse gross relationship was found among all three professional groups and was particularly pronounced among economists.

Primary work activity.—Compared with all economists and all scientists, agricultural economists were rewarded slightly less for management duties, substantially less for research, and considerably more for teaching. Teaching exhibited a small salary advantage over research among agricultural economists, whereas research had a large advantage over teaching among both all economists and all scientists. The joint research-teaching appointments commonly used in agricultural economics may be responsible for this difference.

Future Analyses of National Register Data

The preceding structural data and analysis of salary variation for agricultural economists represent only an initial instalment of the flow of information potentially available from the binennial NSF survey of the profession. In addition to updating the cross-sectional view, future studies may profitably employ some of the many additional characteristics about which data are obtained, such as colleges attended or institutions where now employed. The NSF has also arranged its files to permit studies of factors affecting the mobility and progress of individuals after data have been collected over a longer time span.

These potential analyses of the profession of agricultural economics clearly hinge on continued support of the NSF survey through a high and representative level of voluntary response to the NSF questionnaires. As economists, we are more often engaged in surveying others rather than in being surveyed and thus can readily appreciate that high participation rates are needed to provide the degrees of freedom required for more detailed and sophisticated analyses, and that repeated biennial participation is necessary if future longitudinal studies are to be possible. Every member of the profession should take care to fulfill his seemingly small but very vital role in this endeavor.

Research Notes

Note on the U.S. Demand for Coffee[*]

JOHN J. HUGHES

FOUR postwar estimates of the demand function for coffee in the United States, derived from time series, have given elasticities for income between .22 and .60 [1, 2, 4, 5]. Two of the studies [1, 5] noted that the income elasticities using only postwar data were much smaller than the elasticities from the interwar period, and both suggested plausible reasons for the difference: (1) the changed age distribution of the population in the postwar period, important because coffee drinking is negligible for children and small for teenagers compared with adults; (2) the growth in consumption of instant coffee, which uses less green coffee beans than regular coffee; and (3) a steadily rising extraction rate of instant coffee from a given amount of green beans.

While it is true these factors have worked in the expected direction in the postwar period, they cannot be the major reasons for the reduced income elasticity since it can be shown that, even after correcting for them, the income elasticity is actually negative in the postwar period.

The demand function employed in these studies was $Q = f(Yd, rP)$, where Q is the quantity of green beans consumed annually, Yd is aggregate real disposable income, rP is a weighted average of the prices of regular and instant,[1] deflated by the all-items CPI. Q and Yd are deflated by specific populations.[2]

Estimates of the demand parameters are shown in Table 1 for the best-fitting, linear versions for two periods, 1920–41 and 1947–66,[3] for three populations—total, fourteen years and older, and 20 years and older[4]—and, in the postwar period, for two quantity series—the actual amount of green beans consumed and a "corrected for instant" quantity, identified as Q'.

---

Table 1. Demand equations for coffee[a]

Equation[b]	*by*[c]	*Ey*[d]	*brp*[c]	*Erp*[d]	$\bar{R}^2$	*DW*[e]
(1) 1920–41, total population	4.21 (4.65)	.338	−.084 (−7.60	−.302	.758	2.25
(2) 1920–41, 14 and over	3.92 (4.31)	.315	−.104) (−6.88)	−.271	.707	2.38
(3) 1947–66, total population	−5.05 (−7.77)	+.568	−.030 (−3.97)	−.143	.74	1.86
(4) 1947–66, 14 and over	−2.79 (−5.48)	+.315	−.033 (−3.41)	−.113	.59	2.14
(5) 1947–66, 20 and over	−3.03 (−4.48)	+.272	−.050 (−4.65)	−.148	.58	2.23
(6) 1947–66, Q', total population	−2.72 (−3.97)	+.290	−.033 (−4.18)	−.150	.51	2.10
(7) 1947–66, Q', 14 and over	−.731 (−1.19)	+.078	−.039 (−3.31)	−.125	.28	1.84
(8) 1947–66 Q', 20 and over	−.118 (−.143)	−.010	−.058 (−4.43)	−.163	.49	1.87

[a] The variables in all cases were: *Q*, per capita pounds of green beans; *Yd*, per capita disposable income in thousands of 1957–59 dollars; *rP*, the average retail price of coffee in cents per pound deflated by the all-items CPI.

[b] The means of the *Q*s for equations (1) through (8) are: 17.6; 24.1; 16.1; 22.4; 25.6; 17.0; 23.6; 27.0.

[c] *by* and *brp* are the regression coefficients for *Yd* and *rP*. The figure in the parenthesis below the coefficient is the ratio of the coefficient to its standard error or t.

[d] *Ey* and *Erp* are the elasticities of quantity with respect to income and relative price, respectively, evaluated at the means.

[e] *DW* is the Durbin-Watson statistic.

The correction for instant coffee and the increasing efficiency of the extraction rate required conversion of the instant coffee consumed each year into the equivalent number of green beans required for regular [5, pp. 25–26]. An adjustment was made each year for the changing extraction rate [3, p. 124]. The series is thus the sum of green beans used for regular and the green beans that would have been used if the instant coffee consumed had been regular.

The negative sign of the income coefficient in all the postwar equations 3 through 8 contrasts sharply with the significantly positive sign in the in-

---

ment of Commerce [5] use total population. Rhomberg deflates the coffee price by the implicit price deflator for non-durable consumer goods.

[3] Calculations were also made for semi-log and log-log function forms.

[4] There are complications with the 20 and over population; while it is the most appropriate deflator for the quantity series, its use in deflating the income series transfers the income earned by those less than 20 to those 20 and older, and, moreover, assumes (as does the 14 and older to a lesser extent) that infants, children and teenagers do not consume economic goods. Equation 8 used the population 20 and over to deflate the quantity series and, as a convenient approximation to the required equivalent adult measure, the population 10 and older as deflator for the disposable income series.

terwar equations 1 and 2 and implies that, as an inferior good, coffee is being displaced by one or more beverages appropriate to higher per capita incomes, such as alcoholic beverages. Adult consumption of wine and distilled spirits has been rising in the postwar period; beer consumption declined slightly from 1947 to 1954 but is now back to the 1947 level.

It is difficult, however, to determine the role of alcoholic beverages in the coffee demand function for two reasons. First, distilled spirits and wine consumption are collinear with disposable income, the simple correlation coefficients being .88 and .93. Regressions substituting distilled spirits and wine consumption for income gave results similar to equation 5: highly significant negative coefficients.

Second, the interwar period as a beverage era is also sharply distinguished from the postwar period by the legal prohibition on alcohol in the twenties and early thirties. The repeal of prohibition came early in the thirties and while the long depression may have driven some to drink, it must have had a sobering influence on many others through the income effect. And, during World War II, there was rationing of liquor. Coffee consumption was thus, perhaps, unsustainably high at its maximum in 1946 because of the suppression of alcohol consumption in one way or another in the previous twenty-five years. The subsequent decline in coffee use may not have been causally related to the growth in per capita income but to the reappearance of a competitive commodity.[5]

These speculations do not affect the point of this note: that if income and relative prices are used to explain coffee consumption, the coefficient sign of the income variable is significantly negative (and remains negative under suggested adjustments). Whether the income variable is measuring very successfully the "income effect" is another question.

[5] The price elasticity in the postwar period was about half that in the interwar period. Assuming the demand function homogeneous of degree zero, the sum of the own-price, cross-price, and income elasticities is zero. Given the standard errors of the coefficients in the interwar period, the elasticities do sum to zero; they do not in the postwar period. A possible explanation is that in the text: that alcoholic beverages were not important in the demand function in the interwar period but were important in the postwar function. The price of alcoholic beverages was not included in either period, without consequence prewar but failing to provide a positive cross-elasticity postwar and biasing the income coefficient through the correlation of income and alcohol consumption.

Direct Payments: An Increasing Proportion of Farm Income and a Changing Geographic Distribution*

HAROLD D. GUITHER

AN earlier article [3] reported the distribution of direct government payments per farm and the relation of payments to realized gross and net farm incomes from 1933 to 1964. During the last five years, total direct payment expenditures have more than doubled [10, p. 64; 9]; and the cotton program, added to feed grains and wheat, has realigned the distribution among states, providing a new and more complex dimension for policy makers to resolve.

Payments per farm, as well as payments in relation to realized gross and net income, have also gradually increased (Table 1). In 1968, preliminary data show that payments were $3,485 million [10, p. 6].[1] With payments excluded, this was equal to 7.4 percent of realized gross and 30.7 percent of realized net income. The feed grains, wheat, and cotton programs accounted for 76 percent of all direct payments in 1965, 84 percent in 1966, 77 percent in 1967, and 83 percent in 1968.

Table 1. Average direct program payments per farm and payments as percent of realized gross and net farm income, 1964-68

Year	Payments per farm	Payments as percent[a] of:	
		Realized gross income	Realized net income
	dollars		
1964	634	5.4	19.6
1965	737	5.8	21.0
1966	1,012	7.1	24.8
1967	979	6.7	26.9
1968[b]	1,139	7.4	30.7

[a] Computed with government payments excluded. With payments included, payments as percent of realized gross would be 5.1 in 1964; 5.5 in 1965; 6.6 in 1966; 6.3 in 1967; and 6.9 in 1968. Payments as percent of realized net from 1964 to 1968 would be 16.7, 17.6, 20.2, 21.6, and 23.4, respectively.

[b] Preliminary.

* The author expresses appreciation to R. G. F. Spitze and Earl R. Swanson for reviewing an earlier draft of this paper.

[1] The 1968 preliminary figure reported in [11] was $3,485 million; the total reported in [9] was $3,475 million.

HAROLD D. GUITHER *is associate professor of agricultural economics, University of Illinois.*

With the high public interest[2] in direct payments at the present time, it seems appropriate to note the changes occurring and the distribution among the states and to assess the reasons for these changes.

The uptrend in payment per farm from $634 in 1964 to $1,139 in 1968 can be attributed partly to the 11 percent decline in farm numbers (from 3.442 million to 3.054 million) [13], but mainly to the 16 percent rise in payments [11, 12].

The continuous increase in payments as a percent of realized gross income from 1964 to 1968 is due primarily to increased payments, since realized gross income rose each year except 1967. Realized net income declined from the previous year in 1967 and 1968 so that both increased payments and a smaller net have helped to boost the percentage relationship of payments to net income.

In 1968 payments per farm varied among the states from $74 in Rhode Island to $7,322 in Arizona (Table 2).[3] Compared with the 1963 distribution and rank among states in payments per farm [3], the 1968 figures show the impact of the cotton program among the top 15 states. Arizona, New Mexico, Texas, California, and Mississippi moved up to higher rank than they held five years earlier. Rhode Island and other states with low payments outside the feed, wheat, and cotton producing areas, received most of their payments under the Agricultural Conservation Program.

More satisfactory indicators of the importance of change, however, are payments measured as a percent of realized gross and realized net incomes [3, p. 224]. In 1968 payments varied from .3 percent of realized gross income (excluding government payments) in Rhode Island to 19 percent in North Dakota. In terms of realized net income (excluding payments), payments varied from 2 percent in Massachusetts to 113 percent in North Dakota.[4]

Payments under feed grains, cotton, and wheat programs also show wide variations. Under the 1967 feed grain program,[5] payments were

[2] Some typical public reactions reported in the press and expressed in editorial comment are "Rich Get Richer," *Time* 89:19, June 30, 1967; "It's Time to Turn the Farmers Loose," *Fortune* 74:140–5, Dec. 1966; "A Possible Practical Utopia," by John Fischer, *Harper* 233:16, July 1966; "Farm Follies," *Reporter* 37.16, Sept. 21, 1967; "Findley Raps High Farmer Subsides," Robert A. Hunt, Associated Press story, March 15, 1969.

[3] Grove [3, p. 225] points out the close correlation between average payment per farm and payments measured as a percent of realized gross and realized net income and indicates that the wide variation in payments per farm among the various states is not due primarily to variation in size of farm but reveals a real difference in the incidence of direct payments among the states. However, Arizona, with its very large farms, may be an exception to this general relationship.

[4] Alaska's average payment per farm was $393 and its realized net per farm, including the payments, was $248 [11]; without payments, realized net income would have been a loss of $145. In 1967, payments were equal to 35 percent of net income; in 1966, 16 percent.

[5] 1968 figures not available at the time of writing.

Table 2. Comparisons of direct payments by states

State rank	1968 payments per farm[a]	All payments as percent[b] of:		Commodity program payments—1967[c]		
		Realized gross income	Realized net income	Feed Grains	Wheat	Cotton
	dollars			*percent of value*	*percent of cash marketings*

(Footnotes for Table 2 appear on following page) equal to 13 percent of the gross value of corn, grain sorghums, barley, and oats produced.[6] Payments to wheat program participants equalled 35 percent of total cash receipts from marketings; to cotton participations, 98 percent of total cash marketing receipts.[7]

In terms of value of production, feed grain payments ranged from less than one percent in New England and the Far West to 50 percent in Mississippi.[8] Wheat payments ranged from 8 percent of cash receipts in Florida to 79 percent in New Mexico. Cotton payments varied from 51 percent of cash marketing receipts in New Mexico to 1679 percent in Virginia. Although 1967 was an exceptional year, cotton payments exceeded receipts from marketings in 13 states.[9]

The differences among the states depend to a large extent on whether farmers in any given state can take advantage of cotton, wheat, or feed grain programs.[10] Obviously, those who have the most land and the largest bases can retire the most land and collect the largest payments.

States at the fringe of the major producing areas often have larger payments in relation to the value of production than in the higher producing states. Feed grain payments were relatively highest in the east, the northern fringe of the corn belt, and in the southeastern and southcentral states. Cotton payments were relatively highest in the states just north of the main cotton belt. This pattern indicates that direct payments offer a higher economic incentive than production in these areas.

The distribution pattern also shows that those states with highest payments in relation to income are those where one or more of the commodities with programs offering direct payments make up a sizable portion of

---

[6] Calculated on the basis of total production and average price received in each state for corn, barley, grain sorghum, and oats. Total value was used rather than cash receipts from marketings because about 45 percent was used on farms where produced.

[7] The proportion was 3 percent in 1965; 69 percent in 1966. Total payments for 1968 were $787 million, indicating that the 1968 percentage will be close to 1966.

[8] Low states were New Hampshire, Massachusetts, Rhode Island, Connecticut, Nevada, and California. Mississippi appeared unusually high because of an apparent shift of feed grain base acreage into soybeans, permitted under ASCS regulations.

[9] Illinois, Missouri, Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Tennessee, Alabama, Oklahoma, and Texas (see Table 2).

[10] Exceptions: Hawaii, Florida, and Louisiana, which in 1968 received payments from the sugar program of 98, 33, and 21 percent, respectively; 17 percent of Wyoming payments came from the wool program.

---

[a] Calendar year total of direct payments divided by number of farms estimated by Statistical Reporting Service, USDA.

[b] Calculated with payments excluded from realized gross and realized net incomes.

[c] 1968 data on receipts from marketings by states were not available at time of writing; calculated with calendar year payments by commodity program divided by value of production of feed grains and cash marketing receipts of wheat and cotton, by states.

[d] See footnote 4.

Sources: [9, 11].

the cash receipts from farm marketings. In states with more diversified production, payments provide a relatively less important contribution to farm incomes.

Attempts to reduce support levels, acreage in land retirement, or direct payments would reduce the total program costs. But the net effect would be a reduction of transfer payments from the public to the agricultural sector and require economic adjustments for many farm operators. The shock would be less severe if adjustments were made over several years rather than all at once[4]. The above data indicate that cotton and wheat producers would be most seriously affected.

The Senate inquiry into direct payments [8] showing that 36 percent of the 1967 payments totalling $1.1 billion were distributed as payments of $5,000 or more, along with the Report on Rural Poverty [1, 5, 6], was largely responsible for the attempt to limit payments when the Agricultural Act of 1965 was extended in 1968. In future hearings Congress will likely be more responsive to the "needs of men rather than of land and commodities" [7, p. 1117].

On the other hand, will limitation of payments, to $20,000 or some other "reasonable" figure, accomplish the objectives sought? Or will it merely stimulate new leasing or tenure arrangements between landowners and tenants and a reshuffling of payments with other sharing of costs and returns to achieve compliance with the law? Further study and a trial period of program limitations may be necessary to answer these questions.

Nevertheless, the predicted time may be at hand when "farm program costs are headed for a direct collision with budget limitation objectives of the urban voter" [2]. Congress and the new administration in Washington may unconsciously follow the words of the late President Franklin D. Roosevelt, spoken in Brooklyn, New York, in 1940: "The test of our progress is not whether we add more to the abundance of those who have much; it is whether we provide enough for those who have too little."

ON SCIENTIFIC OBJECTIVITY: COMMENT

In a recent article in this Journal, Breimyer [6, p. 350] states that "unless agricultural economists in all forms of employ meet *all* the tests of a scientific discipline, including the test of objectivity, agricultural economics cannot wear the esteemed toga of a science." In accordance with this statement, Castle in his article [7] tries to classify the significance, meaning, and implications of scientific objectivity. Basing his approach toward objectivity on Karl Popper's famous and fundamental definition, the Popper-criterion [18], Castle tries to demonstrate the requirements that must be met by scientific research work in agricultural economics and farm policy as well as in all other parts of science. However, we believe he has made some fundamental misinterpretations and misunderstandings of the scientific process of discovering the truth.

1. Although he bases his argument on Popper, Castle nonetheless creates the impression, firstly, that personal objectivity is possible and permits one to reach unbiased results and, secondly, that such objectivity is constitutive for science.

Although he remarks initially that "the method is an impersonal one" [7, p. 809], yet the following argument sets out to show the threats to the "objectivity" of the individual whose "short-run individual self-interest . . . is not always enhanced by objectivity"[7, p. 810]. To assume that "objectivity is in the public interest" is to camouflage still further the underlying problems connected with the concept.

2. Today we know that objectivity in the "reine Vernunft" (pure reason) sense is no longer realizable as a voluntary act; that, on the contrary, every attempt to gain knowledge and solve problems is interwoven into the fabric of their sociocultural surroundings. Consciously or unconsciously, every effort is exposed to sanctions to conform—pressures that more or less prescribe standards of problem-solution. "Die Vernunft in jeder Gestalt ist ein sozialkulturelles Zuchtprodukt auf vitaler Grundlage"[1] [2, p. 93; cf., also, the references mentioned here].

3. It is thus evident that an indi-

---

[1] Reason in every form is a social and cultural product cultivated on an ever-changing foundation.

vidual cannot achieve his aim to ascertain an objectively valid view of reality and its potentialities [cf., also, 19, p. 267]. Objectivity in this sense cannot be constitutive for the concept of science. Instead, as a prerequisite for the functioning and validity of science, there must be a "Kommunikationsgemeinschaft" [3, 4], i.e., a circle of researching scientists in communication with one another. This circle would reach a consensus on a minimal norm, roughly in the manner presented in Popper's postulated critical rationalism, which implies intersubjective cross-examination and access to such critical examination [1, 19, 20].

Scientific objectivity thus becomes not the result of the isolated individual's striving for impartiality "but a product of the social or public character of scientific method; and the individual scientist's impartiality is, so far as it exists, not the source but rather the result of this socially or institutionally organized objectivity of science" [19, p. 220].

4. Since Castle maintains that "individual altruism is a shaky foundation on which to base objectivity" [7, p. 810], why does he concern himself —as he does superficially anyway— with threats to this type of personal objectivity instead of examining those social institutions that are the *sine qua non* of science (places of scientific research, magazines, scientific conferences) and their potential to guarantee general accessibility to scientific work and intersubjectivity as a permanent form of criticism?

5. If we assume—as Castle does—that "objectivity is in the public interest" [7, p. 810] and if we suppose that the public interest is represented by ruling elites (cf., for example, the political theory of Schumpeter [22]), then there is no reason to assume that the scientific institutions should not also be organized with the goal of maximal objectivity. And in fact there are plenty of examples that can be quoted—at least in the domain of our technical knowledge (including social technology)—which succeed in keeping a minimal standard of intersubjective cross-examination [21, 23, and the references given there]. This they do by striving for the greatest possible "Wertfreiheit" within their system of declarations, that is, in the domain of their "Objektsprache" where value-free statements are possible. Not to achieve this norm is in effect to exclude oneself from the process of science.

6. But if science is to avoid becoming an ideology[2] [10, 11], it cannot simply be viewed as a "handmaiden to policy" [6, 14], devoted to making possible "zweckrationales Handeln" (rational behavior for the object in view) in Weber's sense of that term [24, 25] if, at the same time, it abandons critical communicative action and thereby permits irrational decisions ultimately to become dogmatized [2, 8, 9].

If science is to be more than a legitimizing instrument of authority, it must overcome the positivistic dualism of knowledge and decision-making,[3] i.e., it must enter a critical interdependence relationship with policy-making. And while serving toward the solution of technical questions, science must also adopt an "emancipatory interest in knowledge" [9]. A successful transference of technical and strategic recommendations into practice is thereby referred to the mediation of the public [9, p. 129]. That is, a critical interdependence relationship between science and policy-making within a democratic framework is connected to and dependent upon a communicative feed-back with an enlightened and self-conscious public.

---

[2] Ideology in the sense of a social doctrine of justification (a "Rechtfertigungslehre").

[3] We cannot here go further into the differences between the conceptions of a revised positivism (Popper; Albert) and representation of the so-called critical theory (Adorno; Habermas) [cf., for example, 25]. But just recently a certain convergence can be noticed.

7. It is evident that under present-day circumstances criticism of ideology and aims is, as a rule, at variance with the so-called public interest represented by elites. That is, the autonomy of scientific institutions is permanently threatened.

It has to be asked to what extent such autonomy still exists today in concrete terms; and these doubts are nourished by the present "university crisis" to be seen the world over [12; cf., also, 15 and 16] which to a large extent can be interpreted as a protest —coming in the main from students —against the intrusion of sectarian ideologies, disguised as "public interest," into the sphere of science.

8. Even if one were inclined to admit that "objectivity is in the public interest"—which, as said above, is doubtful enough—there is, however, no criterion for objectivity that could enable the scientist "to formulate and advocate a position on a particular policy at a point in time" [7, p. 810]. We are always lacking significant and necessary information [5], and even if this were available, it will prove impossible to transform such information into a consistent system for operational action in economic policy [13].

Instead of justifying actions of policy, there thus arises the need to question critically and rationally every dogmatized standpoint of science and of policy.

The prerequisites for this are, of course, (a) that the scientific process run its course in unlimited material and ideal freedom [2, p. 173], for only in this way can the prerequisite be created for the intercommunicative process of discovering the truth; and (b) that the public be brought without impediment into the interdependence relationship between policy and science so that the latter may exploit its controlling function with regard to the application of the technologists that science puts at the disposal of policy.

9. And, finally, a remark of a more general nature: Time and time again the European observer is struck by the fact that Castle's criterion for intersubjective cross-examination of scientific theories, mentioned at the outset, is frequently impaired in this Journal by the failure of authors to discuss and to accept scientific knowledge—even in the field of epistemology—which is formulated in any language other than English.

ON SCIENTIFIC OBJECTIVITY: REPLY

I am grateful to Schmitt and Timmerman for their comment on my article [1]. I am in basic agreement with them, even though they do not seem to believe they are in agreement with me. In any case, their comments permit discussion of several subjects that were eliminated from an earlier draft of the article. Our profession has neglected issues of this type, and I would be pleased if this Journal were to become a focal point of such discussions in the future.

1. Schmitt and Timmerman's final point may well be their most important. Comments and original articles by Europeans and others who draw on the non-English literature will add strength and new dimensions to the Journal. Readers will appreciate their list of references; some of these were not familiar to me, even though I do not believe their methodological arguments are substantially different from the position on which my article is based.

2. While my article may be misleading because of its brevity, it was based on the same methodological position regarding individual objectivity as stated by Schmitt and Timmerman. However, I believe Schmitt and Timmerman fail to grasp two fundamental points:

a. Even though "scientific results" depend on the process of science rather than individual objectivity, the individual research plays a role in that process. Unless the conditions are present so that he can pose refutable hypotheses, test these in an appropriate fashion, and subject his method and results to scrutiny, meaningful replication cannot occur. And, if meaningful replication cannot occur, we will never achieve "a consensus on a minimal norm, roughly in the manner presented by Popper's postulated critical rationalism, which implies intersubjective cross-examination and access to such critical examination" (Schmitt and Timmerman). The section on "Threats" in my article was an attempt to illustrate the relationship between socio-cultural surroundings and attempts to gain knowledge.

Part of the difficulty in communication may result from the failure of Schmitt and Timmerman and myself to point out that objectivity can never be measured by an absolute standard if one takes into account the source of the hypothesis. I call particular attention to the last paragraph and footnote 7 in my original article [1, p. 813]. It is always possible to develop alternative hypotheses about the same phenomena. If Schmitt and Timmerman are saying we should move in and out of particular analytical frameworks in developing alternative hypotheses, I take my stand with them on this also.

b. Economics as a science has not yet progressed to the point where replication and cross-examination of another's work will automatically lead to a consensus. Under these circumstances, we all need to identify our value judgments and make them as explicit as possible. This is a necessary step in reaching consensus. If the "Threats" section has value, it is in encouraging economic researchers to be more aware of the source of such possible values.

3. Another fundamental point pertains to my tentative assumption that scientific objectivity is in the public interest. I accept the criticism. As a matter of fact, in the original manuscript I discussed this subject at some length under the heading of "Economics and Objectivity." The elimination of this section created confusion. However, the foundation of my article is the position taken by Schmitt and Timmerman that there are no settled questions in science. I agree that a person who takes a policy position may be taking "rational behavior for the object in view" (Schmitt and Timmerman), and is not, in that case, acting as a scientist. Nevertheless, there is obvious hazard of doing that

in the public arena while attempting to retain sufficient flexibility to embrace additional information, when this additional information may indicate a different course of action to be more rational. A careful reading of my article will show that I believe the "public interest" to be an unworkable criterion, given the present state of the arts. It was for this very reason the article was written; I did not believe that only research undertaken under the heading of enhancing the "public interest" should be classed as scientific. I call particular attention to footnote 6 in my article, as well as the concluding sentence.

4. Finally, I again express my appreciation to Schmitt and Timmerman for extending my article in a useful direction. When my article was submitted for publication, I devoted considerable space relating the considerations discussed by Schmitt and Timmerman to that part of my article which was eventually published. It was suggested by the reviewers the article should be shortened to "Communication" length and I attempted to comply, even though the manuscript was eventually published as an article. In retrospect, I believe I should have insisted on the length of the original manuscript, because the type of misunderstanding that resulted could have, in large part, been avoided.

U.S. IMPORT DEMAND FOR GREEN COFFEE BY VARIETY: COMMENT

Abaelu and Manderscheid have investigated an interesting topic [1], but their results are less informative than they seem to realize and much less useful than they might easily have been.

1. The decision to use only Colombian imports to represent milds ("U.S. demand for milds is measured by U.S. coffee imports from Colombia, the biggest producer" [1, p. 236]) was unfortunate and clearly improper on their own description: "While Colombia supplies the bulk of world requirements for milds, other important sources of this coffee variety in the western hemisphere include El Salvador, Guatemala, Costa Rica and Mexico" [1, p. 232].

Equation (1) on p. 237 and p. 239 is, therefore, *not* the import demand function of the U.S. for milds but the import demand function of the U.S. for Colombian milds. "Other milds" were imported by the U.S. in slightly smaller amounts than Colombian milds in 1953, and if the approximate equality had held, there would have been no problem; but, in fact, the ratio of Colombian milds to other milds declined through the period from about 1.1 in 1953 to about .7 in 1961 [2, pp. A 106–7]. There was, therefore, no linear relation by which the coefficients of the total milds import equation could be calculated from the coefficients of the Colombian milds import equation.

Either the other milds should have constituted a separate category or the Colombian and other milds combined into a total mild aggregate and a price index for the group calculated.

The separate category procedure is clearly preferable. It was not made clear in the article that coffee is classified by the International Coffee Organization into two principal groups, arabicas and robustas. The arabicas are subdivided into Colombian milds, other milds, and unwashed arabicas (Brazils).[1] If four, rather than three categories were used, then a generally closer price substitute than Santos 4 could have been used for Colombian milds, i.e., prices of other milds, such as El Salvador Central Standard, Guatemala Prime Washed, and Mexico Prime Washed.

2. Similar objections can be made to the Robusta and Brazils equations. Imports from Angola and the former French West African territories, used by Abaelu and Manderscheid to represent total U.S. demand for Robustas, were 79 percent of all Robusta imports in 1953 but were down to 54 percent by 1963 and to 49 percent by 1966 [2, pp. A 108–9].

For the Brazils, the problem was much smaller, since Brazil dominated the category, but yet the ratio of imports from Brazil to total imports of Brazils varied from 98 to 92 in the sample period [2, pp. A 106–9], causing at best errors of observation seemingly unnecessary since only Bolivia and Ethiopia need be added to have the entire category accounted for.[2]

3. The data defects caused by using "representative" countries rather than the actual totals may also be involved in the poor performance of the export supply and stock demand functions for each category (of the fifteen variables used in equations 2, 3, 5, 6, 8, and 9, only one was significant by the usual standards). Abaelu and Manderscheid estimate the quantity of each variety in total stocks "[by] multiply[ing] total stocks by a number representing the proportion of that variety in total coffee imports in the current quarter" [1, p. 236]. Without reference to its theoretical validity, this procedure does not work because the proportion each representative group is of the total of representative imports does not correspond to the proportion actual imports of that category bear to the total of actual imports. For example, in 1961 the comparable proportions for milds were .28 (Abaelu and Manderscheid) and .44 (actual); Brazils, .59 and .41; and Robustas, .13 and .14[3]

---

[1] In the first years of the International Coffee Agreement, the Colombian milds and the other milds were combined into a single 'mild' category and the price of milds were calculated by averaging the three cited prices and then averaging that mean with the price of Colombian milds. The second procedure suggested would thus use the initial coffee classification of the International Coffee Organization.

[2] The regression of Brazil's annual share on time was $\underset{(-1.94)}{94-.28t}$ for 1953–61 and $\underset{(-3.96)}{94-.70t}$ for 1953–66, where the expression in parentheses is the t-score.

[3] The example is representative. The closest approximations were in 1953: milds, .41 (Abaelu and Manderscheid), .56 (actual); Brazils, .53 and .58; and Robustas, .07 and .06 [2, pp. A 106–9 and A 86].

4. Abaelu and Manderscheid conclude from the sign of the income coefficients in their import demand equations that Colombian milds is a normal good (sign positive) and the Brazils and Robustas inferior goods (signs negative). "Other relevant factors remaining constant, further growth in the U.S. per capita disposable income should boost the demand for milds in the United States" [1, p. 240].

The cited evidence from the Colombian milds equation is not persuasive, the income coefficient being positive but no larger than its standard error. Other evidence, of the kind predicted by Abaelu and Manderscheid, is against the normal classification. Both the quantity and the share of Colombian milds in all coffee imports declined (significantly) from 5,606 thousand bags (27 percent of all coffee imports) in 1953 to 2,716 bags (12 percent) in 1966 [2, pp. A 106–7 and A 86], surely not the quantity behavior expected of the only normal variety in coffee.[4] Moreover, the share of Colombian plus other milds in total coffee imports also declined from 51 percent (1953) to 39 percent (1966) [2, pp. A 106–7 and A 86].

In comparison, the total imports of Robustas were 856 thousand bags in 1953 and 4 percent of total coffee imports. The imports of this inferior variety rose steadily to 5,964 thousand bags in 1966 and 27 percent of total imports [2, p. A 86].

Abaelu and Manderscheid are conscious of some interpretative difficulties: "Because of high intercorrelation with income, the trend variable was dropped. Thus, the model might attribute the effects of technological progress and changes in consumer taste to the income variable" [1, p. 240]. It is, therefore, all the more surprising that they did not use the wealth of annual, quarterly, and monthly information on coffee in the entire postwar period to provide better estimates and stronger findings.

Certainly, their reason for not using the later data is weak: "The period subsequent to 1961 was excluded because of the International Coffee Agreement, which is believed to have caused extensive changes in the conditions underlying coffee marketing" [1, p. 236]. International control of coffee supplies to achieve price objectives will add another argument to the supply function but is irrelevant to the import demand function. And, given the poor results achieved in all the supply equations for 1953–61, there would have been little to lose on supply and much to gain on demand by extending the sample period as far as possible.

JOHN J. HUGHES
Boston University

---

[4] The price of Colombian milds increased relative to Brazils from 1953 to 1961, but not over the entire period 1953–66 [2, pp. A 130–1].

U.S. IMPORT DEMAND FOR GREEN COFFEE BY VARIETY: REPLY

Professor Hughes has made a number of suggestions worthy of consideration in any extension of the earlier study by John Abaelu[1] and myself. On the other hand, his conclusions require tempering. When our study was conceived, we were unaware of published statistical studies of coffee demand that attempted either to differentiate varieties of coffee or to study the demand-supply interaction in the market. Rather, most previous attempts concentrated on total coffee demand. One of our major objectives was testing whether or not the several varieties behaved differently in the market. Professor Hughes concedes implicitly that we found differences by suggesting further disaggregation. Certainly our attempt should not be thrown out because it does not disaggregate enough, unless either the results are incorrect (or misleading) or one has a better alternative.

The specific objections raised by Professor Hughes in points 1 through 4 are worth serious consideration for future studies. We were not unaware of these objections—but they are not as serious for our sample period of 1953–61 as they are for longer periods suggested by Professor Hughes. New studies should not only consider the International Coffee Agreement in the supply equations but should also include other policy variables such as export taxes. Professor Hughes could also have pointed out that coffee from any one country is not homogeneous within a year nor is the average quality homogeneous over time. Therefore, neither use of representative prices (of a single grade) nor of total quantity (without reference to quality) is completely valid; both are approximations useful for many purposes.

There are other deficiencies in our study; hopefully, someone will accept the challenge to do further work in the area.

LESTER V. MANDERSCHEID

THE EFFECT OF A MARKETING ORDER ON WINTER CARROT PRICES: COMMENT

In the November 1968 issue of this Journal, Professor Carl E. Shafter [1] examined the effect of a marketing order on winter carrot prices. We wish to suggest that there are some logical inconsistencies in his paper that appear to arise out of improper specification, and hence the conclusions inferred from the statistical results were not warranted. Instead, we wish to submit our own hypotheses, quite opposite to those of Shafer's, and contend that our explanatory hypotheses are more reasonable—at least from the standpoint of traditional microeconomic theory—and that his statistical findings are not inconsistent with our postulates.

We are indebted to G. Edward Schuh for encouragement and helpful comcomments.

First, we summarize some of the important observations made by Shafer:

1. Before the imposition of a marketing order in Texas in 1960, Texas and California both produced winter carrots and competed in several markets throughout the U.S. with the relatively low quality Texas carrots receiving the lower price.

2. After the imposition of the marketing order, which had the effect of narrowing or eliminating the quality differential between Texas and California carrots, it was seen that (a) there was a convergence between the prices of carrots from the two areas, and (b) a convergence between the grower price and the f.o.b. price, or the price received by shippers, in Texas.

To explain the price behavior between pre- and post-order periods, Shafer offered two hypotheses:

1. The imposition of the marketing order had the effect of making Texas carrots more comparable in quality to the California carrots and thus increased the demand for Texas winter carrots, raising their price, and narrowed the price differential between the two areas, as indicated by terminal market prices.

2. The advent of the order and the resultant improvement in the quality raised the derived demand faced by Texas growers while leaving the demand curves at the shipper level unchanged thus bringing about a convergence of grower and f.o.b. prices in Texas.

An examination of the above hypotheses reveals that Shafer utilized a demand-biased model to explain observed price behavior. We wish to suggest, instead, that a supply-biased model is more relevant insofar as the effect of the marketing order would primarily be on supply rather than on demand.[1] For unless one is willing to accept the hypothesis that a market order alters the utility functions of the final consumers and hence shifts their aggregate demand for carrots, there is no reason to expect shifts by the derived demand curves at the grower and shipper (f.o.b.) levels.[2]

In what follows, we shall take Shafer's price observations as given and offer likely alternative hypotheses of our own. We do not claim that ours are the true explanations. Instead, our aim is to show how a supply-biased model might explain the same observation. We shall make only those assumptions that yield the simplest and most clarifying explanations while noting that more complex assumptions would change the magnitudes of the results but not their substantive relations. Finally, we shall point out important differences in policy implications to be deduced from our model vis à-vis Shafer's.

For our model, we shall first redefine our market for carrots. Instead of having only Texas carrots and California carrots, we also explicitly differentiate between high quality carrots and low quality carrots. By so doing we are adding additional demand and supply considerations which we feel are helpful for a clear explication (below) of the price and market order relations.

First, we assume the existence of two final market demand curves—one for high quality winter carrots (D_h) and one for low quality winter carrots (D_l). Similarly, we have two supply curves (S_h and S_1). For the sake of simplicity we assume the supply

---

See also [2].

Except as indicated below. See footnote 3.

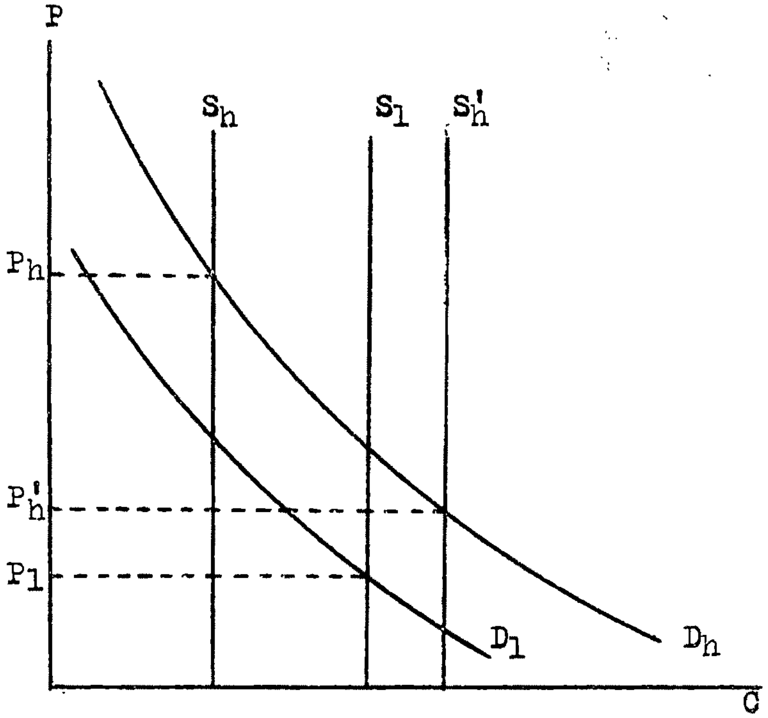

Figure 1

curves to be zero elastic. Finally, assume that prior to the order all the carrots supplied by California were high quality carrots and those supplied by Texas were low quality carrots; and after the order, both states supplied only high quality carrots. The explanatory hypothesis about the convergence of terminal Texas and California prices can be inferred from Figure 1.

Prior to the order, the price of California winter carrots was P_h and that for Texas was P_1. After the advent of the order, we have only one supply curve for carrots (S_h') which is the summation of the California and new Texas supplies. The price now received for both Texas and California winter carrots are P_h' and hence demonstrates the convergence of terminal prices for carrots from these two areas.

It is important to note that the effect of the order was on supply and not on demand. The order altered the market for carrots from a two-commodity (high and low quality carrots) to a single commodity (high quality carrots) market. The demand curves remained unchanged since there appears to be nothing inherent about a market order that alters the preference functions of the final consumers and hence their aggregate demand.[3]

---

[3] It is possible that final demand for high quality carrots may have changed [see 2, p. 1362] as a consequence of either a reduction or elimination of low quality carrots from the market. That is, if low and high quality carrots are substitute commodities to the final consum-

If the final demand for winter carrots did not shift after the imposition of an order in Texas, what would cause the derived demand facing the Texas growers to rise as postulated by Shafer? On the other hand, if the final demand did change, then the change will alter the f.o.b. demand as well as the demand faced by growers. But by stating that the f.o.b. demand was unaffected by the order, Shafer would be hard put to explain why the derived demand facing the growers increased. In short, there appears to be some inconsistency in his model. Yet, unless he could make claim to an unchanging f.o.b. demand as well as a changing derived demand facing growers, he would be unable to explain the convergence between grower and f.o.b. prices.

Again, we suggest that it is more fruitful to examine the problem from the supply side. It is possible that one of the effects of the marketing order is to alter the competitive character of the market structure at the grower level [2, pp. 1362–1364]. In the extreme, it changes the market from one of many small sellers to one of a single large seller. The result is that it alters the bargaining strength of the Texas growers vis-à-vis the shippers. And since the competitive structure of the shippers' market is unaffected by the order, the growers, with increased power, may gain at the expense of the shippers through the reduction of the margin between grower and f.o.b. prices.

We have offered two alternative hypotheses here about the price observations made by Shafer. To reiterate, we do not claim that ours are the true explanations. Instead, what we have argued is that a supply-biased model is more reasonable than a demand-biased model for the explanation of the effects of a marketing order. The statistical results presented by Shafer are not inconsistent with our postulates.

More importantly, whether the effects of a marketing order are on the supply side or on the demand side has profound policy implications. For instance, it has often been argued that marketing orders should be imposed in order to raise the income of farmers. Indeed, if a marketing order could raise demand, it becomes a powerful means of raising the level of farm income. On the other hand, if it operates primarily through supply shifts, its effects on farm income would depend on the elasticity of demand. Since demand for carrots is probably elastic, the effect would most likely be to *reduce* income (gross) to the farmers. This might explain why the Texas carrot growers voted out the order after a brief trial.[4]

H. PRESCOTT BEIGHLEY
JAMES MAK
Purdue University

---

ers, the elimination of one may alter the demand for the other. For instance, one might postulate that the demand for high quality carrots may become less elastic. But if there is indeed an alteration of demand on the part of the consumers, it is the result of the order's effect in changing the composition of goods supplied. Moreover, if the demand is changed in the final market, similar effects will be evidenced in the derived demands at the f.o.b. and the grower levels. Shafer, however, denied that the f.o.b. demand was changed by the order, from which we inferred that the final demand did not shift. In any case, even if we allowed a shift in the final demand, the price received for Texas and California carrots after the order would be the same, since the order eliminated the supply curve for low quality winter carrots.

[4] We thank G. E. Schuh for raising this point.

THE EFFECT OF A MARKETING ORDER ON WINTER CARROT PRICES: REPLY

First, let me correct an error brought to my attention by Mark Fowler as this may help in discussing Beighley and Mak's comment. In the paper in question, a hypothesis is presented that the derived demand for Texas winter carrots shifted upward and to the left during the order period [1, pp. 879, 886], an obvious contradiction which interpreted literally means the derived demand shifted up (or right) *and* left (or down). My error. The reference to a leftward shift in the derived demand may be cleared somewhat but certainly not absolved by correcting the typographical error in the last line of the second paragraph on page 886 which should have read, "The latter or volume effect is essentially a movement along the higher demand relation." rather than ". . . a movement along with the higher demand relation." Such movement to the left along the higher demand relation would, in effect, be a drop in supply since more stringent grading would be expected to reduce the proportion of total production actually shipped or sold. This supply effect or reduction in the proportion of the crop actually sold was not evaluated in the paper.

The hypothesis that the derived demand for Texas winter carrots did shift upward or to the right was based on (a) improved quality due to more stringent grading and (b) an undifferentiated reference to ". . . the possible effects of any of the several market organizing features of an order" [1, p. 881]. The next sentence in the text suggests that the order was responsible for the reduction of market imperfections within the supply area and refers implicitly, in part, to a possible increase in the bargaining power of growers (in-field level) vis-à-vis shippers (f.o.b. price level).

Although Beighley and Mak's comments forced me to examine the paper from another perspective—the supply-biased model—I will argue for the "demand-biased" approach. In terms of microeconomic theory Beighley and Mak are correct in that this was not a shift in demand as traditionally associated with changes in (a) the prices of related commodities, (b) income and/or (c) tastes and preferences of consumers. Insofar as improved quality was responsible for higher prices at the grower level,[1] the higher demand relation would, as Beighley and Mak state, be for a different commodity; i.e., higher quality carrots. However, the extent that the higher demand relation was due to the improved bargaining position of the growers vis-à-vis the shippers would be due to an upward shift in derived demand. Such a "shift" would be possible because of "imperfections," in the market, which the "market organizing features" of the order may have both illuminated and, to some extent, removed. I accept Beighley and Mak's hypothesis that the marketing order might "alter the competitive character of the market structure at the grower level." In fact, I believed that I had included the same reasoning, although perhaps too thickly veiled, as support for the "demand shift" hypothesis.[2]

---

[1] Improved quality at the grower or field level could have been due to increased field grading as mentioned on page 885 of the article.

The partial point price flexibilities for Texas growers for the eleven years computed from Table 1 of the paper varied from −0.52 (1954) to −3.18 (1960) with the price flexibility at the means being about unity. This meager evidence suggests that Texas growers would at least be interested in avoiding large crops because of the associated decreases in gross returns. However, in addition to the partial price flexibility associated with quantity, the price flexibility associated with quality (price response to improved grade of commodity) is also relevant in considering the total returns position of the growers as was discussed briefly in the last paragraph of the article.

The South Texas carrot order was voted out in April of 1966 largely due to high prices, short supplies, and the administrative committee's unwillingness to reduce the length of carrots eligible for consumer cello packs. The order committee was using size requirements in an attempt to regulate supply. However, this technique discriminated against the relatively high rainfall areas in that many carrots from these areas did not meet the minimum length requirements. One thing led to another, including some element of the grower-price—shipper-volume conflict, and the order was defeated.

FOOD DONATION PROGRAMS

Food donation to low income families illustrates the principle that the shortest political line between two points is a jagged one. Such a line can touch the most areas of support and detour part of the opposition. However, a program so contrived can also confound analysts, both friendly and hostile.

Food donation began as much to relieve the federal government of embarrassing farm surplus as to help recipients. It has been progressively directed toward the latter objective. Throughout, the program has been kept separate from public assistance.

Consistent therewith, food donation has come to be justified in terms of relieving malnutrition. It is tested in the publicity crucible on the grounds of how effectively it does so. Once it was vilified as giving too little, or too plain, food. John F. Kennedy's West Virginia campaign led to quick correction after he became President. A common charge now is that the program reaches too few.

Another current objection is of different timbre. Critics with welfare orientation oppose aid in kind. They want dollar aid only, which, less paternalistic, lets families balance food with other needs.

In large measure this second debate is semantic exercise. Families receiving donated food are able to incorporate that income-in-kind into their total expenditure pattern. That is, they have a wide range of choice as to the extent to which they substitute that food for their normal food purchases, thereby freeing dollars for discretionary use. In this respect food received becomes the equivalent of ordinary income.

This is true for families that previously were not destitute—that made substantial expenditures. It is true so long as donations are modest in scale and the kinds of food received do not clash with families' food tastes.

These basic issues underlay a study of the Commodity Distribution Program in Harrison County, Missouri, made in the summer and fall of 1967 [1]. The distinctive feature of the study was that it straddled initiation of the program: families eligible to receive food were surveyed before distribution began and again three months after it was instituted.

Most trenchant finding was the high degree to which families substituted donated foods for their pre-program purchases. That food donation would have this consequence has often been alleged, but this study is one of the rare instances where empirical data are citable. In Harrison County substitution appeared to be essentially total; but before data are converted to dogma, possible inaccuracies must be noted. Families are clearly inexact in their reporting; for example, diary data for food expenditures under the program exceeded memory estimates by 40 percent. Seasonality and opening of school impeded precise reporting.

More meaningful and trustworthy are differences by kinds of participants. Families who spent most for food before the Program began were quickest to use donated food to save money. These were the largest families. Though much is written popularly about the destitute aged, in Harrison County the low-income younger families with children seemed to be in the tighter straits. To them, apparently, donated food was surrogate for shoes for kids. However, medicine was named as first claimant on freed funds and fuel second. Clothes were third.

Were diets left unimproved? Data from the study are sketchy, yet those collected seem to show some nutritional gain. Data assess adequacy of servings of food within each of four food groups. For three of the groups, a higher percentage of families showed an adequate number of servings after the program began than before. Only for one group did families slip back. Moreover, after food distribution began, about 59 percent of households receiving food met standards for two, three, or four of the groups, compared with 49 percent before the Program came to the county.

Thus, the burden of nutritional advancement is put on the quality of the foods distributed. Though families had previously not starved, neither had they enjoyed particularly good diets. Apparently, if donated foods are to enhance diets, they themselves must be nutritionally superior. It is not safe to rely on families using freed dollars to buy the nutritionally better foods.

Matching the findings of the study against social philosophy and principles of government is not easy. Obviously, justifying food programs solely in terms of feeding hungry or malnourished people contains sleight of hand, if not hypocrisy. But by the same token, thereby is denied the charge of paternalism. Donated food is indeed income-in-kind, to very considerable degree; the program allows much latitude as to the disposition of the dollar value of the food that families receive.

Then why not just give the families money? Though this might be the best policy, two counter-arguments carry weight. One is that the families do improve their nutrition to some extent, especially if good food is distributed. The second, a political one, is powerful: so long as the federal government accumulates surplus food, or so long as it sees total food production as excessive, it is far more feasible to win majority support for food distribution than for substantially increased welfare payments. This latter is not an irrelevant consideration.

Yet the most penetrating conclusion may be still different; it is that those families who must use any chance to save a few dollars in order to pay medical bills and to buy fuel and clothes are living on the brink of desperation, by any enlightened criteria. Further, within the class of the population qualifying for public assistance and food distribution lie a wide range of circumstances and highly varying degrees of need. Criteria for eligibility based on income alone (relative to family size) with a single, discrete cut-off line help to account for the varying degree to which donated food translates into better nutrition vs. income for paying non-food bills.[1] Food program experiences may also confound, yet partly correct, middle-class ideas as to the nature of a sizable separate world.

HAROLD J. LOYD
HAROLD F. BREIMYER

A COMMENT ON A TRADITIONAL BEHAVIOR MODEL

In an unnecessary controversy between Yotopoulos and Wise [3, 4, 5] and Johnson [1, 2], the reader of this Journal is given the following model of traditional behavior:[1]

$$H_0\colon \max U(R, C) = \log R - C = t$$

with the properties

$$\frac{\partial U}{\partial R} = \frac{1}{R} > 0,$$

i.e., diminishing marginal utility of revenue (or output) and

$$\frac{\partial U}{\partial C} = -1 < 0,$$

i.e., constant marginal disutility of cost.

Johnson [2, p. 209] has argued that this is a strange model because for plausible values of R and C utility is negative, and marginal disutility of cost is always greater than the marginal utility of revenue.

Yotopoulos and Wise [4, p. 209] disagreed with Johnson, pointing out that units of measurement are arbitrary and and therefore "plausible" values is an ambiguous term, and specify their model as

$$\begin{aligned} U(R, C) &= \log (aR) - (aC) \\ &= \log a + \log R - aC \end{aligned}$$

which has a maximizing equilibrium, since

$$\frac{\partial U}{\partial R} > -\frac{\partial U}{\partial C} \qquad \text{for } 0 < R < 1.$$

My comment is that this model, even adjusted for the unit of measurement, remains a strange one. The range of values of R for which the model has maximizing equilibrium is not $0<R<1$, but $0<R<1/a$, i.e., the range of values of R depends on the selection of a. For $R=1/a$,

$$\begin{aligned} U(R, C) &= \log a + \log \left(\frac{1}{a}\right) - aC \\ &= -aC < 0. \end{aligned}$$

For $R=1/ab$, where $b>1$ so that $0<R=1/ab<1/a$,

$$\begin{aligned} U(R, C) &= \log a + \log \left(\frac{1}{ab}\right) - aC \\ &= -\log b - aC < 0; \end{aligned}$$

that is, if the model is to have maximizing equilibrium, then U is negative. Since $-\log b - aC < -aC$, at $R=1/a$ the firm is minimizing negative utility.

The conclusion is that even in this general formulation the traditional model proposed by Yotopoulos and Wise cannot be considered as a rival model to profit-maximization and/or fixed proportions models.

EPILEGOMENA ON TRADITIONAL BEHAVIOR MODELS

The comments raised by our empirical formulation of the model of traditional behavior [1, 2, 3, 4] indicate that sight of the forest has been lost for the trees. In a way of clarification, we apply the hatchet on the trees that have confused Dr. Lianos by formulating the model in its general form.

(i) Our traditional model specifies a utility function, $U(R, C)$, which the decision-maker (the farmer) attempts to maximize, subject to constraints imposed by the production function and the price equations for capital inputs, labor inputs, and output.

(ii) The returns function is of the form $R_i = A_i F(K_i, L_i)$, where A_i, a production efficiency parameter, varies from farm to farm. The costs function is $C_i = G(K_i, L_i)$. In our application, F and G take specific forms; but never mind, here.

(iii) The hypothesis of maximizing behavior (be it in a profit or in a traditional world), max $U(R, C)$, implies $\partial U/\partial K_i = 0$, $\partial U/\partial L_i = 0$. These partials do not involve A_i. Thus, when U is maximized, K_i and L_i are constants independent of A_i. Similarly, F and G are constants which we may denote by F^* and G^*.

Then it follows that, for max U

(1) $$R_i = A_i F^*.$$

This can take any value between 0 and ∞ as A_i increases from 0 to ∞.

(2) $C_i = G^*$, a positive constant for all A_i.

(iv) We defined traditional behavior as maximization of a specific form of the general utility function, i.e.,

$$\begin{aligned} \max U_i &= \log R - C \\ &= \log (A_i F^*) - G^* \\ &= \log A_i + \text{constant}. \end{aligned}$$

Thus max U can take any value between $-\infty$ and $+\infty$ as A_i varies from 0 to ∞.

(v) Even if max U is negative, it should not be disturbing or implausible to minimize disutility. This seems to us as reasonable as maximizing utility. Moreover, this non-problem disappears completely if we treat the utility function as ordinal or as cardinal but with undefined choice of origin.

(vi) No meaning is to be attached to "plausible" values of R, C, or U since they are, from (iii) and (iv) above, functions of A_i.

(vii) No significance is to be attached to $\partial U/\partial R < \partial U/\partial L$ or, for that matter, to $\partial U/\partial R > \partial U/\partial L$ even if these should occur everywhere. For example, for our second hypothesis, H_2, $U(R,C) = R - aC$, $(a \neq 1)$, if $a > 1$, optimal output is less than profit-maximizing output; while if $a < 1$, optimal output exceeds profit-maximizing output. In this case $\partial U/\partial R = 1$, $\partial U/\partial C = -a$.

(viii) Furthermore, the values of $R = C$ for which $\partial U/\partial C \geqq -\partial U/\partial C$ are totally irrelevant to the existence of the optimum, the relevant maximization conditions being $dU = (\partial U/\partial R)dR + (\partial U \partial C)dC = 0$ and *not* $\partial U/\partial R \geqq -\partial U/\partial C$.

In view of these points we are compelled to reject the "plausibility-of-values" criticism of our traditional model as irrelevant as well as technically unsound.

DETERMINANTS AND DEVELOPMENT IMPLICATIONS OF FOODGRAIN PRICES IN INDIA: COMMENT

John W. Mellor and Ashok Dar in their article in this Journal [1] carried out a detailed empirical study of the relative movements of foodgrain prices and the determinants of those movements and observed that over 80 percent of the variations in foodgrain prices can be explained in terms of the variations in the gap between supply and demand and in the money supply. In this connection, we want to raise two points.

The first point is related to the impact of private stocks on prices. The authors have stated, "Although it is generally assumed that traders do not carry significant quantities of grains from one year to another, there is disagreement about whether farmers do so" [1, p. 968]. It is further stated ". . . that the farmers who produce the bulk of marketed supply have ample financial power to hold stocks, and that such storage may, at least in some years, be highly profitable" [1, p. 968].

It appears that the authors' assumption regarding the behavior of the traders does not seem to be tenable in the Indian situation. The relative impact on prices exerted by the stocks of the private traders is equally, if not more, important than the stocks held by the farmers. The private trade in foodgrains in India includes a multiplicity of operators between the consumer and the producer. The tendency for private enterprise to enter the trade where quick and high profits are realizable has been observed in India in foodgrains. This has merely inflated the cost by multiplying the stages of exchange between producers and consumers. The following two evidences support this view.

(1) The number of workers in food trade increased from 2.4 million in 1951 to 3.4 million in 1961 while its proportion to total workers increased from 2.46 percent to 2.65 percent, in contrast to the relative decline in number of workers in other sectors of trade and commerce [2, pp. 57, 63, 64].

(2) Total resources invested in foodgrain trade also increased in the decade 1951–61. The increased number of traders in foodgrains itself may be taken as an indication of increased resource investment in foodgrain trade. Resource investments from banks and other sources also increased in this period. In one study [3, p. 122] it was maintained that, in spite of actions to restrict advances against foodgrains during periods of increasing speculative foodgrain hoarding, the trend towards a relatively higher level of advances to traders has persisted. Also, sources other than bank advances are more important because the restrictions and checks against speculative hoarding are less effective. The large increase in volume of coop-

erative credit made available in the villages has been used to some extent to finance stocks, particulaarly in the case of paddy in South India [3, p. 122].

All this indicates that the stocks of foodgrains held by private traders are also of considerable significance in determining annual foodgrain prices. In the light of this, the policy implications suggested by Mellor and Dar [1, p. 970], especially the first two, would be more difficult, and their view that "in the longer run, a program of farmer education and collection and dissemination of accurate price and storage information would be helpful" [1, p. 970] may not prove to be so helpful.

A minor point, related to imports of foodgrains, also deserves attention. There cannot be any controversy over the role of the imports in maintaining the price level of foodgrains, but the absence of evidence of an upward trend in imports, as viewed by the authors, should not lead anybody to conclude that the dependence on imports has not risen in India. If we examine carefully the average yearly imports of foodgrains in three plans, it will be clear that over a period of fifteen years the dependence on imports in India, in absolute as well as relative terms, has increased. The estimates of average yearly net imports of foodgrains in the first, second, and third plans are 1.76 million, 3.87 million and 6.45 million tons, respectively, while the corresponding estimates of import as percent of net availability (from domestic production plus imports) are 2.96 percent, 5.57 percent, and 8.38 percent.

A further point may be relevant here. The authors have indicated that the expansion of money is no less a cause for rise in foodgrain prices. In fact, any sectoral price rise, by the same logic, can be traced to the expansion in money supply. In India, if money supply has influenced any set of prices, it is that of industrial raw material prices. The impact of expansion in money supply on foodgrain prices can be traced if one wishes, via the diffusion effect. But here all the prices are involved and foodgrain prices cannot be singled out, for such simple corelation between expansion in money supply and prices can be found with reference to other prices also.

To conclude, in India the whole problem of foodgrain prices rests on two factors: (1) distributive trade and (2) monsoons. If successively two or three monsoons are good, distributive pipelines would burst and foodgrain prices would practically crash. But as yet, India has not had this happy experience.

DETERMINANTS AND DEVELOPMENT IMPLICATIONS OF FOOD GRAIN PRICES IN INDIA: REPLY

It should be clear from the text of our article [3] that we were not dealing directly with seasonal variations in prices but with year-to-year variations in prices. For this reason, we emphasize concern with carryover stock from one crop year to another. Stocks of foodgrains held by private traders within the crop year are substantial and undoubtedly fluctuate considerably from time to time within the year and from year to year. The implication of our statement, however, is that the private trade liquidates its stocks prior to harvest time. Indeed, this is clear from the quotation in the comment by Adhvaryu and Patel. This position is clearly documented in Uma J. Lele's extraordinarily detailed studies of foodgrains marketing in India [1, 4]. As the commentators point out, there has been an expansion of cooperative credit that has undoubtedly facilitated financing of stocks of foodgrains to be carried over from one year to another in the villages. That is, of course, fully consistent with our position. Of course, year-to-year changes in the pattern of seasonality will affect April prices. This we did not deal with and remains as a source of error. Its importance as a source of error is probably minimized in April.

In a country that has large fluctuations in production from year to year due to changes in weather, it is difficult to estimate trends in production. This difficulty will of course be magnified in dealing with the absolutely much smaller residual difference between domestic production and consumption represented by imports. Comparison of five-year averages for the first, second, and third five-year plans is particularly misleading because of the quite different proportion of good weather and bad weather years in these plans. Lele and I discussed this at length in [2]. Statistical analyses of weather data show clearly that the first five-year plan period averaged much better than normal weather, explaining the sharp drop in foodgrains imports in that period, as compared with the preceding periods, and the unjustified optimism concerning progress in the agricultural sector during the First Plan. The Third Plan period was characterized by much worse than average weather, its extraordinarily disastrous last year having a heavy influence on the average. The figures expressing imports as a percentage of production are particularly biased by these problems because in bad weather periods the imports will be larger in absolute terms and the base of total supply will tend to be somewhat smaller.

One can expect expansion in the money supply to affect all prices. Our point, however, is that the impact on foodgrains prices has been somewhat different from the effect on other prices. We point out at some length that care must be used in interpreting this figure.

The problem of foodgrain prices in India is much more complex than Adhvaryu and Patel make out in their last paragraph. My colleague and I deal with this at much greater length in [3]. Adhvaryu and Patel are of course correct in pointing out the special impact of a succession of good weather years. Contrary to their statement, India has indeed had such experiences, which we analyze statistically in our paper.

EFFECTS OF NONPRICE VARIABLES UPON PARTICIPATION IN WATER-ORIENTED OUTDOOR RECREATION: COMMENT

There are basically three things wrong with the Gillespie and Brewer piece [2]: (1) the amount of explained variance reported, (2) the dependent variable, and (3) the handling of the intercorrelations and curvilinearity in the independent variables.

Taking the problems in reverse order, there are two acceptable ways of handling intercorrelations and curvilinearity. One is through the use of dummy variables, in which the intercorrelated variables are grouped together and the coefficients of the various dummies compared. If continuity must be maintained for some reason, it is also possible to include both a variable and a square, by using the square of the difference between the value of the variable as observed for a given individual and the mean of the variable for the sample as a whole. This squared term will not be correlated with the initial value of the variable.

The effect of using "number of visits" as a dependent variable is to give a person who made ten visits ten times the weight assigned to a person who visited only once. If the former had a higher income than the latter, this gives a great deal of weight to higher income people. If what you want to do is to predict the number of visits by some group or sub-group in the population, this is an appropriate statistic. If, instead, you want to find out whether or not lack of income prevents people from participating in outdoor recreation, this is not an appropriate dependent variable.

As to the R,^{2} I think it is grossly in error Analyses of household survey data, the type Gillespie and Brewer apparently had, do not explain more than 15–20 percent of the variance using *their* kind of dependent variable [1, 3]. With a "grouped" or dummy dependent variable like that mentioned above, the R^2 can be expected to be as high as 30 percent [4, p. 27].

An alternative to their analysis of

data is to change both the dependent and independent variables. I have done this for a sample of adults in Wisconsin. The regression is shown in Table 1. The dependent variable used a grouped activity index in which people were classified by frequency of participation, i.e., 0 = never; 1 = 1–4 times; or 2 = 5 or more times. (This kind of dummy dependent variable was also used by Mueller [4] and more extensively by Lansing [3].) These scores were summed for each of nine activities similar to those measured by Gillespie and Brewer.

The use of dummy independent variables makes a number of things possible. For example, income elasticities can be estimated that differ among education groups or over different ranges of income. Thus, it appears from the statistics in Table 1 that a single income elasticity for general participation in outdoor recreation is probably inappropriate. The elasticities will differ among education groups; elasticity also appears to differ over the income range. The difference between our approaches to the independent variables is that I am asking for the best fit for a subgroup of the population; they are asking for the best fit for the entire population. To isolate the effect of income and education, they give up two degrees of freedom by adding two parameters (education squared and "the product of income and age"), which invalidates their *t*-ratios and makes the effect of their coefficients more difficult to decipher. To do the same thing, I have added nine parameters and come up with a set of variables whose effect and significance is easy to observe.

Joe B. Stevens, in his comment [5, p. 193], alluded to a lack of significance of several of the variables. It is not possible to put both of the intercorrelated variables in the same regression without changing the regression coefficients and invalidating the *t*-ratios. For example, in an analysis using Gillespie and Brewer's model, but *my* data, the correlation between age and age squared is .985; between education and education squared, .979; and between income and "the product of income and age," .887. There seems no reason to suppose that these will differ very much with Gillespie and Brewer's data. In the regression using only two variables, income and age explained 10 percent of the variance. The coefficient for age was −.6547 with a *t*-ratio of −7.1203, highly significant. When the next regression was computed with income, age, and age squared, the coefficient for age was −.7064 but with a *t*-ratio of −1.31, while for age squared the coefficient was .00353 with a *t*-ratio of .097. Thus, with both age and its square in the regression, the *t*-ratios of both appear to be insignificant; yet the effect of age is, of course, significant.

It is hard to believe that the *determinants* of participation in outdoor recreation have a more consistent effect among people living in St. Louis than among those in Wisconsin and/or the nation. I am quite willing to believe that, on the average, people in Wisconsin participate more, just because of the ease of getting to the supply of outdoor recreation. This in fact, appears to be the case: the average in Wisconsin was 35.5 times, while in St. Louis it was 27.3. When my data was regressed using the dummy *independent* variables suggested above, but a linear *dependent* variable like Gillespie and Brewer's, the explained variance was about 15 percent, depending only slightly on the way the independent variables are treated. Running *my* data using *their* complete model again shows a low explained variance: $R^2 = .14$ (see Table 2). However, my data is for an entire state, in which only 30 percent of the population lives in a metropolitan area. If the people in St. Louis do behave more systematically than people throughout the nation generally, this is a most important finding and one that should be tested in other metropolitan regions. In fact, it has been tested in Detroit; but the findings for Detroit suggest that: (a) the determinants are similar to what I found in Wisconsin and what was found nationally, and (b) that we may expect a *lower* rather

Table 2. Estimates of parameters

Farmers	−18.87	−1.35	8	Unemployed	−4.67	−1.39	1

Constant term = 58.27
$R^2 = .136$
$N = 758$

Constant term = 53.5
$R^2 = .62$
$N = 1000$

than higher R^2 in metropolitan areas [3, p. 176–9].

In conclusion, while I think it is important to isolate the determinants of participation in outdoor recreation, this must be done so that the results reflect the underlying relationships. The Gillespie and Brewer model is inappropriate, if for no other reason than that it can mislead someone as sophisticated as Joe B. Stevens into thinking that the effect of age is *insignificantly* negatively related to participation rates.

FEEDBACK FOR STUDENTS ON CLASS PERFORMANCE

Students have the right to know where they stand in their various classes—before the end of the term! A newly developed program at Purdue University called the Student Grade Report (SGR) does just that plus a lot more. This computerized system provides the instructor with an analysis of individual and class performance on which he can evaluate progress and eventually assign grades at the end of the term. The system results in more accuracy with considerably less effort than conventional grade books.

Students are the big winners. Each student receives a "print out" several times during the term that shows the official record of his scores, along with class averages for each item. The total weighted average is clearly calculated, and the student's class rank is shown. Also included is an anonymous list of the averages of all other students to show how much a student must improve to get a certain rank or grade.

"The SGR was a great motivating device for me!" reported one student. Another indicated that ". . . I really like knowing exactly where I stand." These comments are typical of the responses from students who were given Student Grade Reports by their instructors periodically throughout the semester.

Some 275 students in five different classes responded to a recent questionnaire about SGR. Results show that 88 percent felt that the SGR's were of high or very high value to them. More than 75 percent felt the system was "more accurate" than conventional grading systems, because they were sure of the scores recorded for them and could see the calculation of their averages. More than three-fourths of the students felt that SGR helped motivate them, while only 6 percent indicated any discouragement as a result of the reports. Students like to know where they stand. They like SGR.

Instructors like the Student Grade Reports, too. SGR provides the instructor with the same information given his students, but conveniently summarized for quick evaluation of group and individual performance. For example, the instructor will find raw scores converted to standard scores with a mean of 50 and a standard deviation of 10 to show relative performance. Student performance is summarized alphabetically as well as by seat number for easy reference. Of course, conventional raw scores are also shown.

The system is unusually flexible. Instructors are free to use any predetermined wighting system they wish. There can be up to five different types of scores (quizzes, term papers, exams, etc.), with up to fifteen of each. As many as several hundred students can be processed for a given class. SGR will accomodate excused absences; it will also drop the one or two lowest performances from each student's total score, if the instructor so desires. Additionally, it gives the instructor an analysis of excused absences, zeros, and missing work.

The SGR is simple to operate. After a class is "set up," only a few cards need to be punched prior to a summary. Clerical or student help seem to have little trouble with processing. Expenses for the system are minimal, with computer cost at five to ten cents per summary. The program is written in Fortran IV and is adaptable with little alteration to computers found on most campuses today.

During the spring semester, Purdue had about 1200 students in the School of Agriculture receiving SGR periodically. The system has been growing in popularity with the students and instructors. The advantages of quick feedback, motivation from "knowing where you stand," spotting troubled students early, convenient class evaluation, and accurate, fast analysis of performance in the hectic moments before grades are due are all reasons for this popularity.

And our students have a right to know!

A NEW LOOK AT DEMAND ANALYSIS FOR BEEF: COMMENT

Uvacek, in a recent article in this Journal [3], hypothesized and attempted to prove that the cattle cycle was a demand shifter for beef. He concluded that annual adjustments in the demand for beef were due to changes in per capita income, while abrupt shifts in the demand for beef were due to production cycle alterations.

The validity of the theoretical argument presented by Uvacek is questionable. He assumes one demand curve during the build-up years of beef production cycle and a less elastic demand curve during the liquidation years of the cycle. Contemporary economic theory [2] usually theorizes that income, population, tastes and preferences, and prices of substitutes and complements are the demand shifters.

Agreeing with Uvacek that the traditional demand shifter income has caused the annual shifts in the demand for beef, it is possible to explain the less elastic demand during the liquidation years of the cattle cycle without theorizing that the cycle itself is a demand shifter. Uvacek states that the cattle cycle is positively correlated with slaughter levels [3, p. 1502]. However, the peaks and troughs of the production and slaughtering cycles do not coincide (Figure 1).

For the time period used by Uvacek, the slaughter cycle hits its bottom in one instance two years later and in another instance one year later than does the production cycle and hits its peak one year behind the peak of the production cycle. Thus, while the production cycle would show a decreased amount of beef available during the first year of liquidation in the beef production cycle, actually the supply of beef is increasing as shown by the slaughter cycle.

The larger supply during the beginning of the liquidation phase of the production cycle could shift the supply curve to the right. Assuming such a shift in the supply curve and a linear demand curve, the intersection with the demand curve would be further to the right and in a less elastic area of the demand curve. Thus, the less elastic or inelastic demand during the liquidation phase of the production cycle is not a shift in the demand

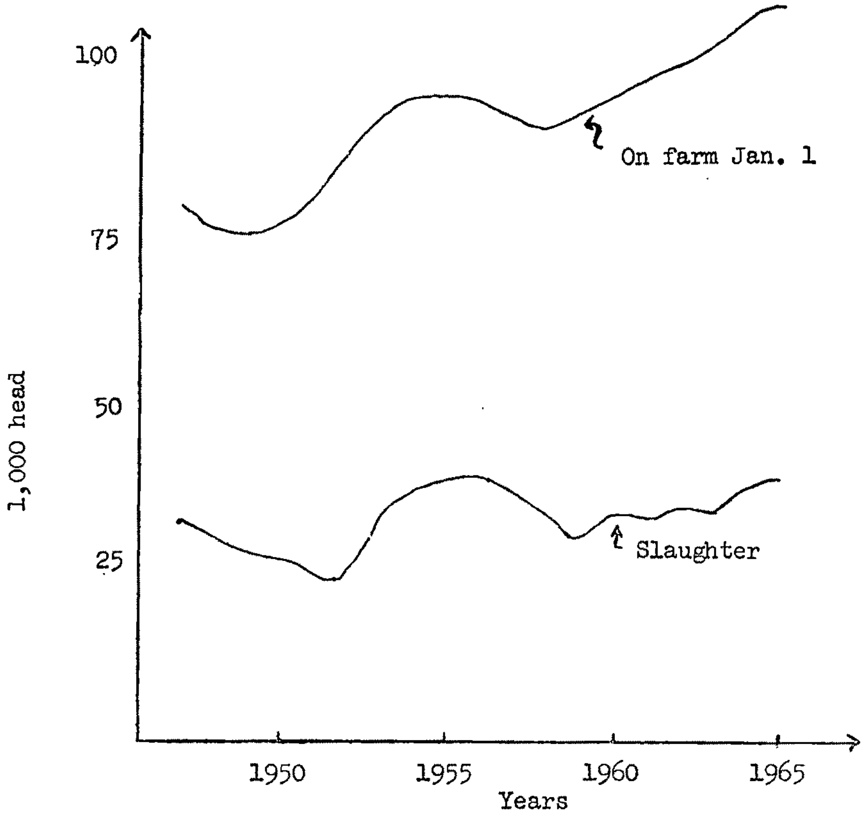

Figure 1. **Total number of cattle and calves on farm January 1 and slaughtered in the United States, 1947–1964**

curve but a change in the quantity demanded.

In addition to the questionable status of the theoretical argument presented by Uvacek, the methodology he employed to test his hypothesis lacks rigor. First, the coding system used for the dummy variable representing the production cycle in no way depicts the cycle (1 for 1947–48, 2 for 1949–1954, 3 for 1955–1957, 4 for 1959–1964, and 5 for 1965–1966). A 0,1 coding system, 0 for build-up years and 1 for liquidation years, would depict the trends of the cycle that Uvacek's coding system failed to do. Second, there does not exist any type of economic interpretation for the coefficient associated with the coded production cycle variable. It is difficult to assign economic significance to a sequence of discontinuous but equal downward shifts in the demand curve each time we move into a new phase of the cattle cycle, regardless of whether the new phase is one of expansion or contraction. Even more damaging is the lack of relationship between Uvacek's stated hypothesis and the statistical model postulated. Third, Uvacek previously accounted for the production cycle in his regression model with variable X_1 (beef production per person) and therefore lacked any economic or statistical reason for introducing the variable. In addition, there is a high degree of multicollinearity among Uvacek's independent variables.

The proper methodology for testing Uvacek's hypothesis of a different slope and intercept would be that outlined by Johnston [1, pp. 221–228].

Uvacek's equation in general terms would then be:

$$(1)\ Y = \alpha_1 + \alpha_2 X_9 + \beta_1 X_1 + \beta_2 X_6 + \beta_3 Z$$

where

$$(2)\ Z = X_9 X_1$$

and

$$X_9 = \begin{cases} 0 \text{ in each build-up year} \\ 1 \text{ in each liquidation year} \end{cases}$$

X_1 denotes the beef production per capita, as shown by Uvacek in his final model [3, p. 1505]; X_6 is disposable per capita income; X_9 is a 0,1 dummy variable depicting the phases of the slaughter cycle; and Y is the wholesale choice beef carcass price.

With equation (1), we have assumed a different intercept and slope for the build-up and liquidation years of the beef slaughter cycle, and therefore tests of significance on the proper coefficients would test for each, α_2 for the intercept and β_3 for the slope.

A NEW LOOK AT DEMAND ANALYSIS FOR BEEF: REPLY

The criticism levelled at my recent article [3] by Folwell emphasizes two obvious factors: (1) All details of an analysis cannot be contained in a six-page contributed paper; and (2) it certainly pays to attend the sessions when such papers are presented. Many of the questions raised by Folwell were either offered in the actual presentation at the meetings or covered in the discussion period that followed. For the benefit of those who were unable to participate, let me specifically reply to the objections raised. Most references are to those publications previously cited in the reference list of the original article.

Fortunately, there are many in the profession who are constantly seeking answers beyond what contemporary economic theory can provide. Let us hope that contentment never completely settles in, and that we continue to experiment with new ideas and techniques.

Perhaps the basic ideas of my proposed demand shift concept were not fully understood. First, it is already recognized by many contemporary economists (such as Waugh and Working) that abrupt shifts in the demand for beef do actually exist. The real problem remaining is to identify the timing of these shifts. Secondly, per capita income changes no longer provide a full explanation for changes in the demand for meat, as emphasized by Working and Meinken. Elaborate details on other factors affecting the demand for meat can be found in such analysis as that provided by Holmes [2]. Thirdly, the basis for suggesting separate demand curves for each phase of the cattle cycle rests upon the concept that irreversible demand curves exist for beef, resulting in completely different curves during periods of increasing supplies versus supply reduction periods.

Contrary to Folwell's analysis, even though the peaks and troughs do not always coincide, the cattle numbers cycle, according to most statistical criteria, is highly related to cattle slaughter levels. Such graphic cohesiveness is hardly regarded as a requirement for a significant correlation. May I suggest that, when a comparison of the data for the years 1948 to 1967 is viewed on a semi-logarithmic scale and the correlation coefficient of .9447 is examined, the relationship becomes quite apparent. This relationship between numbers and slaughter, even though not perfect, is highly important since it is the cyclical changes in numbers that provide a "time element" to these demand shifts.

Any analysis of these two series, however, must recognize the fact that the cattle numbers estimate is a figure representing inventories as of the first of each year, while the slaughter level is the total kill during that calendar year. Complete comparability, therefore, may not be possible. The first year or so of the buildup of the cattle numbers cycle usually involves a holdback of cows for breeding, resulting in somewhat reduced slaughter and, therefore, an opposite reaction to the positive correlation. Similarly, the first year of the liquidation phase creates some problems since cow culling is severe and more are sold, temporarily forcing slaughter to slightly higher levels. In each case, however, the composition of total slaughter is changed. It is primarily the cow slaughter that decreases or increases and reacts opposite to the established cyclical relationship. The type of cattle killed during these critical years of the cattle cycle becomes of paramount importance to any analysis of beef demand.

Changes in yearly supplies of beef, provided by variations in the cycle, have been adequately explained by the rancher's reactions to price levels. Thus, they do represent shifts in supply curves. It has been pointed out that when both supply and demand curves shift, the analysis of consumption and supply data traces out what may look like a structural demand or supply curve, but with an extreme slope [1, pp. 53–56].

On the other hand, within a year, the quantity of beef is predetermined by the number of animals on farms and ranches as of the first of the year. Working emphasized that the measurement, through demand analysis, with such an almost verticle supply curve, yields an average demand curve. Even though economics and statistical theory lessen the significance of such a regression line compiled from such data, its usefulness in forecasting has been frequently proven.

As indicated in the first part of my

paper, the entire concept was offered to stimulate some new attempts at dealing with price prediction and was not meant to present an econometric analysis or explanation of the pricing system. This chore was not ignored, however, but rather relegated to a less significant contribution in my dissertation.

The coding system used to represent different phases of the cattle cycle was statistically tested for several months and through dozens of regression analyses before the final codes were accepted. The obvious 0,1 coding system suggested by Folwell was one of the first attempted but was discarded because it did not prove to be statistically significant and it assumed the economic interpretation that the buildup years of the cattle cycle could be consolidated and, therefore, that identical slopes exist during this same phase of each succeeding cycle. A similar consolidation of the liquidation years is inherent in the proposed code. However, graphic analysis indicated that the beef demand curves did not appear to have the same slopes and that, in fact, the demand curve during succeeding buildup phases was actually becoming more elastic.

The economic significance of the finally accepted coding system seems quite apparent. It implies that each phase of the cattle cycle must be studied separately, since a new demand curve may exist during each period. A cycle-time dummy variable was therefore introduced. It contains much more economic substantiation than an arbitrary division of the years under study into two or more equal periods, as frequently done in previous beef demand analyses. These researchers have implicitly assumed a different demand curve for each group of years.

The beef production per person variable is offered in my equation as a demand indicator, even though it is usually stated as a per capita consumption figure. The coded value also is derived from a production cycle and is offered as a demand indicator. Since Folwell had difficulty in grasping the economic significance of this coded demand indicator, it would seem that multicollinearity would be equally difficult to identify among the independent variables. The presence of serial correlation, however, was thoroughly examined and none of the tests was conclusive.

Interesting enough, the suggested procedure outline in Johnston was not attempted. It's economic interpretation, however, would have to mean that the demand curves during the buildup phases of the cycle are related, as are the curves during the liquidation periods. By utilizing the code twice, for example, the same slope and intercept is assumed for the 1949–54 and the 1958–64 data. My analysis emphasized, however, that separate demand curve slopes and intercepts exist for each phase of the cattle cycle and that the relationship between phases of succeeding cycles is only casual.

Demand analysis of beef, in the past, has been choked with the traditions of our profession, with the result that it was inadequate as a forecasting tool. Possibly this first attempt to add a dimension to the abrupt shifts in the demand curves for beef, if only a clumsy start, can stimulate a whole new era of enlightenment.

THE UNSEEN—AND UNFEELING—HAND

Considering the alternative of having done nothing, I submit that we are fortunate to have had some of the inconsistent schemes and programs that we have in agriculture, such as:

1. Surpluses, with the experiment stations continuing to pour out cost-cutting and output-increasing innovations.
2. Surpluses, with the politicians getting more dams and irrigation projects set up so that there will always be more and more food and fiber production.
3. Acreage taken out of production to keep farmers alive in spite of 1 and 2 above.
4. Federal payments to planters not to plant, but not to their workers not to work.

We are fortunate because:

1. The world needs all the productive capacity and technology that have been developed for plentiful food to give energy to the world's finest resource, the people.
2. Things might have been worse in the United States without the programs; not considering the assurance of future food supplies here and abroad.
3. How do you have enough without having a surplus? This question was called to my attention by Professor Kohlmeyer. I think it is one that might be asked by everyone from, for example, Oren Lee Staley to the compilers of the 1967 Random House Unabridged Dictionary. Dare we define part of the U.S. agricultural produce as surplus when people hunger?
4. If farmers are to compete with corporate research and remain the managers of agriculture, they will need their publicly-owned research complex.

A grand foresight might have eased adjustments along the way. As Dean Acker of our institution has said, the tragic migrations of millions from agriculture to urban ghettos cried out for some sort of national policy on population distribution.[1]

---

[1] Perhaps a United States Department of Human Ecology, cutting across rural and urban lines is our need. An effective national policy would face the question, not only of whether to encourage or discourage migration of "surplus" people, but also how and whether to help retain in agriculture or train or employ those who do not migrate as well as those who do. It should consider the impact and use of a guaranteed annual income to hold back the flood of migrants and to offset partially the need for cheap food. It could even consider influencing the rate of adoption of technology. Down the

We didn't hear in time; but if we survive that oversight, we are prepared for the more distant future. America's unrelenting pursual of agricultural research and development, although it filled our ghettos and caused untold misery, is the world's insurance against future hunger.

RAYMOND O. GAARDER
South Dakota State University

road, it would hope to anticipate potential surpluses and deficits of people and be able to prevent their development.

REGIONAL RESEARCH—FURTHER ANALYSES AND REFLECTIONS[*]

Regional research provided for by legislative act has been with us since 1946. In this 23-year span, there has been little unanimity of agreement as to what procedures would give a satisfactory and productive program.

One of the most comprehensive articles to be published on regional research recently appeared in this Journal [1]. It reviewed the apparent weaknesses and many dissatisfactions with the program and offered some suggestions for possible improvement. The authors—Harris and Hildreth—made objective and comprehensive analyses that provide a basis for comments and dialogue among those who are closely associated with the program.

I shall first summarize the problems listed by the authors and analyze the suggestions made by them and thereafter present what I consider to be the key elements for achieving improvement.

Characteristics and Problems of Regional Research

The following characteristics of regional research were cited as obstacles to the development of effective cooperative regional research: (1) a large proportion of umbrella-type projects, which results in grouping of unrelated state activities; (2) the predominance of state and local viewpoints of administrators and researchers; (3) committees that are too large for effective cooperation; (4) insufficient time allowed for the planning process; (5) absence of centralized leadership and staff for implementation, coordination and report writing; and (6) the low regard in which regional research is held by the more able researchers. There can be little disagreement with this list of problems. This characterization of regional research and the problems of its administration are real and evident to anyone involved in the program.

Other problems noted were: (1) that regional research requires excessive paper work in getting approval and in preparing the annual progress reports; (2) that regional research is not undertaken until the problem is in full bloom; and (3) that the results of technical research are not adapted and interpreted to non-technicians. These problems relate to all research and should not be enumerated as particularly characterizing regional research.

---

[*] The opinions expressed are those of the author and may not represent those of the Cooperative State Research Service of the U.S. Department of Agriculture.

An Analysis of Their Suggestions, and Alternatives

Harris and Hildreth say that their suggestions for improvement may have been considered from time to time and that the complexity of the problems associated with the committee system does not permit a single prescription for improvement. I shall discuss each of their suggestions.

1. It was suggested that CSRS prepare a periodic analytical report on regional research that would give the status of the program and the underlying philosophy, objectives, and procedures, and that these be suitable to the needs of individual researchers on all regional research projects. This might be a useful exercise, but I believe such reports would be too generalized to help the specialized researcher. Opinions on what is productive regional research are now so varied that it would be difficult to lift up examples for illustration.

2. It was suggested that regional research funds be used to expedite development of intellectual resources through providing opportunity for station and USDA personnel to meet and discuss research problems of mutual interest. This is now possible, if it relates to regional research planning, as CSRS has recently developed procedures that permit use of regional research funds for payment of travel costs to such meetings, without the prerequisite of a specific project outline for that research.

3. Another suggestion was for experimentation with a broad program of research for a regional committiee rather than a project on a narrowly defined problem. In my opinion, adoption of this idea would do little more than divide the regional research funds among disciplines without knowing what the researchers propose to do.

We have *de facto* program committees now in the many umbrella-type regional projects under way, but this was not the intended purpose of the regional program. A better way to exchange ideas, develop theories and concepts, and stimulate intellectual development would be to encourage establishment of seminar-type research committees, similar to the Farm Foundation committees and other committees in the North Central Region. Such groups do not pretend to work on specific regional projects, but individual members initiate State projects on their own. Occasionally topics are spun off for development into cooperative regional research projects.

4. The suggested employment of a coordinator as an executive for the regional committee is already an approved practice and several committees have had and now have such a person. A coordinator can be effective if the problem and research plan lend themselves to central direction and operation and give him opportunity for intellectual leadership. I would conclude that a coordinator is fine under certain circumstances, but as a general rule this idea will not lift regional research to higher accomplishment.

5. Use of a research center to carry on the work for a regional project has been a practice since the early years of regional research. It is a particularly good idea for new plant introduction, study of poultry and animal diseases, and similar projects requiring a large investment in physical resources. The practice should not be overextended; such centers have a way of becoming more or less independent institutions and would drain away funds intended for the States.

6. That fewer members would make a stronger and more effective research committee has often been expressed and is generally agreed to be a desirable policy. While small committees might produce more regional projects, it seems certain that each could be a real cooperative effort and thus more effective. The idea of having fewer States involved in a regional project usually gets stymied in the project approval process, because an original proposal with few intended cooperators tends to be interpreted as a subject of little interest.

In addition to the above suggestions, Harris and Hildreth presented two general alternatives: (1) that regional research be supported only from the regional research fund, or (2) that the regional research system be dismantled.

With only one source of funds for regional research, the directors and other concerned administrators might be more likely to look at problems from a regional viewpoint in the project review and appraisal process. At present, regional, regular Hatch, and non-Federal funds are all used to finance a single project, thus tending to blend the programs as well as the funds.

Dismantling of the system entirely would necessitate changing the law to eliminate the regional research feature of the Hatch Act. Nothing so drastic is needed, for the law states: "Not more than 25 percentum shall be allotted to the States for cooperative research in which two or more State agricultural experiment stations are cooperating to solve problems that concern the agriculture of more than one State." A literal interpretation of this provision means that it intended administrative discretion to be used in determining what funds were needed for regional research, up to a limit of 25 percent (of the amount that represents the increases since 1946). The legislation seems thus to have provided for a system whereby the regional research would be developed according to needs, with allowance for discretion as to the amount of funds assigned thereto, up to the 25 percent limit. Apparently, it was not intended that a given fixed percentage be assigned to regional research, regardless of needs.

Two Basic Elements Need Consideration

The article by Harris and Hildreth is well done and comprehensive. However, I contend that it did not specifically bring to light the crucial and primary obstacles, nor did the recommendations zero in on the key elements basic to a satisfactory program. In my opinion, two basic elements are essential for successful regional research: (1) an adequate planning period, so that researchers accustomed to the individualistic approach will have adequate time to develop concepts, an understanding of the problem, agreement on what is relevant, and agreement on scope and methodology; and (2) a regional research program that is distinctive and separate from the total agricultural experiment station research program, rather than a blend and indistinguishable part of it. These points are mentioned by Harris and Hildreth, but apparently are considered to be merely on a par with other obstacles and alternatives. My contention is that the entire structure of regional research is dependent upon the extent to which these two elements are recognized and dealt with. All other elements or problems are secondary or merely symptoms.

Adequate time for planning

The research specialists selected for a regional research committee participate voluntarily, and no one has authority over anyone else. Furthermore, each committee member is a capable and independent thinker and sees a problem in the light of his own experience. In addition, each committee member is already busy and concerned with making his own significant contribution in his own area of research on his own campus, where he is responsible to his own administrators for recognition and advancement. Because of this distinctive situation, it is essential that there be considerable lead time before a specific project outline is prepared.

For the development of a significant cooperative regional research project, two or three seminars are needed to enable committee members to agree on the nature of the problem, to develop concepts and theories, and to agree on the procedures and research approach. This will take time and should be approached from the general to the specific. Seminars must be purposeful and held with the idea that a cooperative regional effort is to be undertaken. It is assumed that a wide-ranging exploration of a general field is not the responsibility of this type of planning group. The general problem area has already been identified and the seminars should deal specifically with the named problem area as to the present state of knowledge and further research needs. It is possible that a group might decide that sufficient knowledge already exists or that other research areas have higher priority for use of time and other resources. If the committee concludes that further research is needed and has high priority, it should move to the next phase of project planning. Before the research can get underway, the individual committee members must complete other unfinished projects, recruit graduate students, and make other administrative arrangements for initiating the new research.

The administrative advisor and the CSRS representative should inform the planning group whether they believe the proposal being developed would be acceptable as a cooperative regional project. These two in turn need to have standard guides as to what constitutes cooperative research effort on a problem that cannot be handled satisfactorily in a single state. Uniform and consistent standards and adequate time for planning are needed to prevent regional projects from merely being a collection of uncoordinated state projects.

Regional research—a separate program

The second point for improvement of procedures and policies for regional research involves handling its financing in such a way as to facilitate its development as a distinct program—one that is different from other segments of the agricultural research program. The difference should be due to the nature of the problem in that it is of concern to more than one State and requires coordinated and cooperative effort. At present there is a tendency to distribute the regional funds to all disciplines and research areas without prior study of what problems or phases of problems need cooperative effort.

One way of building a regional research program would be to decide first what areas to include and then to finance these with regional funds only.

This would have the effect of reducing the number of regional projects. Blending of all sources of funds possibly increases administrative flexibility, but it weakens the opportunities of adhering to agreed upon standards of differentiation. If high and uniform standards are followed in accepting areas of research for use of regional research funds, it is likely that the program could be substantially reduced and that less than the permissible amount of funds would be needed. This would permit distribution of the excess on the basis of the regular Hatch formula.

Researchers must do their part in making effective use of the regional funds. They must make specific commitments to carry out certain responsibilities and set forth the resource needs. Research workers will be able to do this if sufficient time is provided for planning among themselves and for communication with their administrators—department heads and station directors. In addition, standards as to what is acceptable as a regional effort and what constitutes cooperative effort must be uniform for all committees and all disciplines. If this is not done, the entire system may regress to competition for leniency, making the main concern that of getting the project approved so that one's fellow workers will be certain to "get their share of the funds."

"SUBSISTENCE AGRICULTURE" AND TECHNOLOGICAL CHANGE: FURTHER DISSCUSSION OF THE THEORETICAL PROBLEM

A recent and most useful addition to the literature on "subsistence agriculture" has been provided by Dr. Marvin Miracle in this Journal [1]. The Miracle article has been the catalyst in the decision to write this note, ideas for which have been "brewing" for some time. Few of the ideas, if any, are new to the literature; but they are here brought to bear in a relatively new form, I think, on the analytical and theoretical formulation of the concept of subsistence.

The economist interested in the rural economic development of low output nations must center his attention on the basic issue of production. Agricultural development is the movement of a farmer or a herder, or a community, or a society, from a lower to a higher (and usually more secure) average level of productivity. Certainly, in the numerous projects in which I have been involved in parts of South America, the Near East, and Africa, the practical core issue is indisputably the movement toward a more efficient production technology. A great number of other things are usually necessary to achieve an improved technology: roads, better institutions for credit, marketing, farmer training, etc. But the underlying goal is an enhanced and/or more varied output. As I have said elsewhere [2, p. 9], the core of development "is *not* the transfer from no money to money, no exchange to exchange, no market to market, though these institutional mechanics may attend the process."

An improved production system is the central development issue, regardless of the sector being examined. In developed or underdeveloped countries, in every line of economic activity, there is a spectrum with the least efficient at one end (the adder of columns of figures by hand; the back-carrier of goods over bush trails; the hand cultivator) and the relatively more efficient at the other (the calculating machine worker; the driver of a five-ton lorry carrying goods to market over a paved road; the tractor cultivator). The most ignorant and unskilled are at one end of the scale, using the least efficient technology and systems; the more skilled are at the other, interested in and capable of using more advanced technology [see 3, 4].

The normal fabric of "Western" economic theorizing regarding development is geared to the use of particular aspects of the institutional mechanics referred to above. Our development models divide economies and agricultural sectors into several pieces in terms of one or a number of these institutional mechanics (dual economy development theory, for example). The no money/money dichotomy, the no investment/investment dichotomy, the rural/urban dichotomy, the no market/market dichotomy, the nonindustrial/industrial dichotomy: all these ways of looking at and attempting to posit the development issue are non-exclusive and non-scientific. Most importantly, they do not concentrate on the real source and nature of development. The heart of that matter is technological change.

The attempt to work with the concept of subsistence has been partly caught up, I think, in this general misdirection of our theorizing; we are trying gamely, as a profession interested in our theory, to work our way out of the theoretical box we find ourselves in. We *know*, from our collective practical experience, that agricultural change comes with improved systems of production. We *know*, as a matter of record and experience, everywhere, that this essential improved technology requires more motivated, skilled, and capable farmers. Yet we are theoretically nervous because we also know that the theoretical tools provided by our discipline are inadequate to handle this basic knowledge, these fundamental *facts* of development in the high *or* low output agricultural communities.

As Miracle indicates (also Wharton, Mellor, Johnston, and others), there are several general meanings of the word subsistence, including particularly the level of consumption of the farming or herding family, the proportion of the output that is marketed, and the percent of total family or community income that is money. I would submit that to use the term in these senses is utterly misleading, at least for policy and for theory. The development policy implication of these interpretations into which our theorizing has led us is that of concentrating on "monetizing" these rural economies by increasing the share marketed.

We are thereby side-stepping the key point on which we should be concentrating—technological change—and simultaneously dealing only with the edges and some of the characteristics of change, not the root causes that give us sustained rural development over the medium and longer runs. Adam Smith tells us to extend the market to obtain specialization of production and increased productivity. That is fine, but we have to have something to market, and that comes from a constantly improving production system.

Certainly, wherever I have been involved with practical rural development projects or conducting research, I have encountered examples of situations in which the percentage marketed is going up, while productivity and the standard of living are simultaneously going down. Conversely, I continually examine cases where the standard of real per capita output and consumption is rising, although the percentage of production marketed is declining.

I have studied and worked with examples of the former in central Sudan, in the Khuzestan (Iran), in numerous Indian communities of Colombia north of Bogota, in Kenya and Malawi, in Tanzania and Uganda, in (what is now) Biafra, and in the Ivory Coast. The usual pattern reflects a falling total output per capita due to declining soil fertility, smaller farm size, erosion, etc. The non-food cash needs, as well as the cash needs for food purchase in some cases, require that a roughly constant or even rising absolute volume of output be sold; this is a progressively larger *share* of a falling total output, and per capita food supplies fall, often rather quickly. The livestock societies in the Near East and Africa experience a similar process. I cannot speak for everywhere, not having been everywhere, but in those places where I have been involved, on the ground, this is a rather common experience.

Conversely, there are numerous examples of improvements in the system of husbandry and technology of food crop production leading to striking changes in the volume and diversity of food crops available. More might be sold, but sometimes a greater percentage is consumed. Often the change in food crop production technology is greater than the change in crops grown for cash sale, especially where this occurs after the cash cropping systems are well established. Consequently, at a higher overall level of farm output and living standards, one has "regressed" more toward a subsistence level in which the *proportion* of output being sold is lower! This situation is particularly common where appropriate fertilizers and seed strains are being used effectively to improve food crop production systems. This, too, is a very general development experience, and the opposite of one of the more popular meanings of subsistence.

It is legitimate to ask if we even need the concept of subsistence at all. We do need it, definitely, if we accept the idea that monetization and marketing are the "guts" of the development process. If they are *not*, the usefulness of the concept is severely emasculated for theoretical purposes; we are on side roads, not the highway. This observer's total experience says that they are *not* the "guts", but that technology and its changes as they affect the production process are indeed the real stuff of development. This is not to deny that improved marketing and related facilities, land reform sometimes, etc., are not critically important pieces of an overall package of inducements to change; they usually are—they permit, like roads. But permit what? More and improved production, which is what we are after.

If we accept this as a reasonable proposition, then we must, of course, be ready to cope with the consequences of that acceptance on our entire theoretical structure. I certainly have not thought it all out, though I have made some hesitant beginnings. If it is true that we really should be formulating development theories geared to a technological spectrum, as distinct from these others, what happens to all of our macro and sector development models that also are based on these related but tangential factors (instead of technological variables of some kind)?

I am not claiming to be correct in all this. Far from it: I am groping in the intellectual dark. But I do know what I see. And I know what my economic theorizing tells me. And I cannot make the two live together.

SOME THOUGHTS ON BARGAINING

Bargaining is being mentioned with increasing fervor as a possible means of gaining higher prices and, hopefully, higher incomes for agriculture. Before bargaining can effectively raise prices, the supply of the product in question must be controlled. Although rigid supply control is not impossible, it would be a difficult accomplishment for commodities produced over wide geographical areas—the situation that exists for most of our major agricultural commodities. Whether a majority of farmers can, or will, band together in an effective bargaining group remains to be seen.

Asuming that farmers will stick together and effectively control the supply of a product marketed, how will the problem of product substitutes be handled? It is undeniable that when we raise prices for agricultural products, by whatever means, we openly invite competition from product substitutes. In many instances, while pursuing higher farm prices, we have already lost large segments of markets that formerly belonged totally to agricultural products. It is true that people must continue to eat, but there is no guarantee that the foods will continue to be demanded in their present form (e.g., cow's milk, beef steak, etc.), that they will be domestically produced (products made from foreign soybeans might taste just as good), or that they will even be agricultural products at all (e.g., artificial sweeteners).

Many propose that agricultural producers be given protection by outlawing the sale of some substitutes or by instituting such rigid marketing or labeling requirements as to make the cost of substitutes prohibitive. Others would readily deal with foreign competition that might threaten higher U.S. domestic food prices by instituting rigid import restrictions. Such restrictions may achieve the desired objective of particular groups of producers in the short run. However, the opposite side of the import restrictions coin is a loss of export sales—a high price to pay when agricultural producers are hopefully looking for foreign markets for additional outlets for larger portions of major agricultural crops.

Farmers alone cannot expect to secure legislation needed to restrict competition from substitute food and fiber products even in the unlikely event that all the many diverse types of farmers act in concert. Could they depend on help from urban consumers to pass legislation to make bargaining work? Successful bargaining would clearly mean higher retail prices. The nationwide demonstrations of housewives in response to hikes in retail food prices may provide a clue to the answer.

In 1968 taxpayers' generosity increased net farm income by $3.1 billion, or 28 percent, through government payments to farmers alone. It has been estimated that the other types of subsidies to farmers may contribute as much as another 25 percent to farmers' profits. Would consumers be willing to continue this expenditure to help agriculture and at the same time help farmers institute effective bargaining that would raise retail prices? Probably not. In fact, efforts on the part of farmers to force consumers to pay higher prices for food could result in a loss of the substantial public assistance now received to defray production and marketing costs. The willingness of the American public to finance agricultural research and education to insure a plentiful supply of food at reasonable prices has been the very root system of the success of our economy. Although consumers are the prime beneficiaries of these expenditures in the long run, the funds have been provided in the belief that they primarily aid agriculture.

The kind of bargaining that results in processors paying equal prices for equal quality to farmers in all locations (excepting transportation differentials) can be extremely beneficial for all concerned. But bargaining that forces processors and consumers to pay higher prices by reducing supply is an entirely different matter. Would the gains from "muscle bargaining" be sufficient to offset the possible loss of substantial income supplements farmers already receive through the generosity and good will of taxpayers? Would it be that subsidized agriculture is now in a position when it should ask: Do farmers really want to bite the hands that feed them?

CALORIC COST OF RICE AND WHEAT PROGRAMS[*]

A question that often faces those concerned with federal programs for farm commodities is government costs. An official of the U.S. Department of Agriculture, for example, in May of 1965 in his opening statement to a Congressional committee declared that the question to be considered was “how to reduce the costs of the rice program to bring it somewhere comparable with costs of other commodity programs” [4, p. 6]. The official was thinking in terms of government costs per acre (Table 1). Should programs emphasize one commodity rather than another simply because government cost per acre is more for the latter? An alternative and useful method of comparing government program costs for certain commodities can also be obtained on a caloric basis.

The 49,313,000 acres of wheat harvested in the United States in 1965 produced an average of 1,614 pounds per acre, while the 1,793,000 acres of rough rice harvested produced an average of 4,291 pounds per acre [3, pp. 30 and 68].[1] A pound of whole wheat contains about 1,497 calories; a pound of brown rice, 1,633 calories [5, pp. 108 and 120]. To convert rough rice to brown rice, the hulls—about 17 percent of the weight must be removed [1, p. 2]. Thus, a pound of rough rice contains about 1,356 calories.

When viewed in this light, government program costs for the 1965 crop were 1.84 cents per 1,000 calories of wheat produced and 1.12 cents per

Table 1. Government program costs for rice and wheat, 1966

Cost items[a]	Cost per acre		Cost per 1,000 calories	
	Rice	Wheat	Rice	Wheat
	dollars		cents	
Price support, net realized loss[b]	7.21	4.30	.12	.18
Commodity export, net loss	23.64	3.24	.41	.13
Public Law 480, Title I	31.13	19.80	.54	.82
Public Law 480, Title II	—	2.58	—	.11
Public Law 480, Title IV	3.43	4.10	.06	.17
Diversion payments[c]	—	.77	—	.03
Certificate program	—	9.67	—	.40
International wheat agreement	—	.21	—	.01
Total	65.42	44.54	1.12	1.84

[a] Among government costs not included are overhead, soil bank payments, and certain ocean transportation on foreign donations.

[b] Includes program as reported and interest in the amount of $196,000 for rice and $39,545,000 for wheat as estimated by the writers at 4 percent on the average investment in CCC grain.

[c] Includes $12,000 loss from the 1962 and 1963 Wheat Stabilization Programs.

[*] We acknowledge with gratitude comments and suggestions from Dr. Harvye F. Lewis and Dr. Shiang Ping Yang, both professors of home economics at Louisiana State University in Baton Rouge.

[1] Wheat production was converted from bushels to pounds at the rate of 60 pounds per bushel.

1,000 calories for rice—about 64 percent greater for wheat than for rice.

At present, government programs for rice are much simpler than for wheat. Rice has no cost in diversion payments, the certificate program, the International Wheat Agreement or Public Law 480, Title II, whereas costs to the government for wheat under these programs amount to .555 cents per 1,000 calories.

Wheat and rice are both involved in the price support program, the commodity export program, and Public Law 480, Titles I and IV. On a per calorie basis, program costs for wheat exceed that for rice in every case except the commodity export program.

Some may contend that the certificate program is not a cost to the government since a tax ultimately paid by consumers was simultaneously imposed at the beginning of this program to recover its cost to the government. If this program were eliminated from the above analysis, however, government costs for wheat would still amount to 1.44 cents per 1,000 calories compared to 1.12 cents for rice.

It is conceivable that some of the costs should not have been allocated to wheat and rice in the first place. Food for peace, repayments by recipient countries under Public Law 480 sales, maintenance of employment in the agribusiness sector of the economy, a favorable balance of payments position, maintenance of farm income and lowering prices to consumers are also important objectives of government programs. To the extent that costs are already being or will eventually be recovered through these objectives, they should not be allocated to the commodities. Further analysis is needed on these points.

Another question that might be raised concerns the desirability of various commodities. Meat, for example, is more desired, and people are generally willing to pay more for it than for other sources of protein. Similarly, rice is highly prized by many people throughout the world as a quality source of protein and for other reasons.

MILK PRODUCTION AND UTILIZATION IN THE EAST

Prospects Ahead for Milk Production

Milk production is really a mixed-up picture in the East today. There are four states in this group of 13 where milk production is declining sharply: Rhode Island, Delaware, West Virginia and New Jersey. Milk production in these 4 states combined dropped 17 percent between 1960 and 1965 and another 17.8 percent between 1965 and 1968. The drop last year, in one year, was 6.7 percent. Production in these four states represented 5.5 percent of the total milk supply in the East in 1968, compared with 8 percent in 1960. The primary causes for these declines in West Virginia undoubtedly include the difficulty of putting together enough top grade land in a contiguous area to make a dairy farm enterprise of the efficient scale required today. In the other three states, urbanization is pushing land values beyond the point where one can afford to grow roughage. Concentrates can be imported but manure must be combined with roughage. Low unemployment creates farm labor problems as well as excellent opportunities for the dairy operator to change jobs. I can see no reason to expect milk production declines in these four states to slow down very much.

Maine and Massachusetts, with a combined milk supply in 1968 of about 5 percent of the East's total, have shown a decline of 10.8 percent since 1965. Both states may well show further declines in production, especially if the pending milk control legislative developments turn out unfavorably in terms of price. Maine has the smallest dairy farms in New England, and Massachusetts should soon be feeling the pressure of urban land values that has already hit Rhode Island and New Jersey.

Connecticut, with 2.6 percent of the East's milk production, has had excellent milk prices and has some excellent dairy land. Its production has held up very well so far. Connecticut has a population density of over 600 per square mile (next highest after Rhode Island, New Jersey, and Massachusetts), and excellent employment opportunities. Also, its high milk prices—72 cents per hundred-weight above New Jersey in 1967—may be affected by the pending United States Supreme Court case on nearby farm location differentials under Federal orders.

New Hampshire's production, although only 1.4 percent of the East's total, has also held up well. A couple of more good ski seasons like the past one, however, and a continued growth in the vacation-home trend could help start a big climb in land values and a milk production decline in this state.

The other five states—New York, Pennsylvania, Vermont, Maryland, and Virginia—are the big dairy states in the East, with 85.5 percent of the area's 1968 milk production. These states have lost a lot of small dairy farms in recent years, and they have serious farm labor problems. But their main dairy areas have not felt the urban land value pressure as much as other states in the East.

Let us suppose that the eight small states in the East continue to decline in milk production at the rate they did between 1967 and 1968—about 4.42 percent or 175 million pounds of milk. The big five would have to show an increase of about 8/10ths of 1 percent in order to make this up. Instead, the five big states themselves showed a drop in milk production of 1.85 percent from 1967 to 1968, or 420 million pounds. Milk prices are good in these states in relation to feed prices. As long as unemployment is so low, the farm labor problem will remain serious. One hesitates to suggest that milk production may start to show increases again. Given a little longer range, with unemployment at 4.5 to 5.0 percent instead of 3.3, the big 5 states could make up the decline in the smaller states.

Utilization Changes Ahead

How about prospective changes in the utilization of the milk supply in the East? There are definitely three developments on the horizon in the East that are not good news for the butter industry. First, the fluid whole milk in the area, based on data available from the five major federal order areas, is still generally 3.55 percent milk or higher. Outside of the South and the West Coast, most of the other Federal orders show a prevailing fat test of 3.40 to 3.45, and below 3.4 in several cases. The East could certainly move its whole milk test down to 3.5 relatively soon. If this were done with no change in the farm test, it would release 8,050,000 pounds of butterfat or roughly 10 million pounds of butter.

Second, the major milk markets in the East have not yet moved nearly so much into low-fat and skim items as markets in other sections, but they are headed that way. The March 1969 Fluid Milk and Cream Report shows for 1968 that, for the five eastern Federal orders referred to above, the low-fat and skim items were only 8.6 percent of the combined sales of these items and whole milk. In the other 65 markets in this tabulation, the low-fat and skim items were 17.5 percent of the combined total.

Hopefully, some of this low-fat sales volume is new sales, but certainly a big share of it is not. In these five major Federal order areas (Washington, D.C. area, Baltimore area, Philadelphia area, Connecticut, and the Massachusetts-Rhode Island-New Hampshire area) sales of the low-fat items were up 237,000 pounds per day in 1968 over 1967, while whole milk sales were down in these markets 150,000 pounds per day.

Every 5 percent of our whole milk sales volume in the East that moves from 3.5 percent milk to 1.0 percent milk represents a release of 20,125,000 pounds of butterfat that will probably wind up in the churn. Changes of this proportion, or much greater, are definitely in the wind.

Third, the excellent fluid cream sales volume we have enjoyed for so many years in the East, while still almost unbelievably high in relation to other sections, is declining sharply. But non-butterfat substitutes and diets are still hurting. The sales volume of cream and half-and-half in the five big Eastern Federal areas in 1967 was 2.6 percent of the combined volume of whole milk and low-fat items, compared with only 2.0 percent in the other 64 market areas reported. Actually the difference is much greater than this on a butterfat basis because in these Eastern markets 65 percent of the volume was cream and 35 percent half-and-half, while the proportions were almost reversed in the other 64 market areas in this tabulation.

The main point is, however, that the 1967 to 1968 decline in the five Eastern areas for these cream and half-and-half items was 6.8 percent compared with 3 percent in the other

64 market areas. A decline of 7 percent in the amount of milk needed to produce the fluid cream and half and-half sales in the East releases about 5,000,000 pounds of butterfat per year for the churn.

There is every hope in the East that the need of butterfat for ice cream will be going up about 3 percent per year. This could just about offset the decline in the butterfat needed for fluid cream sales. However, this still leaves 28,175,000 pounds of butterfat released by fluid milk developments.

Dunbier, Roger, *The Sonoran Desert: Its Geography, Economy, and People*, Tucson, The University of Arizona Press, 1968, xiii + 426 pp. ($10.00)

Although the title of this book suggests a regional study, the author warns us at the start that "no attempt is made to show any overriding unity at work, geographical or otherwise. . . ." Here lies the work's main weakness: How can one write the geography, economy, and ethnology of a nonregion? This paradox is never resolved. Instead, the study is organized around two themes: that of man in relation to the physical environment of the desert; and, by contrasting modern southwestern United States with northwestern Mexico, that of the desert in relation to the social environment of man. Dunbier eventually defines his desert as the biotic province outlined by Shreve in 1951 (*Vegetation of the Sonoran Desert*) but extends it to include the coastal valleys south to the Río Culiacán.

In the development of the first theme, enough information is presented on landforms, climate, soils, vegetation, and water (chapters 1–5), and Indian, Spanish, and Anglo-American settlement (chapters 6–8) to fill in the geography and early economies for anyone not familiar with this part of the world. The emphasis here is on adaptation to, and exploitation of, the desert by the various groups that found themselves its willing or reluctant occupants. The section on vegetation provides a real feeling for the various communities, as well as all the common and Latin plant names.

A transition chapter on water resource development advances us to the period of massive environmental modification. Modern man does not adjust to the desert; he demolishes large parts of it by spreading water over thousands of acres and into densely populated cities and thirsty factories. Dunbier almost overdoes the data: a seemingly unending parade of river discharges, reservoir capacities, and irrigated acreages numbs the brain but does drive home the magnitude of change. Not just modification, but transformation! What is a desert with water? It is no longer a desert; so orchards bloom, cities spread, and populations multiply. The point is well made that in the desert it is not the land but the water that has value. And while some warn of future shortages, dwindling streamflows, and lowering water tables, is not the evidence that engineering will prevail?

The second theme is that modern landscapes cannot be explained in terms of local man-land relationships but must be viewed within the context of the larger societies that exercise political and economic control over them. Neither cotton from the irrigated fields of Sinaola nor electronics parts from the air-conditioned factories of Phoenix are possible or make sense without reference to the cultures that create first the demand for the products and then the physical environment in which they can be produced. The politically divided Sonora Desert makes an ideal laboratory for comparison. Following a long history of similar experience, sharp differences have developed on either side of the modern border due to the different rates of economic growth of Mexico and the United States. The respective cattle industries provide striking contrasts in organization and orientation. The sequence from native to Mexican to American economies (chapters 10-12) is a natural progression of increasing technological complexity and decreasing reliance on indigenous resources.

Chapter 13 on political factors takes a quick look at the fascinating border itself, "where the developed meets the underdeveloped world," and at the border towns with their unique functions and morphology. A short summary here should have ended the book; the final chapter on patterns of settlement adds little and is something of an anticlimax.

Technically the work leaves much to be desired. It is wordy and often redundant. Footnotes are excessive and inconsistent Maps lack geographic coordinates and scale. Dunbier does not appear to have personally inspected the nooks and crannies of either the desert or the archives: except for some government reports and published traveler's journals, there are few primary references in the 300-plus bibliography. The theme of man and the desert land, therefore, rests largely on recapitulations of previous work.

Furthermore, the relationship of the southwest to the U.S. economy is much better explained than is that of the northwest to the Mexican economy. This is reflected in the imbalance of source material: fewer than 10 percent of the citations are in Spanish and, while many of the English works are excellent, they are mostly written by Yankees. Thus, while a contrast of the two societies is central to the second argument, the view is decidedly from the North.

Hardin, Clifford M., ed., *Overcoming World Hunger*, Englewood Cliffs, New Jersey, Prentice Hall, 1969, xi + 177 pp. ($4.95 cloth, $1.95 paper)

Prepared before the editor became the Secretary of Agriculture, this book was background reading for the 34th American Assembly. As many readers will know, this unit of Columbia University selects important national and international issues and organizes a full three-day discussion program, bringing together a cross section of competent and interested participants. A number of regional Assemblies usually take place during the subsequent year, and this book serves these groups as well.

Obviously, having been developed as background papers, the book could be of major use in extension seminars and public policy discussions on international affairs and world food problems. It can be a key resource for such programs.

Following a brief introduction by the editor, four chapters constitute the book. Chapter I, by Frank Notestein, deals with population. Chapter II, by Don Paarlberg, discusses nutrition and food supply and the relative merits of trade versus national production. Chapter III, by J. George Harrar and Sterling Wortman, concentrates on methods by which food production can be increased. Chapter IV, by David E. Bell, Lowell S. Hardin, and F. F. Hill, gives attention to broad actions and policies by which population and food can be brought into balance, in the framework of the role and importance of foreign aid.

Competent and broad gauge professional and policy leaders, as these authors are, write competent and broad gauge monographs. For those already working in this area, the material is familiar. Only the measure of the authors' judgments on the future course of events will be of interest. For the non-specialist economist and agriculturist, the chapters are an excellent introduction and updating of food and population trends. A comprehensive picture is provided in less than 200 pages, including the view that food problems have the potential of being resolved, but only if broad, continuous effort is made across a spectrum of policies.

One weakness, relative to the purpose for which this book is designed, is the limited encouragement to further reading. The American Assembly does provide such lists to its participants; their inclusion would make the book more useful.

Chapter I is thoroughly competent. It reviews the methodology, presents the UN population projections, and discusses their validity. It presents and reviews action programs to reduce the birthrate. Notestein deals with a variety of relevant issues and, in appraising the prospects, insists that humanity must soon control its fecundity.

Chapter II is less tightly argued. Paarlberg shifts back and forth between the developed and the developing nations, which is sometimes confusing. He clearly states and supports the proposition that neither the problems nor the solutions can be stated simply. More attention than this reviewer deems appropriate is given to appraising P.L. 480, with too little on how income growth and its broader distribution can help resolve nutritional deficiencies. But Paarlberg emphasizes the need for increased national production.

Chapter III argues for an interdisciplinary approach in increasing the national production of food. True to the Rockefeller tradition, agricultural economics is virtually ignored. And much of the chapter describes and, by implication, prescribes the Rockefeller approach to expanding productivity. Accepting, as one must, that these programs did reverse the widespread pessimism of five years ago to cautious optimism, still these two leaders of the Foundation should be more aware than they appear to be of the new, though less onerous, problems that the increased productivity creates.

Chapter IV deals with the now necessary issues—why, how much, and in what way the United States and other developed nations should assist in supporting population control, agricultural expansion and economic growth. The discussion is relevant, responsible, competent, logical, but likely not to be persuasive to many members of Congress, unfortunately.

This little book fills a need for a single reference for the interested lay public. Extension economists will find it useful in many ways. Supplementing the text in a policy course, some students will start preparing for a term paper by reading part or all of this book. And the non-specialist will find in it reasons for cautious optimism that the Malthusian clouds could be cleared away.

LAWRENCE W. WITT
Michigan State University

Homer, Sidney, Paul W. McCracken, James J. O'Leary, and Henry C. Wallich, with a preface by Herbert V. Prochnow, *The Five-Year Outlook for Interest Rates*, Chicago, Rand McNally & Company, 1968, x + 89 pp. ($5.95)

Interest rates are in the limelight and for good reason: Be they the U.S. Treasury or just plain dirt farmers, borrowers in mid-1969 are paying rates previously seen only during national crises—the Civil War and War of 1812. Persons who consequently find themselves wanting or having to know more about the history, determinants, and prospects of interest rates will find this collection of four papers timely and informative.

The book is somewhat unusual in that each paper treats exactly the same subject. The sponsor—The Graduate School of Banking at the University of Wisconsin—evidently relied upon the varied background of the authors (two are primarily academic economists and the other two are Wall Street money-market analysts) to impart a different emphasis and style to each analysis. But as one might expect, there is agreement on and thus much repetition of the important points. And if the sponsor also expected significantly different opinions on the outlook, he was disappointed. One reads four times that rates in 1973 will probably be near historically high levels. Since there is no controversy either in analysis or the conclusion, the prospective reader may appreciate a plan of attack to avoid tedium.

A historical perspective should first be acquired, and an excellent starting point is right at the beginning of the volume with Homer's section on "The record of the past." Here one learns of the five great cycles in rates since 1800 and is disabused of any notion that movement in rates is something new or that rates move only in one direction. Then, for a detailed examination of factors responsible for the postwar upswing, skip to O'Leary's treatment of "The trend of interest rates since World War II."

One is now ready for an analysis of factors that will determine the level of rates five years hence, and here I recommend the McCracken paper. He presents a lucid discussion of the major considerations within a supply-demand framework, with both supplies and demands for funds conceptualized as proportions of national income. On demand, he emphasizes that a high rate of capital investment will be necessary to create jobs and provide housing for the now-maturing postwar baby crop and that federal expenditures on social problems will likely absorb more funds. On the supply side, he documents a historically stable savings rate, notes that the large number of young households to be formed over the next few years will contribute less to supply than to demand, and believes that probable continued price inflation will discourage suppliers of funds by reducing the "real" rate of return. (He expects continued inflation to result from greater public emphasis on maintaining a relatively low unemployment rate, which requires the economy to operate with less slack.) If both demand and supply schedules are expressed as proportions of a growing national income, he sees the demand schedule shifting to the right while the supply schedule is stable or actually moves to the left. The result: a price of money "high even by standards of the postwar period."

For those who want an analysis that goes beyond these principal factors, Wallich provides discussion of the different types of capital spending, the role of expectations in the term structure of rates, the impact of balance-of-payments considerations, and the effect of ongoing structural changes in capital markets. The observations of Homer, the respected bond market analyst, cover some of the same topics in readable fashion. But do not read Homer for rigorous analysis. He takes a long look at future demand and supply, but concludes that "Alas for the forecaster who seeks an easy tool, the total of savings in any one year always equals the total investment." Apparently, the concept of supply and demand schedules is not a prerequisite for success on Wall Street.

The authors forecast continued high interest rates, but remember that they wrote in 1968, when rates were considerably lower than in mid-1969. In taking on assignments to discuss the five-year outlook, they by-and-large excused themselves from discussion of short-term cycles. However, it is evident they did not expect that accelerated price inflation would within six months result in severe Federal Reserve restraint on expansion of bank credit and the money supply. Even from the 1968 level of rates, O'Leary expected a short cyclical downturn following a Vietnam peace. Presumably, the recent sharp rise gives this potential downswing a greater probable range.

The shorter cycles may be important to individuals faced with capital outlay and refinancing decisions, but it is the trend that bears most significance for agriculture. In 1968, interest paid by the farm sector totaled $3.0 billion, more than double the amount seven years earlier. However, the interest charge rose only slightly faster than the total debt. Now, as the expanding debt total is also refinanced at higher rates, the rise in total interest costs will accelerate.

A continued high level of rates may have other effects as well. In recent years, farmers' savings have provided a historically low percentage of the funds employed for equipment and land purchases, with increase in debt providing a historically high proportion. High interest rates may tend to reverse this trend. Also, the criterion that in theory governs investment decisions—the "capitalization rate" to be applied to an expected future income stream—will have changed, with perhaps some impact on the demand for land and other capital goods. But such possible effects must be broached with great caution, as numerous studies indicate that the rate of interest is only one of many factors involved in these matters, and that it has not usually been among the more important variables.

EMANUEL MELICHAR
Board of Governors of the Federal Reserve System

Iowa State Center for Agricultural and Economic Development, *Food Goals, Future Structural Changes, and Agricultural Policy: A National Basebook,* Ames, Iowa State University Press, 1969. x + 325 pp. ($5.95)

"This monograph was planned and written," the preface says, "to provide better bases for evaluating and formulating long-run policies for U.S. agriculture. The problems of agriculture with us today are largely the same as those of three decades back, just as are the policies which we employ . . . we could spend [another $60 billion] over the next fifteen years and still have the problem with us . . . should we look to other policy means and broaden the definition of the farm problem?"

The committee that organized the book arranged for 14 papers to be prepared on such topics as the world food situation, structural changes in agriculture, farm price and income programs, political forces in agriculture, goals, equity problems, noncommercial farmers, rural communities, and export policies. The 20 authors and co-authors, most from Land-Grant universities, are well-known in the field of agricultural policy. The problems most emphasized are (1) the threat to commercial farm income represented by excess capacity, (2) the virtual necessity of further drastic reduction in farm numbers and population, with attendant human problems, (3) declining economic opportunity facing many nonfarm rural people, (4) the difficulty of providing adequate services in rural communities, (5) a high incidence of poverty in many rural areas, and (6) the need of poor countries for food assistance.

Policies favored in the book are not new as proposals, but putting them fully into effect would greatly change the emphasis of agricultural and rural policy. Support for education in rural areas would be much enlarged. Labor mobility would be increased by training in nonfarm skills, improved employment information, and relocation subsidies. Farmers on inadequate units would be eligible for early social security payments. Welfare payments and services to indigent unemployables would be stepped up. Efforts for rural development would be organized around the functional unit concept, more aid in community planning would be provided, and loans and grants would be selectively available for installation of service facilities. Abroad, the United States would provide food aid as support for self-help by poor countries and would pursue liberal trade policies to expand markets for farm products.

What policy for commercial farming would be if the authors had their way is, not surprisingly, somewhat ambiguous. Kaldor, Ogg, and Saupe, taking long-run improvement of the economic performance of agriculture as their objective, hope that resource adjustments eventually will permit price and storage programs to be operated mainly for stabilization purposes rather than for income support. Hathaway concludes that the total program in effect in the late 1960's is workable, politically tolerable, and will not suffer a quick demise. Castle and Butcher say that output control is necessary but that land withdrawal is an unsatisfactory way to do it. Tweeten thinks that dissatisfaction with farm programs "will lead to an effective organization of farmers themselves to regulate production and marketing in perhaps 20 years."

Though the book repeatedly describes the changing number and size of farms under the impact of new technology, it does not convey much impression of the ways in which farming is being knit more closely into the industrial economy. Almost nothing is said about vertical integration or competition from synthetics. Corporate ownership is too little discussed. The prospect that hired farm labor will be employed on industry-like terms, mentioned briefly from a welfare standpoint, is not discussed at all for its impact on the structure and behavior of commercial agriculture.

The book represents orthodox thought among agricultural economists on the topics it covers, which is presumably what a "basebook" should do. Most of the articles will make good reading references in policy courses; an article by Maddox on noncommodity programs should be especially useful. But it must be said that the book is largely a re-do of things that have been done several times before, is likely to have little impact on professional thought, and is not written in a style attractive to the general public.

G. E. BRANDOW
Pennsylvania State University

Mathew, E. T., *Agricultural Taxation and Economic Development in India*, London, Asia Publishing House, 1968, 204 pp. ($7.50)

This short book originated as a doctoral dissertation at Vanderbilt University in 1964. While it suffers from some of the defects of most dissertations—such as unnecessary citation of not always relevant authorities—on the whole it is one of the better examples of this genre. Dr. Mathew has not only read most of the scanty decent literature on agricultural taxation in India (or anywhere); he has also thought about it critically, and, what is more important and unusual, he has attempted to appraise empirically its relevance to India today. His book can therefore be recommended as a useful concise introduction to a complex subject.

The principal empirical work attempted in the book concerns the relative "burden" imposed by the present Indian tax system on the agricultural and nonagricultural sectors. Unsurprisingly, the principal result of this laborious exercise is that the burden of taxation is heavier on the nonagricultural than on the agricultural sector. In particular, the higher-income groups within the agricultural sector are, Dr. Mathew concludes, "undertaxed" relative both to those of comparable income levels outside agriculture and to low-income agriculturists. While the author might well have exercised even more skepticism than he did in his use of data from the National Sample Survey and other Indian sources, there seems no reason to doubt that his calculations, given available information, are useful and generally sound. What is much more questionable is this whole approach to the admittedly important question of the "incidence" of taxation. "Tax-burden" tables of the sort painstakingly constructed by Dr. Mathew, even apart from the inevitably disputatious nature of the assumptions needed to construct them, cannot really give us any useful information about the distribution of the tax burden because of the falsity of the basic underlying assumption that the existing distribution of income (before tax) would be the same if the tax system did not exist. This is not to deny that comparison of two such tables might not yield useful information on the distributional effects of potential tax changes, a purpose for which Dr. Mathew's work (like other recent burden studies) should prove useful, but it does mean that such statements as "per capita net burden . . . forms 3.22 percent of the per capita income of an agriculturist in India" (p. 49) have no real meaning.

Dr. Mathew's own recommendations for the reform of agricultural taxation in India are closely related to those of such earlier writers as Hicks, Kaldor, and Wald. In essence, he would convert the present land revenue system (which is he notes, for the most part little more than a crude acreage tax) into a tax based on "the potential income from each holding under average conditions of production . . . estimated on the basis of a soil classification according to productive capacity" (p. 145). This tax should he argues, "take on as many features of the income tax as possible" (p. 1[illegible])—aggregation of all household holdings, personal exemptions, progressive rates, exemptions of particular forms of saving, etc., are therefore all recommended. Certainly no one can criticize Dr. Mathew's proposals as "too simple," "too crude," or "too arbitrary," to use some of the phrases by which he characterizes earlier reform proposals by the Taxation Enquiry Commission, Groves and Jadhaven, and others. Indeed, a major problem with the recommended system is almost surely that it is not simple and arbitrary enough. Like most authors, Dr. Mathew appears to underrate greatly the cost and difficulty of assessing potential output in India (or anywhere) in relation to the benefits to be gained in terms of increased tax revenues or agricultural productivity. The ease of evasion is also underestimated. After all, a principal reason for the present inadequacy of the Indian land tax system is the debility of the administration, so it is surely incumbent on those proposing new and more complicated systems to undertake a serious examination of the land tax administration and its potential for improvement, for an ideal tax badly administered may well be of less than a simple, crude, and arbitrary tax badly administered, if that is the choice.

The other principal reason for the relatively light taxation of agriculture in India is of course political. Like most economists, the author does not discuss this crucial factor sufficiently to justify much confidence in the future of his proposals. Incidentally, it is most curious that he rejects (p. 107) the policy of keeping agricultural prices low relative to nonagricultural prices as an alternative way of "taxing" the agricultural sector precisely on administrative and political grounds, when, as suggested above, it is these very factors, which he does not even discuss, that make his own proposed tax solution appear dubious.

Finally, one technical point might be mentioned: Dr. Mathew proposes that special assessments (irrigation and betterment duties) be dropped if his proposed system is adopted because their function will then be adequately served by the combination of land tax assessment based on potential yield and proposed capital gains tax on sales of land (p. 147). This is not the place to pursue the argument, but this recommendation reveals some confusion on the appropriate relative roles of the capital gains tax, the land tax, and special assessments, and there is in fact still an important potential role for the latter even in a Mathew-type ideal tax system.

RICHARD M. BIRD
University of Toronto

Sewell, W. R., and Blair T. Bower, eds., *Forecasting the Demands for Water*, Ottawa, Canada, Department of Energy, Mines and Resources, 1968, xiv + 262 pp. ($1.50 paper)

The main body of this work consists of five papers dealing in turn with the forecasting of municipal, industrial, agricultural, recreational, and in-stream water demands. These papers were originally presented in a seminar held in Vancouver, B.C., in December, 1967. In addition, the volume contains an introductory chapter, a second chapter that develops a conceptual framework for water resources planning, and a final chapter that considers the sectoral papers in a Canadian setting.

In the introduction, the editors take the position that the widely used "requirements" approach, in which no input substitutions involving water are allowed, is unacceptable as a procedure for predicting water needs. Their position is summarized as follows: "The requirements approach rarely considers the effects of price and sacrificed alternatives, and rarely takes adequate account of the impacts of possible technological changes, improvements in water use efficiency, and public policy decisions relating to water utilization." As would be expected, this theme is central to most of the methodological discussions. However, the distinction between "requirements" and "demand" is not always clear. The two introductory chapters serve their purpose adequately, but there are several carelessly defined concepts in the introduction that the reader may find distracting; e.g., "At very low prices, individuals would take all they could possibly use, but as the price increases, the quantities demanded fall off rapidly. This relationship is referred to as the price elasticity of demand for water, in conventional economic jargon."

The five main papers develop their respective topics in a straightforward manner and, in so doing, review and summarize current literature. For the most part, these papers break little new ground but offer discussions of their respective topics that range in quality from good to excellent; and if the critiques are included as part of each paper, I consider them all exceptionally good. Although I am not familiar with two of the topics, I would judge Charles W. Howe's paper on "Municipal Water Demand," Blair T. Bower's paper on "Industrial Water Demand," and Allan C. R. Albery's paper on "In-Stream or Flow Water Demand" the best. My main objection to the paper on "Agricultural Water Demand" is that it does not even mention what I have come to consider the pioneering work in this area. The Beringer [1] and Moore [2] research of the early 1960's developed production functions for water based on the soil-moisture-plant system. These functions can be aggregated over farm units for regional relationships. The critique by Blair T. Bower considers the micro-macro aspect in a little more detail but still does not offer any significant insight. The "Water Based Recreation" paper by Peter H. Pearse should have been more explicit in discussing forecasting methods because this was the purpose of the seminar. However, the paper reads well; and if a reader is interested in specific methods, it is well referenced.

In my view, the value of this work is as a first reference for practicing resource economists who may be called upon to forecast water demands. In addition, I feel that a well designed intermediate or advanced resource economics course should include work in this area since a significant amount of water resources research is concerned with forecasting demand. Considering its price, quality, and range of topics, the present volume seems to have all of the necessary attributes of a supplemental text.

HOWARD C. HOGG

Talbot, Ross B., and Don F. Hadwiger, *The Policy Process in American Agriculture,* San Francisco, Chandler Publishing Co., 1968, xii + 378 pp. ($8.50)

"Our primary objective in writing this book," declared the authors, "was to try to develop a broad conceptual framework whereby students in courses in American government and politics, as well as those in introductory courses in agricultural economics and policy courses, could see why and how one important area of public policy has developed and changed over decades of time" [p. xi]. In carrying out their task, they have produced a well-organized, documented, readable analysis that offers fruitful insights into some of America's hallowed political and governmental institutions. This book, coming at a time when our system of government is being confronted with a major challenge from within, should prove useful and interesting, not only to students, but also to those who serve as actors or audience in the drama of American politics and government.

The central thesis of the book is, in the words of the authors, "that disagreements over farm policy flow from the sharp ideological and materialistic conflicts within American agriculture, and will continue to do so for the next few decades" (p. 1). Identifying the quest for power as the major variable in the political behavior of farmers, the authors trace the political and policy landmarks in American agriculture from the seedtime of the Republic to midpassage of the twentieth century.

Professors Talbot and Hadwiger have identified two philosophical strains in the mind of the American farmer: (1) Jeffersonian agricultural fundamentalism, with its ideological commitment to liberty, freedom, equality, grass roots democracy, and the family farm; and (2) the Hamiltonian ideology of aristocracy, elitism, earned wealth, private property, and the commercial farm. The pendulum of politics is, in part, a continuing ebb and flow within the parameters of this ideological dichotomy, and it is reflected in a "game of political musical chairs" in which the modern Jeffersonians and the modern Hamiltonians take turns in commanding the policy machinery of the U.S. Department of Agriculture (p. 37).

The cloak of ideology, however, hangs loosely on the American farmer. The authors see him also as a pragmatist in which his interests—diverse and sometimes contradictory—lead him often to play the role of Madisonian realist in promoting and supporting public policies that he believes will maximize his material interests and political power, sometimes irrespective of his ideological commitments. "He searches for both truth and power," the authors have written, and his "theology has to be molded to fit into his sense of capitalism; his mind has to reconcile the conflicts, if any, between his heart and his pocketbook" (p. 64).

Utilizing such slippery concepts as power, legitimacy, leadership, grass roots democracy, public interest, and national purpose, the authors have traced, in depth and with insight, the farmer's quest for power. The trail leads through the political parties and the voting booth, the farm organizations and their lobbies, the Presidency and the executive establishment, the labyrinthian bureaucracy of the U.S. Department of Agriculture, the Congress and its committee system, the Supreme Court, the institutions of the federal-state system, and some of the relevant agencies of American foreign policy. The trail also leads through an analysis of the whole range of agricultural policy issues and subissues that have preoccupied the attention of the farmer and his representatives during the present century.

The title of this book is accurate, in part. The book does examine, primarily from a historical point of view, many of the institutions, personalities, and other input factors in the system, and it does examine the major policy products. However, at this stage in our progress as social scientists, we have come to expect that a study of the policy process in American agriculture might be more deeply concerned than is this book with the process itself. Models of decision-making, theories of individual and collective choice, the nature and limitations of rationality and rational action, the role of information, relevant and meaningful criteria for policy evaluation—these are some of the vital topics that one might expect to receive considerable attention in a book dedicated to the development of a broad conceptual framework for the understanding of the process through which agricultural policy is formulated. For those readers who subscribe to a more "behavioral" persuasion, this book will probably be viewed not as a study of the policy process but rather as an analysis of institutional anatomy.

This modest sense of disappointment having been expressed, it should promptly be emphasized that there is much in this very useful and interesting volume that goes beyond mere institutional description and anecdotal recital. For instance, in their "whirlpool-counterwhirlpool" concept of bureaucratic power, the authors introduce a notion that seems to carry us a step closer to meaningful empirical testing of the concept of institutional equilibrium. Similarly, they make a contribution to the development of a "policy science" with their concept of "subissues"—that is, "the struggle for both change and the status quo that goes on within the main issue . . ." (p. 206). Furthermore, the authors should be congratulated for refusing to be trapped into evaluating agricultural policy and process in terms of that old familiar test, "the public interest." Their idea of a contest between a "policy creed" and a "democratic creed" struggling to determine the policy content of something called "the national purpose" offers a fruitful alternative to that befuddled notion, "the public interest."

In a provocative final chapter, Professors Talbot and Hadwiger appropriately examine such highly relevant issues as hunger and food production, poverty, the need for a rural renaissance, the coming shortage of land, the quantity and quality of rural education, and the question of how the national purpose can be served as long as the policy-making institutions in agriculture, especially the USDA, remain pawns in the game of political pluralism. Carefully avoiding definitive answers, the authors effectively convey the sense of complexity that permeates the making of policy in agriculture, and they place appropriate emphasis on the interplay between the forces of change and the forces of continuity in the American system.

Announcements

WINTER MEETING
AMERICAN AGRICULTURAL ECONOMICS ASSOCIATION
WITH
ALLIED SOCIAL SCIENCE ASSOCIATIONS

December 28-30, 1969, New York City

SUNDAY, DECEMBER 28

9:00 a.m. **Macro-Simulation Models (Joint Session ES and AAEA)**
Chairman: George G. Judge, University of Illinois
Macro-Simulation Models—Specification and Evaluation of the Alternatives: Thomas H. Naylor, Duke University
Simulation Models as a Planning and Decision Tool for Developing Countries: A. N. Halter, Oregon State University, and Thomas J. Manetsch, Michigan State University
Discussants:
Richard Day, University of Wisconsin
E. P. Holland, World Bank
Glenn L. Johnson, Michigan State University
David Kresge, Harvard University

MONDAY, DECEMBER 29

10:30 a.m. **Current Economic Policies—Their Appropriateness and Effectiveness (Joint Session AEA and AAEA)**
Chairman: Dale E. Hathaway, Michigan State University
A Panel Discussion with Audience Participation
Panel:
Walter H. Heller, University of Minnesota
D. Gale Johnson, University of Chicago
John A. Schnittker, Kansas State University
Henry C. Wallich, Yale University

1:00 p.m. **Luncheon—AAEA**
Speaker:
John A. Hannah, Director, Agency for International Development

TUESDAY, DECEMBER 30

9:30 a.m. **Meeting the Changing Need for Agricultural Statistics**
Chairman: Joseph Ackerman, Farm Foundation
Social Change and Public Policy in Rural America: Data and Research Needs for the 1970s: J. Patrick Madden, Pennsylvania State University
Discussant:
Nathan M. Koffsky, Washington, D.C.
Changing Structure of Agriculture and Resulting Statistical Needs: Wesley B. Sundquist, ERS, USDA
Discussant:
Harold O. Carter, Council of Economic Advisors, Washington, D.C.

NOMINATING COMMITTEE, 1970-71 AAEA OFFICERS

In accordance with Article VII of the constitution, with the concurrence of the Executive Board, I have appointed the following persons as members of a committee to nominate persons to fill vacancies in offices of the Association for the year beginning August 1970.

Any member of the Association is eligible, and is invited to submit suggestions as to nominees to Dr. Breimyer as chairman, or to other members of the committee. Dr. Breimyer's address is Department of Agricultural Economics, 200 Mumford Hall, University of Missouri, Columbia, Missouri 65201.

Harold F. Breimyer, ex officio, *chairman*
Harold G. Halcrow
W. Keith Bryant
Joseph Willett
Charles R. Pugh

Dale E. Hathaway
President

AAEA DISTINGUISHED EXTENSION PROGRAM AWARD

To encourage the development of excellence in Extension economics work, the American Agricultural Economics Association will offer two awards of $250 in 1970. The award will be known as the Distinguished Extension Program Award. (The number of awards will be limited to one, unless the number of entries exceed ten.) Nominations for the award may be made by any member of the American Agricultural Economic Association and selection will be made from among those nominated. An individual may be nominated or two or more individuals may be nominated jointly. The purpose of the award is to recognize an outstanding program achievement, not to recognize an individual or individuals for noteworthy service as Extension economists over an extended period of time.

Each nomination must be made by separate letter to the Extension Award Selection Committee by March 1, 1970, accompanied by four copies of documentary evidence of the achievement of the person or persons nominated. Documentary evidence should include an adequate presentation of the following points, in this order: (1) names(s) and titles(s) of the person or persons nominated; (2) the problem about which the person or persons nominated built their Extension program and the objective(s) of the program; (3) clientele served; (4) the program developed to attain the objective(s), including analytical tools and techniques, and education methods and procedures used; and (5) program accomplishments in terms of clientele response and/or establishment of the validity of an Extension technique. If two or more persons are nominated jointly, the specific contribution of each to the Extension program. must be documented.

In order to be eligible for nomination, an individual or individuals must have had primary responsibility for the Extension program that supports the nomination. The program must have been active within one year of the date of nomination, and its subject matter content must be principally in the field of economics.

Each nomination will be evaluated on the quality of the program that supports the nomination, using the documentary evidence submitted with the nomination as the sole basis for making this evaluation. Equal weight will be given each of the following five characteristics of the program:

1. Its effectiveness as a catalyst to other Extension economists in embarking on new programs or in applying new concepts to existing programs.
2. Its contribution to greater proficiency of Extension personnel in economics programs.
3. Its effectiveness in bringing about a significant change in behavior and/or understanding of the clientele.
4. Originality in recognizing educational opportunities which lend themselves to solution by an Extension economics program.
5. Originality in the application of economic principles and tools of analysis to problem-solving situations in Extension.

Material should be sent to subcommittee chairman, Stephen J. Brannen, Department of Agricultural Economics, University of Georgia, Athens, Georgia 30601.

AAEA DISTINGUISHED UNDERGRADUATE TEACHER AWARD

To recognize and encourage meritorious performance in undergraduate teaching in agricultural economics, an award of $250 is provided for presentation by the American Agricultural Economics Association upon recommendation of the selection committee. Nominations for this award may be made by an individuals, a group of colleagues, or a department of agricultural economics by the submission of supporting materials according to the rules for this program. Renomination is invited if the materials are brought up to date and resubmitted.

Eligibility for Nomination

The nominee must

1. be actively engaged in teaching during the school year in which the nomination is filed with the selection committee, and have been actively engaged in teaching for not less than five years;
2. have demonstrated outstanding ability as an undergraduate teacher of agricultural economics subject matter.

Basis of Selection

The award will be made on the basis of

1. the nominee's ability to motivate and stimulate students;

2. the impression he has made upon his students by the mastery of his subject, his technique, his vision, and his attitudes;

3. evidence of his interest in the improvement of teaching through publication and participation in professional meetings directed toward improved teaching;

4. contribution to undergraduate education outside of the classroom through counseling, student placement, advice to the department student club, and similar activities;

5. service to the undergraduate program of the educational institution through extracurricular activities other than those included above, such as membership on college committees, teaching improvement efforts, and faculty leadship roles.

Materials to be Supplied by the Nominator

1. Six copies of a biography of the nominee, not to exceed 1000 words.

2. Six copies each of letter in support of the nominee from not more than five former students.

3. Letters from at least one representative of the nominee's institution regarding the nominee's activities in the area defined in points 3, 4, and 5 under "Basis for Selection."

4. Six copies of a list of materials developed and/or published by the nominee related to undergraduate instruction. The list may cite the development of items useful in teaching, such as course outlines, curricula, books, research reports, visual aids, charts, models, or other contributions.

Nominations

1. It is desirable to make nominations without the knowledge of the nominee, when this does not interfere with submitting a complete file of supporting letters, materials, and a biography. A nomination with supporting materials may be submitted by another individual, a group of colleagues, or a department. Anyone submitting a nominee from another institution will be referred to the department head of that institution for a coordination of efforts, if found to be agreeable to the two parties involved.

2. Six copies of all supporting materials are to be in the hands of the chairman of the selection committee by March 1, 1970.

3. The selection committee for the Teacher Award consists of six persons, either present or former undergraduate teachers, appointed for staggered terms, and will not include anyone nominated for the award. All members of the selection committee participate in the judging. The selection committee is empowered to recommend that no award be made if, in their judgment, none of the nominees is worthy of the award.

4. *Nominations with supporting materials for the Teacher Award should be sent by March 1, 1970, directly to the chairman of this subcommittee,* Carroll V. Hess, Dean, College of Agriculture, Kansas State University, Manhattan, Kansas 66502.

AAEA AWARDS FOR RESEARCH IN AGRICULTURAL ECONOMICS

To recognize and encourage meritorious research in agricultural economics, 10 awards will be offered in 1970 by the American Agricultural Economics Association. Seven awards will be $250 each, and three, $100 each.

Selection for the awards will be made from published research, doctoral theses, master's theses, and articles in the *American Journal of Agricultural Economics* under the procedures outlined below. No one may receive more than one award in any one year, nor an award in the same category more than once every three years. No publication shall be eligible for an award if its substantive equivalent has received an award in any category in an earlier year. All materials submitted should be in English or accompanied by an English translation.

Awards for Published Research

1. Three $250 awards are offered for outstanding research publications in agricultural economics. These may include bulletins, articles, pamphlets, and monographs, but not textbooks. Joint authors of a winning report will receive proportionate shares of an award, so far as eligible.

2. Submissions are invited from areas such as farm management, marketing, prices, cooperation, finance, policy, theory, methodology, rural development, farm population, foreign agriculture, land and water economics, conservation, regional adjustment, international trade, economic history, state and local government, that throw significant light on the agricultural economy. Entries will be judged as a group rather than in particular areas.

3. Selections will be made from published research bearing a publication date in 1969.

4. Eligible recipients must be under 41 years of age at the time of publication, but may have older joint authors.

5. Any paper authored or co-authored by a member of this awards committee will be ineligible.

6. No penalty for joint authorship will be imposed unless one or more authors are over 41 years of age.

7. Each published report may receive only one award presented by the American Agricultural Economics Association in 1970. However, a report may be entered in more than one of the following categories: (a) Best article in the Journal of Agricultural Economics; (b) Published research; (c) Doctoral thesis; and (d) Master's thesis.

8. Thirteen copies of each publication should be submitted for consideration, unless expense to the individual is excessive.

9. The Awards subcommitte for published research consists of 12 persons in addition to the chairman, representing various fields. The members of the subcommittee will serve as voting judges, except the chairman, who will vote only in the event of a tie. The chairman of this subcommittee is G. Edward Schuh, Department of Agricultural Economics, Purdue University, West Lafayette, Indiana 47901.

10. *Publications should be sent directly to the chairman of this subcommittee before February 15, 1970.*

Awards for Doctoral Theses

1. Three $250 awards will be available for theses prepared by candidates for the doctoral degree in any department engaged in training agricultural economists at the doctoral level.

2. An entry must be submitted by the head of the department where the thesis was presented in partial fulfillment of requirements for a degree. A department may submit one thesis for each twelve doctoral theses or fraction thereof presented, in agricultural economics, to a graduate school faculty in the year. In determining the number of eligible theses, departments should limit consideration to theses of candidates who will receive a degree in agricultural economics and to theses of candidates who have taken agricultural economics as a field of emphasis.

3. Selection will be made from theses approved in final form by the student's advisory committee during the calendar year 1969, provided the candidate has met all other formal requirements for the doctoral degree.

4. A published thesis may be entered in both the published research and thesis classes but will be eligible for only one award. Although a published thesis is acceptable, a copy of the thesis as submitted to the graduate faculty should be sent whenever possible.

5. Three copies of a thesis must be sent to the subcommittee chairman. All copies will be returned after they have been read by the judges.

6. The awards subcommittee for doctoral theses will consist of twelve persons in addition to the chairman. All members of the subcommittee will serve as voting judges except the chairman, who will vote only in the event of a tie. The chairman of this subcommittee is Willard F. Williams, Department of Agricultural Economics, Texas Technological College, P.O. Box 4169, Lubbock, Texas 79409.

7. *Theses should be sent directly to the chairman of this subcommittee before February 15, 1970.*

Awards for Master's Theses

1. Three $100 awards will be available for theses prepared by candidates for the master's degree in any department engaged in training agricultural economists at the master's degree level.

2. An entry must be submitted by the head of the department where the thesis was submitted in partial fulfillment of requirements for a degree. A department may submit one thesis for each fifteen master's theses or fraction thereof presented to a graduate school faculty in the year. In determining the number of eligible theses, departments should limit consideration to theses of candidates who will receive a degree in agricultural economics, and to theses of candidates who have taken agricultural economics as a field of emphasis. Departments are strongly encouraged to submit either ribbon copies, in the case of typewritten theses, or Xerox or other processed copies of comparable quality.

3. Selection will be made from theses approved in final form by the student's advisory committee during the calendar year 1969, provided the candidate has met all other formal requirements for the master's degree.

4. Three copies of a thesis must be sent to the subcommittee chairman. All copies will be returned after the committee has completed its work.

5. A published thesis may be entered in both the published research and thesis classes, but will be eligible for only one award. Although a published thesis is acceptable, a copy of the thesis as submitted to the graduate faculty should be sent whenever possible.

6. The awards subcommittee for master's theses will consist of six persons in addition to the chairman. All members of the subcommittee will serve as voting judges except the chairman, who will vote only in the event of a tie. The chairman of this subcommittee is Eldon E. Weeks, Farm Income Branch, editorial council of the Journal of Agricultural Economics, with the editor as D.C., 20250; Phone 202-388-2242.

7. *Theses should be sent directly to the chairman of this subcommittee before February 15, 1970.*

Award for Best Article in the *American Journal of Agricultural Economics*

As has been the practice for a number of years, the editorial staff and the editorial council of the *American Journal of Agricultural Economics,* with the editor as chairman, will choose the most outstanding article published in the Journal during the preceding calendar year (in this instance, 1969). The amount of this award is $250.

Announcements of the 1970 awards will be made at the 1970 annual meeting of the American Agricultural Economics Association. Names of the recipients of the 1969 awards appear in the 1969 proceedings issue of the *American Journal of Agricultural Economics.*

These awards are financed in part from funds donated by persons and firms interested in advancing research and scholarship in agricultural economics. The funds and programs are administered by the American Agricultural Economics Association. General inquiries and requests for additional copies of this announcement should be sent to the chairman of the Awards committee, Emery N. Castle, Department of Agricultural Economics, Oregon State University, Corvallis, Oregon 97331.

WESTERN AGRICULTURAL ECONOMICS ASSOCIATION

The 1970 meeting of the Association will be held at Tucson, Arizona, July 19–22.

The Association has published a monograph entitled *The Western Agricultural Economics Association: Aspirations and Achievements,* by D. B. DeLoach. Association members will receive a copy of the monograph and nonmembers may obtain copies at $1.00 from Leo R. Gray, Secretary-Treasurer, Western Agricultural Economics Association, P.O. Box 89, Berkeley, California 94701.

OFFICE OF WATER RESOURCES RESEARCH

The Office of Water Resources Research is now accepting unsolicited research proposals in the field of water resources pursuant to Title II of the Water Resources Research Act of 1964, as amended. Although proposals may be submitted to OWRR at any time, those received after October 1, 1969, will be held for future consideration, i.e., for fiscal year 1972 or thereafter.

Detailed instructions and forms for the submission of proposals for consideration for funding under the Title II provisions of the Water Resources Research act may be obtained from the Director, Office of Water Resources Research, U.S. Department of the Interior, Washington, D.C. 20240.

TEXAS A&M UNIVERSITY

The Texas Agricultural Market Research and Development Center, a new research center in agricultural economics, has been announced by Texas A&M University. The Center has a program of marketing strategy research and education designed to assist agricultural groups and agribusiness firms in evaluating and solving their immediate and emerging marketing problems. The Center is a part of the Department of Agricultural Economics and Sociology.

Robert Branson, professor of agricultural economics, is directing this new research program. Other members of the department associated with the Center are William Black, extension marketing specialist; Chan Connolly and Randall Stelly, associate professors; John Nichols and Thomas Sporleder, assistant professors. Food technologists, statisticians, psychologists, sociologists, and other specialists are included in research task forces according to the nature of each marketing problem.

JOURNAL OF THE AMERICAN STATISTICAL ASSOCIATION

The *Journal of the American Statistical Association* is to be divided into two sections, "Theory and Methods" and "Applications," a change designed to stimulate the submission of more quality manuscripts applying statistical methods to substantive problems. Particularly desired are good manuscripts in social science. Robert Ferber, Applications Editor, states that "a major attraction of *JASA* to prospective authors about which you might care to know is its policy of publishing manuscripts, after acceptance, in the very next issue to go to press. Hence, *JASA* has no backlog." Manuscripts in the applications area should be addressed to Robert Ferber, Applications Editor, Survey Research Laboratory, University of Illinois, Urbana, Illinois 61801.

WESTERN AGRICULTURAL ECONOMICS RESEARCH COUNCIL

In August 1968 WAERC restructured its committee system into three groups, plus a provision for ad hoc committees to consider the emerging problems and issues as deemed necessary. The three new committees are: (1) Committee on Commercial Agriculture; (2) Committee on Natural Resources Development; and (3) Committee on Community and Human Resources Development. Functions of the new committees will be:

(a) To aid in defining important research needs and in developing means for meeting them.
(b) To stimulate and develop professional exchange among research personnel in our region.
(c) To develop specific research project proposals.

Lynn G. Sleight, MED at University of Illinois; **Thomas T. Stout**, on leave from Ohio State University, MED; **Abner W. Womack**, Long-Run Projections Section, Outlook and Projections Branch, ESAD; **Henry L. Wong**, Ph.D. Hawaii, 1969, MED.

Transfers: **John H. Droge**, MED from Madison to Washington, D.C.; **Opie C. Hester**, C&MS at Rosslyn, Virginia, from Poultry Section, Commodity Analysis Branch, ESAD; **John M. Himmelberg**, from Farm Income Estimates Section, Farm Income Branch, to Demand Analysis Section, Outlook and Projections Branch, ESAD; **J. Blake Imel**, MED, from Berkeley to Madison; **David A. Lins**, FPED, from Washington, D.C. to Urbana; **William C. Motes**, Director, EDD, from FEPS; **John B. Penson, Jr.**, FPED, from Washington, D.C. to Urbana; **Jerry A. Sharples**, FPED, from Washington, D.C. to Lafayette, Indiana.

Leaves: **Cecil W. Davison**, returned to FPED after three years in army; **Robert D. Reinsel**, returned to FPED after two years of graduate study, under Employees Training Act, at Michigan State University.

Resignation: **Arthur G. Conover**, as agricultural economist in office of the director, ESAD.

Awards: **Wesley B. Sundquist**, Director, FPED, and **James Vermeer**, FPED, USDA Superior Service awards.

UNIVERSITY OF FLORIDA

Appointments: **Wallace Kenneth Boutwell**, as assistant dean of faculties for resources planning; **James R. Conner**, Ph.D. Texas A&M, 1969, and **Kamal Dow**, Ph.D. Missouri, 1969, assistant professors.

UNIVERSITY OF IDAHO

Appointments: **Karl H. Lindeborg**, returned from sabbatical at University of Oslo, professor; **Edgar L. Michalson**, formerly with FPED, ERS, USDA, at Washington State University, associate agricultural economist, Water Resources Institute; **Robert L. Sargent**, formerly visiting associate professor, extension marketing specialist.

IOWA STATE UNIVERSITY

Appointment: **Charles P. Gratto**, associate professor.

Leave: **Lehman B. Fletcher**, faculty improvement leave (six months).

UNIVERSITY OF MASSACHUSETTS

Appointment: **Robert Vertrees**, Ph.D. candidate, Michigan State, teaching-research assignment in resource economics.

Retirement: **Ellsworth W. Bell**, after 40 years of service.

MICHIGAN STATE UNIVERSITY

Appointments: **L. L. Boger**, Dean, College of Agriculture and Natural Resources; **Dale E. Hathaway**, chairman of department.

Leaves: **John Ferris**, in England directing a study of agriculture of EFTA countries; **Donald Larson**, USAID, Colombia (one year); **Lawrence W. Witt**, Ford Foundation, Lahore, Pakistan (three months).

UNIVERSITY OF MINNESOTA

APPOINTMENTS: **Emiel W. Owens**, Prairie View A&M College, Texas, visiting professor in human resources (one year); **Herbert H. Stoevener**, Oregon State University, visiting professor in resource (recreation) economics (one year).

LEAVES: **Martin E. Abel**, Ford Foundation program advisor in agricultural economics, India (two years); **Reynold P. Dahl**, party chief, Minnesota-AID Tunisia project, Tunisia (one year); **John D. Hyslop**, returned from two-year assignment on Minnesota-Tunisia project; **Vernon W. Ruttan**, fall quarter, 1969.

AWARD: **E. Fred Koller**, Alumni Achievement Award, Augustana College, Sioux Falls, South Dakota.

UNIVERSITY OF MISSOURI

APPOINTMENTS: **Charles L. Cramer**, assistant chairman of the department; **Jack D. Timmons**, formerly of the University of Nebraska, instructor.

LEAVES: **J. Wendell McKinsey**, returned from five years of service as chief of party, India program; **Philip F. Warnken**, Ford Foundation, Sao-Paulo, Brazil.

NEW MEXICO STATE UNIVERSITY

APPOINTMENTS: **Shaul Ben-David**, formerly visiting assistant professor, Cornell University, associate professor of natural resources; **William D. Gorman**, formerly of Purdue University and Stanford Research Institute, associate professor, agricultural marketing and prices; **Garrey Edward Carruthers**, Ph.D. Iowa State, 1969, assistant professor in regional economics.

PURDUE UNIVERSITY

APPOINTMENTS: **L. M. Eisgruber**, assistant department head for research (three-year term); **H. A. Wadsworth**, assistant department head for extension (three-year term, beginning Feb. 1, 1970, after six-month leave at Oregon State University); **Larry P. Bohl**, Ph.D. Purdue, 1969, assistant professor.

LEAVES: **Julian H. Atkinson**, chief of party, Purdue-Brazil project, Brazil (two years); **Edward E. Carson**, University of California, Berkeley (six months); **Bob F. Jones** and **George F. Patrick**, returned from two years with Purdue-Brazil project, Brazil; **Don Paarlberg**, director of agricultural economics, USDA (one year); **T. Kelley White**, Purdue-Brazil project, Brazil (two years).

RETIREMENTS: **John B. Kohlmeyer**, after 44 years of service in Cooperative Extension Service and School Reorganization; **Harry W. Leonard**, after 32 years in agricultural education and economics.

AWARDS: **J. Carrol Bottum**, Hillebrand Distinguished Professor, Purdue University, and honorary Doctor of Science degree, South Dakota State University; **Emerson M. Babb**, Social Science Research Council Senior Research Fellowship for study in behavioral sciences, University of California, Berkeley (one year); **J. W. Judy, Jr.**, Outstanding Teacher award of Student Government; **Don Paarlberg**, Outstanding Teacher award of the university.

SOUTHERN ILLINOIS UNIVERSITY

Appointments: **Gordon Langford**, Ph.D. Montana State, 1969, assistant professor.

Leave: **Walter J. Wills**, Fulbright lecturer, Ege University, Barnova, Turkey (1969-70).

TEXAS A&M UNIVERSITY

Appointments: **William C. Brown**, on leave from Oregon State University, Texas A&M Contract team, Argentina, to train South American students in agricultural economics; **Robert E. Whitson**, M.S. Texas Technological College, 1969, extension area farm management specialist, Gonzales, Texas.

Leave: **Vance W. Edmondson**, returned from five-year assignment with National Institute of Agricultural Technology, Argentina.

Retirement: **Aden C. Magee**, as professor of farm management, after 42 years of service.

WASHINGTON STATE UNIVERSITY

Appointments: **Dennis Oldenstadt**, assistant director of Agricultural Research Center; **Kenneth Casavant**, Ph.D. candidate, Washington State, instructor.

Leaves: **Laszlo Valko**, international cooperative conferences and study of agricultural cooperative and credit systems in Germany, Switzerland, and Austria (three months); **Eldon E. Weeks**, ERS, USDA, Washington, D.C. (one year).

WEST VIRGINIA UNIVERSITY

Appointments: **Kenneth D. McIntosh**, acting director of newly created Division of Resource Management (including agricultural economics, agricultural engineering (research), and landscape architecture); **James H. Clarke**, acting chairman, Committee of Agricultural Economics, Division of Resource Management.

UNIVERSITY OF WISCONSIN

Appointments: **Charles W. Loomer**, Secretary of the Faculty, Madison; **Willard Mueller** of the Federal Trade Commission, Vilas Professor of Agricultural Economics; **William Dobson**, Ph.D. Purdue, 1969, and **Emil Haney**, Ph.D. Wisconsin, 1969, assistant professors.

OTHER APPOINTMENTS

Victor F. Amann, formerly of West Virginia University, senior lecturer, Makerere University, Kampala, Uganda.

Juan A. Aquirre, Ph.D. Cornell, 1969, academic staff, Inter American Institute of Agricultural Sciences, Turrialba, Costa Rica.

Donald Audt, Ph.D. Missouri, 1969, economist, Land-O-Lakes Creameries, Minneapolis.

George Brinkman, formerly of Michigan State University, assistant professor, Kansas State University.

Harold B. Brown, M.S. Purdue, 1969, Cooperative Extension Service, Ohio State University.

Joseph D. Coffey, formerly assistant professor, University of California, Berkeley, Planning Evaluation and Programming Staff, USDA, Washington, D.C.

Bruce W. Cone, Ph.D. Purdue, 1969, operational analysis and economics department, Battelle-Northwest.

Lee M. Day, department chairman, Pennsylvania State University, succeeding Macklin E. John, returned to teaching and research.

Ralph K. DeHaven, Ph.D. Missouri, 1969, assistant professor, Clemson University.

Danny C. Denton, M.S. Arkansas, 1969, instructor, University of Arkansas.

William D. Dobson, Ph.D. Purdue, 1969, assistant professor, University of Wisconsin.

Richard L. Duffy, M.S. Purdue, 1969, commodity analysis division, Pillsbury Mills, Minneapolis.

Roberto P. Echeverria, Ph.D. Cornell, 1969, economist, International Bank for Reconstruction and Development, Washington, D.C.

Mohammed Hassan Fag El Nour, Ph.D. Wisconsin, 1969, National Institute of Planning, Cairo.

Robert H. Elrod, Ph.D. Clemson, 1969, assistant professor, Georgia State College.

Robert E. Evenson, formerly of the University of Minnesota, Department of Economics and Economic Growth Center, Yale University.

Ernest Feder, formerly chief of agricultural section, ECLA/UN, Mexico, director of UN/FAO Institute of Land Reform, Ceylon.

Luis R. Flores, M.S. Purdue, 1969, Banco Nacional de Fomento, Enterprise Development Division, Tegircigalpa, D.C. Hounduras, C.A.

Richard J. Foote, professor in statistics and price analysis, Texas Technological College.

James R. Garrett, acting chairman, Division of Agricultural and Resource Economics, University of Nevada (Sept. 1969-June 1970), in absence of **John W. Malone, Jr.**, on leave as American Council on Education Fellow (Ford Foundation), Purdue University.

Wendell Gottman, M.S. Missouri, 1969, Tractor Operations, Ford Motor Company, Birmingham, Michigan.

Charles H. Greene, New Mexico State University, agricultural economist, American Sheep Producers Council, Denver (Jan. 1969).

Douglas D. Hedley, formerly of Michigan State University, agricultural economist, International Institute of Tropical Agriculture, Ibadan, Nigeria.

Robert W. Herdt, Ph.D. Minnesota, 1969, assistant professor, University of Illinois.

Aaron A. Hutcheson, Ph.D. Clemson, 1969, chairman, economics department, Austin Peay State University, Clarksville, Tennessee.

Ashmore Johnson, M.S. Purdue, 1969, government position, Kingston, Jamaica.

John W. Judy, Jr., formerly of Purdue University, head of veterinary medicine and surgery department, University of Georgia.

Amir Khalili, Ph.D. Missouri, 1969, assistant professor, School of Business Administration, Cleveland State University.

Carl B. Lewis, Ph.D. Nebraska, 1969, acting chairman of economics department, Kearney State College, Kearney, Nebraska.

Harold Love, Ph.D. Missouri, 1969, assistant extension professor, University of Kentucky.

Ben R. McManus, Ph.D. Purdue, 1969, assistant professor, University of Tennessee.

Euter Paniago, Ph.D. Purdue, 1969, returned to Purdue-Brazil project, Vicosa, Brazil.

Abdel-Hamid Y. Saad, Ph.D. Cornell, 1969, Ministry of Supply, United Arab Republic.

Lester Schmid, formerly of Land Tenure Center, University of Wisconsin, Southwest Minnesota State College.

Alvin Schupp, Ph.D. Missouri, 1969, assistant professor, Louisiana State University.

Ismail Sener, formerly of University of Nebraska, chairman of agricultural marketing department, Ministry of Agriculture, Turkey, and agricultural advisor of Turkish Permanent Delegation to EEC.

Mahfouz E. Tadros, Ph.D. Cornell, 1969, research associate in water resources, Cornell University (one year).

Jack Thornton, Ph.D. Missouri, 1969, associate professor, East Carolina State College, Greenville, North Carolina.

Benjamin Villanueva, formerly of Land Tenure Center of University of Wisconsin, economist in charge of price policy, SIECA, Guatemala.

Tae-Hee Yoon, formerly of Lakehead University, Ontario, senior economist, Planning and Evaluation Branch, Canada Department of Manpower and Immigration, Ottawa.

OTHER LEAVES

Loyd Fischer, University of Nebraska, one-year assignment in La Paz, Bolivia.

OTHER AWARDS

Vernon R. Eidman, Oklahoma State University (with **Harold O. Carter** and **Gerald W. Dean**, University of California, Davis), WAEA 1969 Certificate of Merit for outstanding published research (Giannini Foundation Monograph No. 21: *Decision Models for California Turkey Growers*, July 1968).

Hiroshi Mori, chief of international affairs section, Ministry of Agriculture and Forestry, Tokoyo, award at annual convention of Agricultural Economics Society of Japan for work in agricultural marketing done as visiting professor at Purdue University (with W. L. Gorman).

OBITUARY

Alois F. Wolf, 69, a former employee of USDA's Economic Research Service, died on June 24, 1969, in Edison, New Jersey, where he had been residing. Born in Germany in 1899, he received a B.S. degree in 1920 and an M.S. degree in 1924 from Teachers College in Breslau. He came to the

United States in the late 1920's and worked for USDA's AAA from 1934 to 1936. Then, until 1958, he was market Manager for the Dromedary Company, a division of the National Biscuit Company. For several years during this period, he served as a consultant to the Florida Citrus Mutual and the American Cranberry Exchange. Mr. Wolf returned to USDA in 1958 and worked as an agricultural economist until his retirement in 1966.

AGRICULTURAL MARKETING ECONOMISTS

are sought by the FOOD AND AGRICULTURE ORGANIZATION OF THE UNITED NATIONS for present and projected posts in developing countries.

IF YOU HAVE:

- —appropriate university degree
- —at least five years of research and/or practical experience in agricultural marketing economics
- —good working knowledge of English, French, or Spanish

WE CAN OFFER:

- —competitive tax-free salaries, based on depth and breadth of training and experience
- —other liberal benefits

Interested candidates should send full resumé to the Chief, Recruitment Section, FAO, via Cristoforo Colombo, 442, Rome, Italy quoting Ref. ES/RU/Mktg/OL. Formal application forms will be sent to suitably qualified candidates.

JOURNAL OF AGRICULTURAL ECONOMICS

New Editions of Classic Texts

The Nature and Properties of Soils, Seventh Edition
By the late Harry O. Buckman, formerly, Cornell University, and Nyle C. Brady, Cornell University

This classic text offers a complete introduction to the nature and properties of soils, especially as they relate to the growth of plants. The seventh edition is an updating of the entire book, reflecting the latest research findings in soils, and the following chapters have been completely revised: Soil Formation, Classification and Survey; Soil Colloids: Their Nature and Practical Significance; Soil Reactions: Soil Acidity and Alkalinity; and The Nitrogen Economy of Soils. A new section concerned with sulfur has been added. Numerous tables, diagrams, and photographs, including soil maps which employ the new comprehensive classification scheme, are presented.
1969, 653 pages, \$10.95

Modern Breeds of Livestock, Third Edition
By Hilton M. Briggs, South Dakota State University

Revised to reflect current developments and research, this fine text includes material on new and developing breeds, with particular emphasis on the shifting population of various breeds of livestock. Organized on the basis of an historical presentation and evaluation of each breed, the book is designed to acquaint the student with the special attributes and limitations which determine the past importance and future potential of the breeds of livestock generally found in the United States. Charts, tables, and illustrations have been extensively updated.
1969, 714 pages, \$12.95

The Canadian Journal of Agricultural Economics is published by the Canadian Agricultural Economics Society. Annual dues or subscriptions are $10.00. Address editorial communications to M. L. Lerohl, Editor, Agricultural Economics Research Council of Canada, Carleton University, Ottawa, Ontario, Canada.

World Food Production MUST KEEP PACE WITH RISING POPULATION DEMANDS or Famine Will BE WORLDWIDE!

WILL IT BE FOOD OR FAMINE?

A North American Common Market

proposes a solution!

A NORTH AMERICAN COMMON MARKET proposes a plan to meet this mounting crisis. This just-published book offers a method that can answer the problem of U.S. food surpluses vs. hunger in the world. FURTHER, it recognizes the existence of trade and political barriers and offers a solution.

A NORTH AMERICAN COMMON MARKET examines future potentials of food production in Canada, the United States, and Mexico.

PROBLEMS and possibilities of increasing this source of food supply are examined under conditions where (a) only commodities could flow into a common market without trade barriers and (b) both commodities and resources could flow among agricultural regions and countries under these conditions.

PATTERNS of resource allocation, production location, and market floors would be allowed to spread over the entire continent in the most efficient manner.

ECONOMIC, institutional, and policy implications of these international arrangements and possibilities are examined.

CONTAINS papers presented at a conference held under the auspices of the University of Manitoba, Canada, Faculty of Agriculture and members of the Iowa State University Center for Agricultural and Economic Development.

A NORTH AMERICAN COMMON MARKET offers new and creative thinking on the problem of food surpluses for the few and hunger for the many.

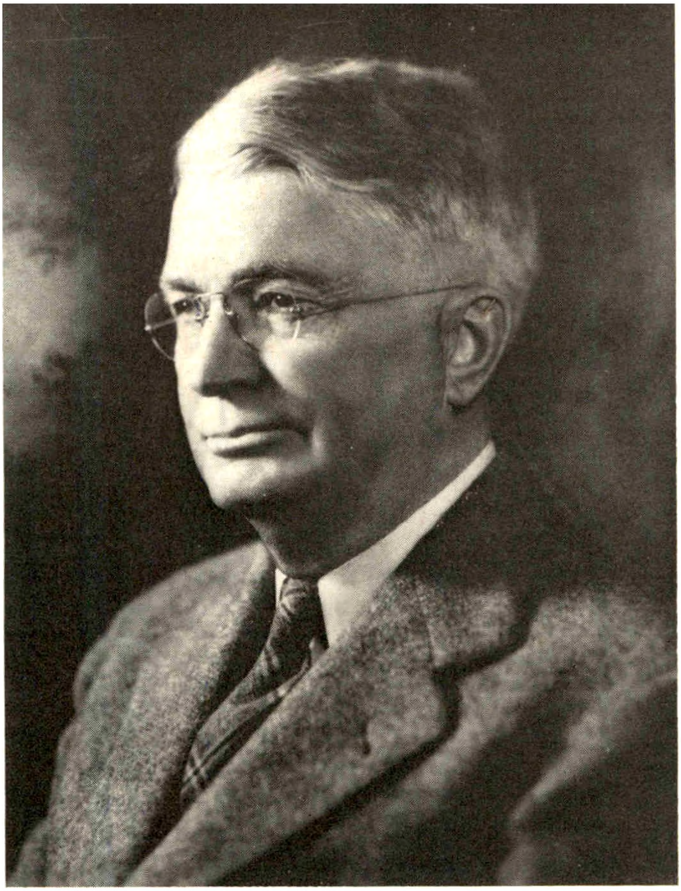
- The AMERICAN JOURNAL OF AGRICULTURAL ECONOMICS is issued five times a year, in February, May, August, November, and December. Prior to 1968, this JOURNAL was the JOURNAL OF FARM ECONOMICS.
- Published by the American Agricultural Economics Association.
- Printed by the George Banta Company, Inc., Menasha, Wisconsin, U.S.A.
- Second-class postage paid at Menasha, Wisconsin.



Henry Charles Taylor
1873–1969

HENRY CHARLES TAYLOR died April 28, 1969, at age 96 in Washington, D.C. His professional life spans the life of our profession. Our association honored him as one of the pioneers, first as its president in 1920 and more recently as one of the first to receive a fellowship [3].

H. C. Taylor was born and raised on an Iowa farm. He earned his B.S. and his M.S. degrees from Iowa State University. Before finishing his Ph.D. at Wisconsin in 1902, he studied at the London School of Economics, Halle-Wittenberg University, and the University of Berlin.

As a professor in the University of Wisconsin's Commerce Department, he taught a course in agricultural economics in 1903. He was listed as a professor of agricultural economics in the Wisconsin College of Agriculture in 1907; and when an agricultural economics department was formed in 1909, Professor Taylor became its first chairman [4, pp. 270–273].

Professor Taylor said, in the first B. H. Hibbard Memorial lecture, "Agricultural economics had its early growth as a part of general economics on the one hand, and as a part of agronomy on the other hand." He lists six pioneers: Warren, Spillman, and Boss, who entered the field from agronomy; Carver, Hibbard, and himself, who were all students of Richard T. Ely and brought general economic training to bear on the problems and policy issues of farmers [7].

Taylor's concept of agricultural economics was a broad and inclusive one. This was evident as early as 1910 when he persuaded Professor Galpin, a rural sociologist, to join the staff [4, pp. 270–273]. To Taylor, history and economic geography were also important in analyzing and resolving rural economic issues. He was an early user of the dot map to present information. Professor Taylor's Ph.D. thesis analyzed land ownership problems in England. The first Wisconsin Experiment Station bulletin on an agricultural economics subject, published in 1910, was *Methods of Renting Farm Lands in Wisconsin*, by H. C. Taylor [9].

Early in 1919, Professor Taylor became chief of the Office of Farm Management in the U.S. Department of Agriculture and, at the same time, was assigned to a commission whose purpose was to reorganize the Office [11, 13]. The commission's work resulted in the establishment of the Bureau of Agricultural Economics within USDA in July 1921, with Dr. Taylor its first chief [5, p. 152]. As chief of BAE, USDA, until 1925, Dr. Taylor had a large responsibility for, among other things, expanding the agricultural information services, inaugurating the Agricultural Outlook Service, establishing foreign outposts of USDA to get better information on world production and consumption, and putting the exports of American crops, particularly cotton, on American grading standards [8, p. 63; 1, p. 1100]. H. C. Taylor would want us to remember him as the one who organized and made function a large government bureau which did research and supplied information for better decisions on the broad program and policy issues of agriculture. In fact, his involvement in the controversial McNary-Haugen legislation might have had something to do with his retirement soon after the death of Secretary of Agriculture H. C. Wallace on October 25, 1924.

Before becoming the first managing director of the Farm Foundation in 1935, a post he held for ten years, Taylor was professor of agricultural economics at Northwestern University, directed a comprehensive study of rural Vermont, and was the U.S. member of the permanent committee of the International Institute of Agriculture, Rome, Italy.

During Taylor's administration, the Farm Foundation focused on the broad problems of rural communities and encouraged closer working relations between research specialists in the state colleges of agriculture and those in USDA [2, 10]. Under the sponsorship of the Farm Foundation Professor Taylor authored *The Story of Agricultural Economics*, published in 1952 [12, pp. 82–85].

A major contribution to our profession and one not often noted, is Taylor's effort to improve the working relationship of agricultural economists in the state colleges and in the U.S. Government agencies. The report of the Commission outlining the establishment of BAE contains an excellent statement on desirable research relationships between state and Federal specialists. While in charge of the Farm Foundation, he directed its main efforts toward encouraging coordination of the work of existing agencies and stimulating their staffs to initiate new lines of work.

Better documented and more widely known were Professor Taylor's continuous efforts to bring general economic theory and research methods to bear on the problems of agriculture. Recognizing the importance of making the individual farm efficient and profitable, Professor Taylor also included in agricultural economics those things important to agriculture that occurred beyond "the line fence"; hence, his interest in marketing, credit, prices, and ownership. He was a good teacher and his *Agricultural Economics* was the standard text for many years. He encouraged the American Economic Association in 1907 and 1908 to devote sessions to agricultural economics [6] . In 1910 at Ames, Iowa, a small group attending a graduate school seminar sponsored by the State Experimental Station Association formed the American Farm Management Association. Taylor disapproved of the name, and is credited with getting the Experiment Station Association to define farm management at its meeting in 1911 to include the general issues of the rural economy—marketing, credit, land tenure, rural living, and international trade. By 1919, definition of subject matter was not so important; and the American Farm Management Association, a marketing association, and a small fledgling association of agricultural economics merged to form our American Farm Economics Association. Whether the problems most affecting U.S. agriculture were credit and cooperatives in 1910-20, production control, adequate information, and international trade in 1920–30, or the problems of farmers losing their farms during the depression of the 30's, Henry C. Taylor was trying to apply research information toward improving the situation.

Taylor's interest in the profession continued until his death. Many of us knew him as an active member of our association and the International Association of Agricultural Economics. He also participated in the Washington chapter of the Taylor-Hibbard Club (members of this club bearing his name are students, staff, and alumni of the University of Wisconsin agricultural economics department, associated primarily to stimulate discussion of subject matter issues). At the time of his death he had prepared a manuscript on the economic history of the Iowa farm where he was born, which he felt illuminated the entire period of development of agriculture in the Midwest. It is in the process of publication.

NATHAN MORRIS KOFFSKY
Former Administrator of the Economic Research Service and Director of Agricultural Economics, U.S. Department of Agriculture
Vice-President of AFEA, 1959–60
Fellow, American Statistical Association

NATHAN M. KOFFSKY has made original and enduring contributions to general agricultural economics, national income estimation, agricultural-industrial relationships, and farm programs for underdeveloped countries.

His career in the U.S. Department of Agriculture extended from his temporary appointment to work on a BAE farm management survey in 1934 to his service as Administrator of the Economic Research Service, 1961–65, and as the Department's Director of Agricultural Economics in 1965–66. The high level of economic and statistical services achieved under his direction has enabled the Department to provide a broad perspective of American agriculture.

As a statistician, he pioneered the development of data showing the proportion of farmers receiving incomes of various sizes in relation to the value of their sales and was responsible for major advances in measuring the relative purchasing power of farm and nonfarm people. He also improved techniques for forecasting the effects of changes in aggregate domestic and foreign demand on farm prices and incomes and directed basic research in forecasting farmers' purchases from the industrial sector of the economy.

In the early sixties, he directed a comprehensive study of U. S. sugar policies for the House Committee on Agriculture and chaired a Department appraisal of the grain export policies of the Commodity Credit Corporation. He represented the United States at many international conferences, particularly those of the Food and Agriculture Organization and the Organization for Economic Cooperation and Development. He was especially influential in establishing a committee on the relation between agriculture and economic growth in the OECD countries, which completed an important study in 1965.

Nathan Koffsky's achievements were recognized by the USDA with a Superior Service Award in 1955 and a Distinguished Service Award in 1963. He served as vice-president of the American Farm Economics Association in 1959–60; was a member of the executive committee of the Conference on Research and Wealth of the National Bureau of Economic Research in 1953–55; and was elected a Fellow of the American Statistical Association in 1964.

As an economic program specialist with the Ford Foundation in India during 1966–67, he established an effective economic forecasting system for Indian agriculture. Subsequently, he has participated in several other research projects concerned with economic development in Asia and Latin America.

Nate was born in Albany, New York, in 1911. He received his B.A. from Cornell and his M.S. in economics from the American University in Washington, D.C.

JAMES GRAY MADDOX

Executive Director, Agricultural Policy Institute, North Carolina State University

Co-author, The Advancing South: Manpower Prospects and Problems, 1967

Formerly Bureau of Agricultural Economics, Farm Security Administration, American Universities Field Staff

JAMES G. MADDOX, through his perceptive writing and educational effort, has made major contributions in the fields of agricultural policy, economic growth of the southern region, and foreign development. He has devoted his life to bettering the economic conditions of rural people, particularly the rural poor. His interest has known no national boundary nor racial distinction.

James Maddox has always insisted that economics be applied to solving the problems society faces. His interest in agricultural policy goes back to his earliest years as an economist when he served as assistant to the chief of the Bureau of Agricultural Economics and as director of the Rural Rehabilitation Program of the Farm Security Administration in the 1930's. At North Carolina State University since 1958, Professor Maddox has been associated with the Agricultural Policy Institute in recent years and has served as its executive director since 1966. In this capacity he has organized conferences on a wide variety of topics related to the efficiency of the economy and the enhancement of incomes of rural people.

He served as research director for a four-year study, financed by the Twentieth Century Fund, concerned with development of the South. Out of this study a book, *The Advancing South: Manpower Prospects and Problems,* was published in 1967. In addition to this significant work, Dr. Maddox has written many papers and presented countless talks dealing with the problems of the South. Earlier in his career, Dr. Maddox was a Latin American specialist as a member of the American University's Field Staff from 1953 to 1958 and as an assistant director of the Rockefeller-financed American International Association from 1949 to 1952. In this period he produced a number of important papers and a book on Latin American institutions and problems.

His other contributions to the nation and to his academic and social community are immense. He has been a member of the Middle Atlantic Regional Manpower Commission and was a member of the Secretary of Agriculture's Public Advisory Committee on Rural Area Development from 1965 to 1968. He also has been a member of the Agricultural Committee of the National Planning Association.

A native of Arkansas, Dr. Maddox received his B.S.A. from the University of Arkansas in 1927, his M.S. from the University of Wisconsin in 1930, and his Ph.D. in economics from Harvard in 1950. In addition, he studied at the London School of Economics.

Walter William Wilcox
Legislative Reference Service, Library of Congress
Former Director of Agricultural Economics, U.S. Department of Agriculture
Former Assistant Chief of Division, War Food Administration

WALTER W. WILCOX, with his brilliant concepts and searching analyses, has had a stimulating as well as a moderating influence upon agricultural legislation and policy for two decades. His skill in adapting the technical, objective knowledge of the agricultural economist to the conflicting needs of the legislator and administrator has caused his advice to be sought at every level of government. His books and other writings have enlarged the views of a generation of students and scholars.

His outstanding competence in farm policy stems from a foundation of significant research. His first writings, reporting the results of research in farm management and production economics, reflected an awareness of the human factors in agriculture. This humanistic interest has given his work a vitality and reality transcending theory and its application. Much of his research in this area was distilled in his work on social responsibility and farm leadership.

His research in the field of agricultural prices, which again has contributed to theory and its application, has also clearly reflected his humanistic views. He has shown that agricultural prices are intimately related to types of production and farm holdings. He has then posed, in clear, unequivocal language, the alternatives open to America and their possible effects upon rural life.

More recently, he has emphasized the relation of nutrition, both on the national and the international scene, to production economics and to farm policy.

Born on an Iowa farm in 1904, he earned his B.S. degree at Iowa State, his M.S. at the University of Illinois, and his Ph.D. at Harvard. After beginning his professional career in the Bureau of Agricultural Economics, 1930–35, he served on the staff at Iowa State University, 1935–42, and then was with the War Food Administration. He taught at the University of Wisconsin, 1944–50, and from there went to the Legislative Reference Service of the Library of Congress. He was appointed Director of Agricultural Economics of the U.S. Department of Agriculture in 1967 and resigned from that post in 1969 to return to the Library of Congress.

In 1956, he undertook an assignment in Chile for the Food and Agriculture Organization. He has also undertaken short-term teaching and research assignments for several universities and organizations. For many years, through the USDA Graduate School, he has offered a seminar in agricultural policy for leaders in policy development and implementation. He edited the *Journal of Farm Economics* from 1949 to 1951.

DALE E. HATHAWAY is chairman of the Department of Agricultural Economics at Michigan State University, where he has been a faculty member since 1948. At Michigan State he has been engaged in teaching and research in agricultural price and income policy, labor mobility, rural poverty, and agricultural political processes. He has served as a senior staff member of the Council of Economic Advisors and as a visiting professor of economics at the University of Chicago. He has served as a consultant to the Commission on Food and Fiber, the National Advisory Commission for Rural Poverty, and the United States Department of Agriculture, the United States Department of Labor, and the Council of Economic Advisors. Dr. Hathaway is the author of two books, *Government and Agriculture* and *Problems of Progress in the Agricultural Economy,* and has published numerous research bulletins and journal articles. He won the AAEA award for best published research in 1956, 1958, and 1967. He was a member of the Editorial Council in 1958, 1959, and 1960 and was vice-president of the Association in 1962-63.

PRESIDENTIAL ADDRESS

The Economics of Agricultural Economics*

DALE E. HATHAWAY

As an economist addressing other economists, it seems natural to me to use our basic analytical tools as a framework for discussing future challenges to our profession. Thus, an evaluation of the supply and demand for the services of agricultural economists seems to me to be an interesting and useful intellectual enterprise. In a time of rapid change, the probability of failing to anticipate major market shifts and adjust to them seems great. For economists, such a failure would be inexcusable. The stories are legion about physicians too busy to notice their own health problems. It would be unfortunate if we were too preoccupied to apply a modest amount of economic analysis to the services we supply—just as we analyze such factors.

I am concerned today about the well-being of the profession; I am concerned because I believe that a relative decline in our position would reflect our failure to meet adequately the needs of the society we serve. This is not to imply that the market test of a profession's performance is the only valid one, but we cannot ignore such a test in an economy responsive to consumers of both public and private services.

My underlying assumption is that science–social or otherwise–exists to serve man and not vice versa. Thus, it is my belief that our success and ultimate rewards will be related to our ability, as a profession, to provide meaningful answers to mankind's important problems in the decades ahead.

The impetus for these thoughts initially came from two sources. The first was T. W. Schultz's stimulating Fellows lecture at the 1968 annual meeting [4]. His theme involved the application of traditional supply and demand analysis to institutions. My parallel regards the supply and demand for professional services, some of which are profoundly affected by our institutions and the changes or rigidities in them. It assumes, however, that such institutions are within our control and that our supply of services is thus largely self-determined.

The other stimulus leading to my discussion was the report of three

---

* I have benefited greatly from the comments of L. L. Boger, James T. Bonnen, Glenn L. Johnson, Lester Manderscheid, James D. Shaffer, and John A. Schnittker. Miss Kathleen Wilk provided the statistics underlying parts of the analysis.

DALE E. HATHAWAY *is professor of agricultural economics and chairman of the department at Michigan State University.*

studies of economists' income, inaugurated by the American Economics Association and published in December 1968 [6]. One study indicated, somewhat to my surprise, that economists' salaries were second only to mathematicians' (by a very narrow margin), taking into account factors such as age, type of employer, years of experience, etc. This is in sharp contrast to the agricultural sciences, with which we are often closely associated. The agricultural scientists have the lowest income of any of the professions, taking all factors into account, and are more than one-fourth below economists [5, p. 56, Table II-4]. Among economists, agricultural economists do not fare quite as well as monetary specialists, but the differences among the specialists in our discipline are modest (ten percent) relative to that between disciplines or between different employers of economists.[1]

All this suggests that we must be doing very well indeed for the public to have rewarded us so well as a profession. Even so, I judge the market to be shifting rapidly as a result of profound changes in our society, and I doubt that the services that were adequate in the past will meet the demands of the future.

In this respect it is important to differentiate between need and effective demand. The willingness to pay for professional services arises because it is demonstrated that the service can satisfy a need. Organ transplants in medicine are a case in point, for I suspect that the effective demand was completely absent until the medical profession proved it could provide a useful service. Now, apparently, the demand far exceeds the available supply of such services and the associated donors.

My general proposition can be stated simply: We have enjoyed an extraordinary demand for the services of agricultural economists in recent years. However, it is unlikely that the demand will be sustained for our present services. Thus, our future depends upon our willingness and ability to provide new and expanded services to meet the rising demands for services relevant to the major problems of our society. My belief is that certain internally imposed impediments stand in the way of our providing these services. The nature of the services demanded and some barriers to providing them constitute the bulk of my discussion.

It appears useful to reduce the aggregate concept of services to groups of relatively specific services: teaching, research, adult education, advisory and administrative services. Here we find substantial interdependence, for teaching affects the long-run supply of all the other services; current research services affect the subsequent services available in adult education and public and private policy making; and public and private policy making and administrative services affect the current and future demand for teaching and research services. Thus, we have not a simple set of independent supply and demand factors to look at, but instead, a large complex system that even elementary logic suggests requires analysis of a complex set of relationships. However, having said this, I shall proceed like most model builders to ignore most of the interdependence and attempt to discuss parts of the system as independent relationships.

---

[1] For instance, the mean net salary difference between teaching and management employment within economics was 22 percent and between B.S. and Ph.D. holders was 22.5 percent.

University Teaching—Undergraduate and Graduate

One ought to begin with the teaching services, for this and the associated processes of student selection, education, and placement are major determinants of the form and quality of services available to provide other services in subsequent years [3]. Some argue that our teaching services merely attempt to meet derived demands, but since few, if any, groups in society are more inner-directed than university faculties, I think this argument less than convincing. If there is truly an independent short-run supply function, it is in university education, for what is taught most generally is what professors perceive students to need, which often differs from the perceptions held by students and their future employers.

The demand for university level undergraduate instruction has grown fantastically in the past decade. For instance, the 1967 fall term enrollment in all undergraduate and first year professional programs in the United States was 240 percent of its 1955 level. Over the same period, the undergraduate enrollment in colleges of agriculture rose only 43 percent and that in agricultural economics by somewhat less.[2]

Even this casual examination of the statistics indicates that it is *not* the demand for undergraduate teaching services that has maintained the market for agricultural economists. While we have fared better in this regard than some of our colleagues in the agricultural sciences, we have not shared proportionately in rising university undergraduate enrollment—a factor that has been a major determinant of the demand in other branches of economics.

One trend in undergraduate programs is clear. In contrast to the situation reported by Nichols a decade ago, there has been a significant increase in both quantity and quality of undergraduate work in economic theory and quantitative techniques in recent years. In fact, many of our present undergraduates in agricultural economics possess a sophistication in these areas that was found generally only in the completing doctoral student of a quarter of a century earlier.

There are two reasons for this advance. One is the steady upgrading of the quality of secondary education of our undergraduates. The second is the increasing concentration in our curriculum upon social science and mathematics and the steady decline of technical agriculture. Prior to World War II and for a time thereafter an undergraduate degree in agricultural economics was often a thin veneer of social science over a large base of applied agriculture. Today, many undergraduate degrees in our field consist of large blocks of mathematics and social science held shakily into the form of an applied field by the thin mortar of a few technical agricultural courses.[3]

---

[2] The latter figure is based upon degrees granted, since the figures on undergraduate enrollment by major are questionable when available.

This marked change in undergraduate training appears to be a mixed blessing. On the one hand, it produces an input for graduate study in agricultural economics that more easily fits our standard graduate program. It also may provide a curriculum more appealing to urban-reared undergraduates, who often are both fearful and condescending toward courses in applied agriculture; but if the new curriculum is appealing to them, this attraction is not reflected in a tidal wave of enrollment.

The other side is that our increasingly specialized undergraduate programs may become less relevant to all but those preparing for graduate work in ours or a closely related field. The absence of either technical agricultural or humanizing courses may lead both to a less appealing undergraduate curriculum for the student planning to end his education at the bachelor's level and to entering graduate students who are better prepared to use the tools of the trade but with little idea of the important problems or the contributions that our analytical tools can offer to their solution. Thus, the lagging demand for our undergraduate programs may arise from our failure to recognize that our undergraduate training in the sciences, including social sciences, is designed primarily to professionalize and not to humanize. I believe that both can be done in an undergraduate program and that we would then have a superior product for both graduate study and the employment market.

There is one area of undergraduate training where we have clearly failed to meet the needs of society. At a time when the demand is for more attention to university recruiting and training for low income and minority groups, agricultural economics still draws its students largely from white middleclass families, especially those looking for a way out of rural employment. As economists, we have advised everyone else to look at resource allocation, and as policy advisors we have long decried the inadequate resources allocated to educating the disadvantaged in our society. Therefore, it is somewhat ironic that so few of the resources that we control have been allocated to recruit and train young people from disadvantaged groups. At one time colleges of agriculture, including agricultural economics, were important avenues of upward social and economic mobility for rural young people, although this was never true for minority groups. I believe it is imperative that we move rapidly to meet these demands with new resources and new concepts, much as we have done in training foreign students.

---

[3] For instance, a survey of the 1969 Michigan State University faculty in agricultural economics shows that those with their B.S. prior to 1950 had the largest block of hours in technical agriculture, with 24 percent as many in mathematics and statistics and 70 percent as many in social science as in agriculture. Conversely, domestic graduate students applying to Michigan State University in 1969 had more than twice as many hours in social science as in technical agriculture and two-thirds as many hours in mathematics and statistics.

It would be unreasonable to expect that we can or should have a greater demand for our undergraduate teaching services from any group unless the services provided are of value to the recipients. They will not be of value unless we recognize that our society is no longer predominately rural and that our food and fiber industry is no longer predominately on the farm. C. E. Bishop covered this point most thoughtfully in his presidential address [1]. We still are not adjusting our undergraduate teaching services sufficiently to recognize it.

Graduate Training

In contrast to undergraduate programs, where degrees granted in agricultural economics have risen less than a third in the past decade, the demand for graduate training in agricultural economics has risen rapidly, with enrollments up more than two-thirds in a decade.

Even this is misleading, however, for the master's degrees granted annually in agricultural econmics have risen less than 20 percent over the past decade, whereas doctorates have almost doubled. One has to ask, then, why has the demand by students for doctoral training in agricultural economics been increasing so much more rapidly than for lower degrees?

Part of it can be explained as a straightforward response of students to the return on the additional investment. A B.S. in agricultural economics probably has less market value than a B.S. in many other sub-fields of economics. In the United States, at least, the value of the master's degree is only a little above the bachelor's degree in economics while the Ph.D. offers high returns to the individual, especially if its cost is kept low to the individual by fellowships and research assistantships.[4] But I believe that the demand for advanced training goes beyond monetary motivation to the belief that we are training persons to offer *useful* social services.

The rising demand for graduate work in agricultural economics appears to have three roots: (1) the demand for graduate training for foreign students; (2) the demand created by persons headed for a university or government research career, especially in the field of international development; and (3) the demand by those preparing for a career in the business world. Beyond these is the continued public and private demand for people from government and universities for administrative and policy making roles in both the public and private sectors.

---

[4] The American Economics Association survey indicates that the master's in economics adds only six percent to net salary over a bachelor's degree.

Much has already been written about the suitability and quality of our graduate training for foreign students. I shall not engage in that discussion here but wish to point out a possible long-run demand shift for graduate training of foreign students. If we are at all successful in our institution-building projects abroad, the current level of demand for training foreign graduate students is not likely to be sustained. It appears probable and desirable that many of the master's students, and eventually a major portion of the doctorates in agricultural economics will be produced in foreign national or regional universities. We should remember that 50 years ago it was fashionable and desirable for Americans to get their graduate training in economics in British and continental universities, whereas such training now is relatively rare, presumably because the quality of our own training has improved. Moreover, as the relative gap between professional salaries in foreign countries and the United States closes, the value of a United States degree as an entry to our professional labor market will diminish.

A second expansion factor has been the graduate training necessary to upgrade the university and government staffs in agricultural economics and to fill the demands for foreign development assistance programs. The former passed its peak by the mid-1950's; it is possible that the latter has also peaked, as trained foreign students become available to meet the demands for agricultural economists in their own countries.

There is inherent in this an accelerator principle: We expanded staff to expand training of graduate students, which in turn created the demand for more graduate work, and so on. If that is the case, there also is the potential accelerator effect of a decline in one or more of these sources of demand and the possibility of serious overcapacity in graduate training facilities in the United States. This possibility is enhanced by the continued entrance of new institutions, with exit so rare as to be almost nonexistent. Since the unit cost of graduate training falls sharply as numbers in a single program increase, we may well face a problem of high cost programs (relative to other fields in economics), which may be especially troublesome in some institutions.

Prior to World War II, the major suppliers of Ph.D.'s in agricultural economics were a few—but a very few—land-grant universities and three or four well-known private universities. The situation now is very different. The largest producers of Ph.D.'s in agricultural economics are now the land-grant universities, and production is widely distributed among them. The major private institutions have declined both in absolute and relative terms.

The strengthening of graduate training in theory and quantitative methods seems almost universal; without it the shift in location might not have occurred. Emphasis on economic theory, quantitative methods, and analytical tools is widespread, whereas it was previously the hallmark of only a few institutions. This change is evident if one only looks at minimum Ph.D. requirements in most institutions; and, unpleasant as it may be to those of us trained in an earlier period, I believe it accounts in part for the steady narrowing of price differentials between new Ph.D.'s and those trained more than a decade ago who now may be suffering from technological obsolescence.

I would not want to end this discussion of graduate programs on a pessimistic note, for there are areas in which the demand for graduate work is expanding. One of these is the great need and potential demand for graduate training for persons from disadvantaged groups in the United States. We have too long used excuses about inadequate undergraduate background, weakness in verbal skills, etc., implying that the supply of potential candidates was lacking. If we had adopted the same attitude toward training foreign graduate students, those programs would have failed completely. If we will put as much effort into selection, preparation, and retention of students from our own minority groups as we do in the typical Asian or Latin American graduate student, we can attract and train much larger numbers from our minority groups without reducing degree requirements.

The greatest potential demand for graduate work in agricultural economics will be generated by the demand rising from new balance in our social science research and advisory programs. Webster (3rd. ed., unabridged) defines social science as "concerned with the welfare of human beings of society." During the last quarter of a century we have made tremendous strides in putting the *science* in our social science. Having done this, I believe we should now put additional emphasis on the *social* in our social science. Do not misunderstand me. I am not advocating a return to the prewar graduate programs lacking in adequate economic theory, mathematics, and statistics. But, just as there is no "welfare" in welfare economics, many of our present activities have little "social" in their orientation. Among other things, the younger generation is saying that our society should insist that science is used to achieve social goals, and I tend to agree. Unless we emphasize this in our graduate training and in our research and advisory work, we may find our graduates unable to meet the demands of society. Eventually, our graduate programs will fail to attract the best young people, and we will face a situation most difficult to reverse.

Research Services

In general, the demand for research services from agricultural economists has grown rapidly over the past quarter of a century and so has the supply offered. The supply has been greatly enhanced by the marked advance in training and equipment. Yet, as one views the problems of the world, there appear to be large areas of demand for research that are met inadequately and that should receive our attention if we are to contribute at a level anywhere near our potential. Let me spell out some of these demands and the changes needed to meet them.

The demand for research on aggregate policy questions

Increasingly, in response to requests of policy makers, our profession has applied quantitative research techniques to provide estimates of outcomes of alternative policy actions. This work has had a major impact on policy and has brought demands for more policy research. Of course, such research has not escaped criticism, especially when its results have been sharply at variance with the firmly held opinions of major political forces. Nevertheless, the demand for more and better policy research continues, but our policy research and its results are not adequate to meet the need.

So far our research has not dealt adequately with many of the major policy issues of deep concern to farm people and the larger society. We have offered little in research results on these issues: who should control the food and fiber industry; what are the total social costs and returns from different methods of organizing the industry or its subsectors; who does and should get the benefits from our expensive government programs; what is the most desirable distribution of our economic growth and population; how can we achieve a desirable physical environment in which to live and work; what trade policies will meet the multiple goals we have with respect to the rest of the world. Moreover, as Bishop pointed out, our policy models are still largely restricted to agriculture, with too little attention to inter-sector relations and to issues beyond economics.

Research on agricultural systems

Many observers, including my colleague, James D. Shaffer, have commented on the increasing interdependence and closer linkages between the various segments of the food and fiber industry. It is no longer correct to assume that the various sectors of the industry are interconnected by a series of perfectly competitive markets. And, once this assumption is dropped, it is no longer sufficient to do research on input producers, farms, marketing firms, and retail outlets as independent units. What is needed, and is increasingly being demanded for both public and private policy making, is an analysis of food and fiber systems. Business has known this for some time, and there is increasing recognition from farm leaders and policy makers concerned with the problems related to the industry's structure and performance, bargaining, and resource ownership and control.

Research on new institutions

James Bonnen has described the decline of the agricultural establishment in his prize-winning journal article [2]. In essence, he says that the old agricultural institutions, judged by their behavior, are no longer functional to meet the needs of present-day society. James Shaffer's recent paper expands and explores different aspects of this theme [5]. Our campuses—and indeed our society—are being torn apart by issues of the inflexibility of old institutions and attempts to build new ones that will function more effectively.

If one talks with rural people or their leaders, we find that they are acutely conscious that their local institutions—churches, schools, local government, cooperatives, farm organizations, etc.—are unable to deal with today's problems. While their immediate attention often focuses on the institutional barriers to solving their local problems, it should be noted that even at the national and international level, the pressing problems they see are the need for different international trade arrangements, greater farmer bargaining power, improved status of farm labor and the other rural poor, and new ways to revitalize the economic and social structure of rural America. Each of these involves major institutional innovation.

The demand for research and information on such subjects appears to be very great, yet little supply seems to be forthcoming. In some ways this is surprising, for an entire generation of great names in agricultural economics achieved recognition because they made contributions to solving problems by building new institutions. One only has to think of institutions like the Farm Credit Administration, the Farm Security Administration, the AAA, the BAE, price support programs, and land use planning to bring to mind literally scores of agricultural economists who played a prominent role in the design of these institutions, both from within and from outside. Frankly, I see too few people of equal ability and imagination concerned with such issues now. Conversely, as Schulz suggested, work on institutions without regard to the problems that the institutions must resolve is likely to prove unproductive.

Applied development research

There is, I think, a substantial demand both here and abroad for significant problem-solving research on development problems of poor countries. This demand is not being met adequately, but do not take this as an assertion that our profession has not made significant contributions abroad in a variety of roles. I am merely saying that our research contribution has not matched our resource capability.

Rarely do we find research that is addressed to the broader problems of a developing country, involving the allocation of very scarce resources and the results in terms of growth rates, income distribution, political implication, and the time path that is so important in countries tottering on the brink of economic or political disaster. As in domestic research, too little attention is given to the interaction between the rural and urban sectors.

Some characteristics of unfilled research demands

The research needs I have cataloged, only partial at best, reflect a pattern that must be recognized if we are to fill these demands.

First, most of this research is problem solving and requires going far beyond our common analytical models and tools. Almost always it involves dealing with complex value problems and political issues, and a Pareto-better solution is unlikely to be found. This leaves us frustrated as theoreticians, inasmuch as there often is no common denominator to deal with, and thus we cannot maximize over various alternative actions. Moreover, in most cases the decision rules (institutions) are not even agreed upon or known, so that the issues we usually assume fixed are among the most important variables to be dealt with.

Second, these problems are multidisciplinary (almost by definition), with the economic variables subject to change as a result of shifts in other variables.

Third, these problems generally involve many aspects of society, not just the sector we delineate as rural or farm.

Fourth, because of their scale and complexity, these problems generally require a large-scale critical mass of research effort in order to achieve meaningful results.

Barriers to providing the needed research services

As I see it, three major barriers prevent our offering the needed research services: (1) our increasing tendency to associate a single philosophical method (positivism) with scientific endeavor in the social sciences, (2) our inadequate administrative and institutional arrangements in research establishments, and (3) our long cherished belief in professional independence. Let us look briefly at each.

Our continued drive for better economic theory and for improved quantification has led us increasingly to the position that science does not deal with normative issues. This, of course, precludes dealing with values, non Pareto-better solutions, or matters lacking a common denominator.

We have few political economists any more, either in training or practice, and there tends to be a subjective professional downgrading of those willing to act as such. This issue has, of course, been widely, though sometimes obscurely, debated in our profession from time to time. My position is that we should not adopt research methodology that is too restrictive to allow us to meet the major demands for social science research. I would argue that being useful and relevant is more important than respectability, especially if the respectability is defined by an artificial set of rules promulgated to justify how the majority of the profession has decided it wants to act.

Our institutional and administrative research arrangements are almost entirely discipline oriented and, moreover, oriented to relatively small units of professional input. Thus, we lack the organization necessary to do either multidisciplinary or multiunit research. If the needed research is to be done well, most of it must be multidisciplinary, involving technical as well as economic relations and other social sciences. Our traditional organizations have not been very successful in developing such research teams.

Efforts to use regional research mechanisms to overcome this problem thus far have not been notable for their success. The interregional research mechanism has fared little better. Moreover, with few exceptions, the regional projects have been disciplinary in focus rather than multidisciplinary. One reason for the rapid growth of private research organizations appears to be their superior ability to put together research teams appropriate to tackle these kinds of problems.

Our research on foreign development problems has been especially handicapped by our inability to develop a viable overseas research mechanism based on United States funds and manpower. As yet, no institutional arrangement has been developed that will provide the long-term funding, overseas base, and professional rewards comparable to our domestic research programs. Overseas research problems have been compounded recently by a rising political aversion in the United States to foreign aid, in which research tends to be lumped with other forms of assistance. We have seen indications that the new directions in US/AID may solve this problem in part, but it will take far more than substantial block grants to solve the many problems involved.

The third barrier to our effective supply of needed research services is largely derived from our internal professional image. Since our profession developed during a period of laissez-faire, it is perhaps only to be expected that our research organization consists primarily of a large number of individual entrepreneurs (often on public payrolls). We now are primarily a collection of individuals, producing small bits of analysis that we hope will be demanded in the marketplace of ideas. The research system is typified by small individual projects, an individual reward and promotion system, and by the American Agricultural Economic Association's system of recognition of *individual* research and journal articles. It has been fortified by (or has produced) a professional view of "every man a king" or "all chiefs and no Indians" in that research teams are viewed with suspicion, if not with alarm, by everyone from the new Ph.D. to the most senior professor. If the auto manufacturers followed the same principle, several companies would ship the buyer a variety of car parts, which might or might not fit together to be assembled without instructions. There are some who would assert that this might produce a product superior to that now available, but this approach assumes tools and skills not generally possessed by consumers of either cars or research; and it ignores the concepts of complementarity and scale that are so popular with economists when applied to the activities of others.

These impediments are self-imposed by our training, our professional views, and our self-made institutions, and therefore should be entirely within our power to change. Certainly they present far fewer difficulties than the well-entrenched outside political institutions. The question is whether we clearly see the need for change.

Adult Education and Advisory Service

Historically, the demand for advisory services on organization and management problems of individual farms and marketing firms has been a major source of demand for services of agricultural economists and the cornerstone of public support for our teaching and research programs. To some extent, these services have escaped some of the issues that have inhibited our research work on other problems, partially because some of the issues are absent. Such work has been multidisciplinary, for most workers in the area recognized that these problems were broader than economics. Moreover, we have either used the goals defined by the demanders of the service or helped them develop new goals, often ignoring the conflicts between these goals and those of society at large. And, until recently, the firms involved have been sufficiently small that individuals or small teams could adequately handle their problems. But in this area, as much as in any other, the major structural shifts in the food and fiber industry are leading to demand shifts with possible long-run implications.

What are the demand implications for our farm management and marketing programs of the steady drift toward an industrialized food and fiber industry with large-scale production units, often owned or tied to large nonfarm industries by contact and other devices? What are the demand implications for our services of the prospect of organized farm labor, commodity-wide producer bargaining, and full-supply contracts for inputs? These shifts will create most of the conditions that have hampered our effectiveness in problem-solving research, for advisors will then have to deal with value conflicts, scale problems, and greater interdependence with other segments of society.

How will we meet these new demands? I have no answers to these difficult questions, but I believe that serious analysis is overdue. We have for years told producer and marketing institutions to reorganize and to adjust to change in demand if they expect to survive, yet we seem to be doing little of the basic thinking necessary for us to reorganize our own supply of services.

In the area of domestic work with the rural poor and community development, as well as price, income, and trade policy, we have been less than completely successful. This is not altogether surprising, since advisory work in these areas has the same characteristics as research work and suffers from many of the same impediments in philosophy, organization, and intellectual independence. Moreover, work in these areas has been impeded by our concern with the political power of the traditional agricultural establishment and its belief that such work is competitive with the interests of the commercial food and fiber sector.

In the quarter century since World War II, a major expansion has occurred in the demand for education and advisory work in developing countries, manifested largely through American foundations and United States government agencies. Initially, the demand was heavy for persons who could deal with micro problems, especially relating to farm production. As on the domestic scene, those involved have avoided some of the pitfalls mentioned earlier and have worked on problems as they arose, but this work has suffered substantially from inadequate administrative-institutional arrangements.

The supply of services offered to meet this demand has been uneven in quality. Perhaps most important, however, has been the short-term basis of the services. The reasons for this have been several: (1) The majority of United States institutions have regarded foreign work as auxiliary at best, and more often as competitive to their ongoing domestic programs. (2) Many of the individuals concerned have felt (probably rightly) that their professional prospects were brighter if they combined foreign and domestic work instead of becoming career persons in overseas work. (3) The overseas worker has been forced to operate without the necessary research base.

Problems on the supply side have been related directly to uncertainties created by the demand. As yet, no successful administrative model has been developed to provide the demand stability sufficient to induce major institutions to supply the total package of services needed. Thus far, the most stable element of this demand has been the direct hire program of the foundations and government, but this often lacks the research ties and the intellectual interaction that might be provided by the universities, the Economic Research Service, and private business.

At the present time there is a fundamental shift under way in the level and nature of the demand for overseas advisory services. For a variety of reasons, the level of demand from both the United States government and the foundations has declined recently, and its future level from each is uncertain. And the nature of demand is shifting toward a new type of advisory service with the somewhat belated recognition that significant problems of macro-policy nature may be crucial in determing micro-firm actions. This demand is being accentuated by the increase of "second generation" problems engendered by some technical breakthroughs in production. Increasingly, these will involve matters of scale, interdependence, and extraordinarily difficult value questions and political issues.

It appears that both government and foundations are recognizing these problems and that some stabilization and expansion of this demand may be expected in the years immediately ahead. If so, it will then be up to us, as individuals and as participants in institutions, to prove that we can provide the necessary services.

I am hopeful that the instability on both the demand and supply sides will subside rapidly and that a new set of relationships can be established. It is inconceivable that those hoping to build new institutions around the world cannot develop adequate institutional arrangements at home to do the job.

Administrative and Policy-Making Services

The demand for services of agricultural economists has expanded most rapidly at the administrative and policy-making levels in universities, business, government, and international agencies. At the upper levels in the Department of Agriculture, economists are replacing professional politicians and farmer-leaders. A large number of land-grant university presidents and vice-presidents come from our ranks, and the proportion of Deans of Agriculture from our ranks is as pleasing to us as it is irritating to our colleagues in other agricultural fields. We find our colleagues in business doing very well and the demand for agricultural economists in business seems to be still increasing. Indeed, without this heavy demand for administrative and policy-making services by agricultural economists, the market might be very depressed, given the relentless, self-powered supply of new entrants to the field. The questions then are: What created this demand? Will it continue to expand?

A major factor in the continued demand for agricultural economists in administrative roles is the generally outstanding performance that our profession has exhibited in them. Even though our research and teaching emphasis has become increasingly discipline oriented, agricultural economists in administrative and policy-making roles continue to be problem oriented and recognize that many factors outside economics need to be considered.

If my analysis regarding trends in our training is correct, it raises an interesting question for the future supply of such services. Are we, in our drive for more intensive disciplinary training in economics and mathematics, in danger of so narrowing the focus of our graduates as to reduce substantially the likelihood of their making future contributions in policy-making administrative roles? And has our scientific image become so important to us that we are no longer willing to participate in public service at some possible sacrifice to our "scientific" careers? These are, I think, especially crucial questions in our training of foreign students, who because of their training, are likely to have opportunities for important administrative positions, often soon after completing their graduate work.

Conclusions

Based on the market test usually applied in our economy, agricultural economics is doing well. The returns for our services are high relative to most other professions, especially so relative to our colleagues in the agricultural sciences. My contention, however, is that this should give us little reason for complacency because much of our current well being may be due to demand factors that will not continue.

Since World War II, we have made substantial improvements in both our theory and methodology. These have been reflected in shifts in our undergraduate and graduate training and in our research and advisory programs. The ground work is well laid for either continued advances and contributions or for a retreat to a narrow focus that will limit our contributions to society.

To accomplish the things that will be demanded will require major institutional and professional adjustments on our part. We must examine critically our philosophy of science, our administrative structures, our systems of small individual research projects, and the future utility of our almost complete intellectual independence. We also must examine carefully our political support and related financial base, which is increasingly tied to commercial agriculture, and, moreover, to a rapidly disappearing segment of that. I am not suggesting that we abandon our service to commercial food and fiber producers, but that we broaden our services and our political and economic support far beyond them.

Twice in my more than two decades in this profession, I have seen the farmers in this country lulled into the belief that the market demand for their products was unlimited and growing, only to be rudely shocked back to reality by shifts that were in line with the long-run world supply and demand for food and fiber. Even though the civil service and university tenure provide a comfortable price support and storage program for agricultural economists, I would hate to see our profession compelled to fall back on these because we have failed to anticipate and adjust to shifts in demand.

Ultimately, our success as a profession will rest on how we define our potential role in society and on the services we are willing to provide society under this definition. To have continued success, I believe we must combine two basic elements—an even greater excellence in our training and practice as economists and a willingness to apply our economic tools in our teaching, research, and advisory work as parts of new groups in organization and scope, with sufficient scale to help solve the significant problems of society.

I am optimistic, for I believe that in this context the potential real demand for our services is very high; and if we adjust our services to meet the demands, we should prosper. If in one or two decades we find ourselves in a relatively less favorable position than now, it almost certainly will be due to our intellectual and institutional rigidities, not to society's lack of need for our services.

A Future for "Agricultural Economics"?

James M. Buchanan

I shall preface my remarks with a relevant and deserved tribute to the late Professor Wilson Gee of the University of Virginia. Gee was a prophet without honor in his own university, and it is fitting that I pay him tribute here among some men who may have known him. Gee came to Virginia early in the 1920's and, after a dispute with other economists, he split off and established his own department which he called "Rural Social Economics." Almost single-handedly he developed a Ph.D. program which awarded some 20 degrees over a thirty-year span, some of whose recipients remain leading educators and public officials today. Apart from all this and complementary to it, Gee secured external funds, established an institute, published twenty-seven books through its auspices, and forced the state legislature in Virginia to include an annual appropriation for social science research. The latter remains a mighty achievement today; you can imagine the odds against Gee in the 1930's.

My reference here to Wilson Gee is not opportunistic or passing. I shall argue that one future for "agricultural economics," as a scholarly subdiscipline worthy of continuing public and private support, and especially in land-grant universities, is provided in the approach that the title of Gee's now-defunct department suggests, "Rural Social Economics."

Before getting into my central argument, however, let me clear the air by stating briefly my own views about disciplinary and subdisciplinary classifications. I have never considered these to be of much import, and one of my personal criteria for evaluating an administrative unit is its willingness to discard and forget about "fields" and "areas." I have never been impressed by the departmental chairman or recruiting officer who says that we must fill a vacancy in "labor," in "trade," etc. The various subdisciplines in economics seem to me more or less arbitrary, in any case, and dependent more on accidents in academic history than on anything else. Good economic theory can be taught, and students can be trained to apply it, under a host of rubrics, including many not yet dreamt of in our educational philosophies. Hence, I do not mind very much when new courses are proposed in areas that attract current topical interest, provided only that the economics is rigorous and that the instructor is competently and professionally trained, in attitude as well as in technique. I see no cause for alarm when proposals are made for courses and specializations in such things as "economics of poverty," "ghetto economics," or

---

James M. Buchanan *is professor of economics and general director of the Center for Studies in Public Choice at Virginia Polytechnic Institute.*

"defense economics," "economics of development," or "urban economics."

Having stated a general position, let me hasten to add that I recognize, to the extent possible for an outsider, the special characteristics of "agricultural economics" that make the problem of preserving its importance as an independent subdiscipline more significant than many of the other fields or areas. Within a single organizational unit, normally a department, fields or areas of instructional and research specialization may be added, dropped, transformed, although admittedly sometimes with great difficulties and with long lags between desire, decision, and action. "Agricultural economics" is, however, different precisely because in most universities, it is organized independently as a self-contained departmental unit, often located in a wholly different school or college from that which houses the more inclusive discipline of economics. What is the future for "agricultural economics"?—this questioning form of my title takes on more substantive content when this peculiar institutional independence is acknowledged.

I want to make one further point by way of introduction. I shall presume that there does exist doubt and fear, at least on the part of some, concerning the long-term viability of the subdiscipline's status. Implicit in the willingness to raise the question about the future must be the hope that, with proper foresight and planning, followed by responsible action, the long-term prospect need not be the gradual decline-demise that straightforward projections embody. On this score, my paper can, I think, be taken to be optimistic. Properly transformed, the subdiscipline can reestablish itself as a vital center for instruction, research, and scholarship with an emphasis on orientation that is currently largely ignored and overlooked. It is this new emphasis that explains my initial reference to Wilson Gee. I want to suggest that a future for "agricultural economics" lies in its transformation into something that might appropriately be called "rural social economics," or simply "rural economics," or, if you do not like this, "non-urban economics." This can be an area of fascinating scholarship in the decades ahead, and major contributions are waiting to be made. The transformation can be accomplished without great difficulty, although of course after some time lags. The transformation would be, I assert, not only in your own interest as professionals in a subdiscipline but also in the interest of us all as citizens of the America of the 1970's. To justify this assertion, I must first digress briefly into the sometime murky regions of methodology.

What Should Economists Do?

Since I have elaborated my position elsewhere [1, 2], I apologize to those who must be subjected to repetition here. Baldly stated, my position is that economics as a social science is more than applied mathematics.

Far too many currently practicing professionals in economics, both in the parent discipline and its various applied fields, act as if there is nothing more than applied mathematics in it after all. Commencing with Robbins' definition of the "economic problem," they spend all of their energies working on variations of simple maximization and minimization, on allocation and efficiency, whether this be at the level of the individual choosing agent, the consumer, the producer, or the firm, or at the level of the community-collectivity acting through political-government processes. The procedure is all too familiar· Once an objective function is specified, the constraints are introduced, and away we go with the simplistic manipulation of everyday mathematics. Advances are hailed when we "solve" more complex problems, which are introduced by making our constraints mathematically more intricate and more complicated. All of this would be bad enough if we stayed at the level of the single utility-maximizing consumer or the single profit-maximizing firm. It becomes near-ludicrous when the same procedure is extended to "public choice," to the economic problem that is presumably faced by the whole community. Here economists often adopt a ridiculously arrogant position by hypothesizing implicitly that they are appointed as all-powerful despots. Once this step is taken, the routine is carried on as before. Objective or target functions are specified, constraints are defined, and on we go with solving all of our "social ills." Is it any wonder that economists remain shocked and bewildered when ordinary politicians, who necessarily respond to public demands, refuse to accept their proffered solutions?

I should emphasize that I am not questioning the efficiency of applied mathematics, or indeed that of engineering in any of its forms. The role of the engineer is an honorable one, and without engineers, where would our theorists be? But I do object, and strongly, to the confusion between economists and engineers. By a coupling that has had some tragic educational implications, economics is often institutionally paired with business administration which, properly handled, can be a legitimate area of engineering. Many economists would, of course, join me in these strictures against the association of economics with the maximizing skills of business firms. But, unfortunately, many of these same economists then will happily devote most of their own energies to telling us all how governmental or public policy "should" be arranged. On this I want to be clear; "social engineering" is no more a part of economics than is "business engineering" or "agricultural engineering." To the extent that "agricultural economics" is, in reality, engineering aimed at helping agricultural firms make greater profits or helping these firms to produce more efficiently, it belongs more appropriately in business administration than anywhere else. This has been properly recognized by many of the business schools, as witness the recent growth in courses of instruction in "agribusiness."

Economists, as professional social scientists, should possess a comparative advantage, not in applied mathematics, but in their expertise in a particular sort of human behavior and in the institutions that emerge from that behavior. Their task commences with Adam Smith's much neglected phrase "man's propensity to truck and barter." Men recognize that they can improve their lot by trading, and it is the economist's job to specialize in this. The institutional embodiment becomes the market, and it is the theory of markets that should be emphasized, not the theory of resource allocation. The economist remains within his professional limits when he analyzes the interaction processes through which prices are set and trades in goods and services implemented. He need not stop with organized markets. The economist is uniquely equipped to go beyond these confines and to explore man's never-ending quest for more complex and elaborate forms of voluntary cooperation. He should certainly examine the origins, emergence, and stability of institutions of all kinds, including the political. This basic methodological position justifies, of course, my own interest in collective decision making and in institutional analysis more broadly conceived.

The Economics of Agriculture

I stated earlier that the subdisciplinary classifications that exist are largely arbitrary and that good economics could be covered under many rubrics. Nonetheless, given the basic methodological position that I have outlined, we can identify some plausible schemes of classification among specialized areas of research and instruction The appropriate criteria for classification are recognizable differences in the institutional-technological constraints within which individuals behave. As an obvious example, the interaction of men in a fully competitive private-goods market process is different from the interaction of these same men in a collective-decision, public-goods, process. Technological differences in the interpersonal divisibilities of goods and services may, in part, determine the institutional patterns, but the usefulness of some subdisciplinary dividing line between the private economy and the public economy seems clear. Further subclassification within each of these two broad categories can be made, and intersecting categories can be established similarly. As a second example, men who participate in the collective sale of their own skills through the agency of labor unions behave under quite a different set of constraints from those who sell their skills independently to buyers. Hence, labor economics, as a subdisciplinary specialization has claim to legitimacy although its potentialities for scholarship do not seem to me to have ever been properly exploited. We could go further and look at the different institutional structures implied by other subdisciplinary specializations, but these need not be discussed in any detail here.

Under the general criteria of classification proposed, is an independent "economics of agriculture" legitimate? Are the institutional-technological constraints sufficiently unique in agriculture to warrant the specialization that we have observed? There is no need for serious argument on this point. The agricultural setting does generate interesting and unique economic relationships. Only a partial summary of some of its features need be listed such as : (1) the homogeneity of final products, (2) the dependence of output on natural phenomena such as weather, (3) the spatial fixity of land, (4) the exhaustibility of the land input, (5) the perishability of final product, (6) the multiplicity of producing units, (7) the pervasiveness of governmental controls, (8) the peculiarities in leasing-rental arrangements. All of these, and many more features that are no doubt more familiar to you than to me, make for particular problems in the agricultural sector, problems that surely deserve specialist consideration and treatment. (On precisely similar grounds, of course, we can justify such areas as the "economics of fisheries," the "economics of the social services," the "economics of insurance" and many many others.)

By saying that an "economics of agriculture" has a plausibly defensible existence of its own, however, I am not saying that this is where the future of "agricultural economics" and "agricultural economists" lie. As they are now organized, the latter reflect major social investments in independent research, education, and scholarship. The opportunity cost of concentrating future efforts exclusively on the "economics of agriculture" seems excessively high. This is partially because as a field of study the economics of this one industry must decline in significance as the industry itself declines. Along this route lies relative stagnation for the whole field. I think that much more inviting opportunities exist for transforming this independent discipline into something larger, while retaining the "economics of agriculture" on its own terms as an integral part of the more inclusive field. What I am proposing is that those organizational units now calling themselves "agricultural economics" become more inclusive concentrations in "rural economics," within which the economics of agriculture will remain only a subsidiary part.

Urban and Non-Urban Economics

A somewhat different way of putting this is to suggest that the agricultural economists take a leaf from the urban economist's handbook. And it will be helpful to consider briefly this rapidly developing and currently popular area or field. Can we justify the independent place for "urban economics" as a subdiscipline, in some universities even as separate department or schools? In a sense somewhat different from that applied to the earlier treatment of the economics of agriculture, I think that we can do so. With "urban economics" we are not concerned with the institutional-technological constraints imposed on behavior by the characteristic features of a single producing industry or even by a group of industries. Instead, the presumption is that the very fact of urbanization, the concentration of people in space, itself modifies the economic constraints on behavior in such a manner as to warrant specialized consideration. Commencing from the fact of urbanization, the specializist organizes his curriculum and his research by drawing on many separate and complementary subtheories in economics. His becomes a synthetic expertise, with many subtheories combined in the application to urban affairs and problems. The specialist calls on: (1) location theory, (2) land economics, (3) tax theory, (4) public goods theory, (5) theories of external economies and diseconomies, (6) theoretical welfare economics, (7) collective-decision theory, (8) transportation economics (9) public-utility economics, and perhaps several other subspecialties. If he is a teacher, his product is a student trained in basic economics, and familiar with applying this economics to the peculiar institutional setting that the urban community represents. The student is trained in what we may call an "economic understanding" of the urban community. If he is a research scholar, his product is the illumination or explanation of particular aspects of urban community achieved through a skillful application of economics.

I suggest that there is an equally legitimate area of specialization waiting to be developed and exploited in "non-urban economics," or in "rural social economics" to use Gee's appropriate term. Modern social problems are not exclusively urban, all propaganda to the contrary notwithstanding. And all rural problems are not agricultural. With a broadened specialization like "rural economics," the various subtheories or subdisciplines referred to above, along with others, could be utilized in nonurban applications. In higher education, the product would be a student trained in the same basic economics as the one who specializes in urban economics, but who is now familiar with the applications of this economics in the peculiar institutional setting of the non-urban community in its agricultural as well as its non-agricultural aspects. In research, the product would be the illumination of aspects of the non-urban community achieved through a skillful application and use of the economist's tools.

The Emerging Relevance of Rural Economics

At this point, you may be asking: Why the bother? If we are doomed to see all or substantially all of America concentrated on a few megalopoli within one or two decades, is not any concentration in "rural economics" also likely to face a continuing decline in relative significance? As we all become urbanized, what else is there left for the ruralist?

I shall answer such questions as these by a combination of assertion, conviction, hope, hunch, and hypothesis. We have, as a nation, committed a major blunder in allowing population to become overconcentrated in the cities. This has created for us social disequilibrium of a serious order, which we all must recognize. The error is only in part economic, but I think I can show that there are important economic aspects that have been neglected and overlooked. On simple grounds of efficiency, we probably need to slow down and even to reverse the migration from rural areas to the urban complexes. If I had time and space at this point, I could supply an argument on the basis of elementary economic theory that would, I am sure, convince you of this [see 3]. Let me say only that the argument hinges on the fact that individuals, in making their migration decisions, respond to average rather than to marginal product values in the public sector. The predicted relationship between marginal and average public product values in rural and urban communities strongly suggest that the optimal or efficient population distribution has been tipped too heavily toward urban concentration. Much work remains to be done to document this theoretically-based hypothesis empirically and to convince my fellow economists of my central argument.

So much by way of hypothesis. My hope is that, even for those who do not appreciate the intricacies of our science, we shall witness an accelerating revulsion against the genuine horrors of the modern city. Technology is surely on "our side" here; with rapidly improving telephonic communication especially, the positive perquisites of city life are disappearing. My hope is that we shall, as a body politic, begin to recognize that the concentration in the urban complexes is a singularly acute version of the many-person prisoners' dilemma and that we should all be better off if some deconcentration should take place. Of course, the reversal of population flows will not take place automatically, and we shall not escape from the dilemma by individually organized efforts. The congestion equilibrium of the cities may provide the motivation for increasing numbers of isolated persons to get out, but this will represent no avenue of improvement.

The urbanologists among us have dedicated themselves to the proposition that the congestion-pollution dilemma can be made tolerable by effective leadership and responsible public policy. Even the most ardent advocates of urban life rarely predict the emergence of new utopias in our cities, regardless of the success in securing federal funds. There seems to be a sort of consensus that responsible policy can, at best, prevent further decline and decay. Nonetheless, we must, as practical men and as taxpayers all, face the simple fact that we are, and very rapidly, building up an impressive academic, quasi-academic, and bureaucratic pressure group that will be able to marshall powerful and continuing arguments for the expenditure of billions in and about the urban centers.

Personally and professionally, I do not like this future that I see. I think that we can do better. And I should like to see a massive program aimed at escaping from the genuine prisoners' dilemma of the megalopolis. This program will not emerge so long as various rural development programs, not matter how well intentioned they are, are motivated primarily by the political proclivity to spread the funds around. Effective programs for genuine revitalization of American rural life can emerge, if at all, only when there is a groundswell of opinion to the effect that such programs will be advantageous to all, no matter what location. We should be sophisticated enough to recognize, however, that such a groundswell of opinion does not emerge spontaneously, as if from thin air. It must be developed, nurtured, prepared, and supported by effective academic and quasi-academic dialogue. In effect, I am suggesting that "agricultural economics" and "agricultural economists" transform themselves into the pressure group that is required for this major but exciting challenge.

I acknowledge that I am on treacherous ground here, and especially so because of the general methodological stand I have taken, in this paper and elsewhere. I cannot simultaneously say that the task of the economist is to examine exchange behavior of individuals in all of its institutional ramifications and at the same time say that economists, as professionals, should get into the political affray and begin promoting one particular set of values and objectives. Positive economic analysis and politics, whether partisan or non-partisan, do not mix, and I certainly do not want to be interepreted as lending support here to the intense and accelerating pressures for the politicization of all scholarship in the social sciences, pressures that I think are almost completely destructive, both in intent and in effect. I am not suggesting that those professional economists who are philosophically "agrarian" or "rural" in outlook should organize themselves and try to impose their own version of the world on others. I am, instead, suggesting that some professionally-trained economists, regardless of their own values, devote themselves to imaginatively critical examination of alternative institutional futures, including futures that are less urbanized than those that simple projections now indicate to be inevitable. Of course, those who consider such non-urbanized futures to be desirable will be more inclined to pursue such research. I make no naive claim that science can ever be *wertfrei* in the strict sense of the term. My emphasis is, rather, that imaginatively critical and positive analysis can be applied to non-urban institutional potentialities with possibly dramatic results. In this, I may be expressing a hope rather than a supportable hypothesis. It may be that we shall not escape from the congestion dilemma and that life in the decades ahead will be, at best, "nasty, brutish, and long," to use but a slight variation on Hobbes.

Have we really explored the external economies that are generated by the shift of retirement communities away from the urban centers? Have we examined the potentialities of dispersing our higher educational institutions, and the prospects of accomplishing this and other tasks by fiscal incentives? Why do we need to pay massive sums in aid-for-dependent children to mothers regardless of place of residence? Is not some dispersal of both the old and the young a meaningful objective when federal and state welfare outlays are made? Have we really developed systematically the welfare economics of the family? Is the existing pattern of family life in our urban center sacrosanct, or might it not be possible to move at least some distance toward the institutionalization on a year-round basis of the "summer bachelor" pattern? Has the social and economic stabilization potential of the "second home" been fully explored? And has the full socioeconomic value of the "old homestead" been appreciated?

These are only a few of the questions that might be raised and that might become legitimate areas of research concentration. Admittedly, some of the questions necessarily move beyond economics narrowly defined, into paraeconomics or into areas preempted by other social sciences. Nonetheless, it seems to me worth while for professionally-trained economists to give serious thought to these and many other alternatives. I think that economists are particularly well-equipped to provide analytical leadership in this respect. They can do so, however, only to the extent that they are willing to dig themselves out of their isolated econometric foxholes which seem uninteresting and almost totally irrelevant to those concerned with social order in the large. Despite manifold perversion, economics still supplies us with a uniquely hard-headed and non-politicized approach to social structure. This approach is needed more urgently now than it has been for generations. Without its influence, romantic fools command the center stage, with potentially disastrous consequences. (I challenge any economist who has attended a University of California faculty meeting to disagree with this statement.)

Among those professionally competent economists who have concerned themselves with the larger social issues, progress has been made. No longer do we find many of these men under the romantic illusion that ideally efficient public-governmental programs provide the alternative to market organization. Markets fail, and often notoriously so, but governmental programs also fail, and often even more notoriously. Recognition of this simple fact itself represents intellectual advance. Continued comparison and evaluation of alternative institutions must be made, and perhaps more importantly, an imaginative search for new institutional forms must be encouraged.

In my own very provisional diagnosis, men now desperately seek two related but partially contradictory objectives. They cry out for some community to which they can offer loyalty, while at the same time they seek privacy in an escape from the contiguity of anonymous fellow humans.

The nation-state, as an effective god, has failed. The churches have defiled their traditional role. New institutions have been, and will be, developed to command the loyalties of men. Few among us can look optimistically at the pattern that threatens to emerge with coalescence centered primarily on age, race, innovation in behavioral perversity, and, finally, terror. Perhaps I both exaggerate the seriousness of the portent and grasp at straws of my own prejudice. But radical dispersal of people over space appears almost to be a necessary complement to any policy of hope. Anarchy, whether this be open or repressed, cannot be tolerated in our time. The forces that make for anarchy can only be channelled constructively through significant devolution of power, through effective decentralization of authority, which must embody a spatial dimension. The apostles and advocates of bigness, of concentrated power, of centralized authority, aimed at making tolerable the human pollution of our cities, along with the scientists and scholars who give them advice and counsel will be with us, as indeed they should be. In summary, my plea is for the emergence of scientists and scholars who can become equally equipped to provide useful advice and counsel to those enlightened leaders who will certainly appear to espouse the virtues of smallness, of limited power of man over man, of decentralized authority, of the clean pure air of the countryside, which every man must seek and few men find.

INVITED LECTURE

CHAIRMAN: GLEN R. PURNELL, CANADA DEPARTMENT OF AGRICULTURE

Some Problems of Agricultural Development*

ORIS V. WELLS

I MUST begin by saying something about the background against which this paper has been prepared.

I have for the last eight years been almost entirely engaged in administrative work. Indeed, this is my first Association meeting in nine years (after having attended, I believe, every annual meeting from 1928 into 1959). I serve most of the time as the day-to-day executive officer of the F.A.O. (Food and Agricultural Organization of the United Nations). We are a relatively small organization spending something more than $100 million annually and influencing to a considerable degree additional expenditures for foreign aid or international loan outlays of at least another $250 to $350 million. We are also quite a complex organization, financed from several main sources, employing some 2,200 professional officers assigned to operations or missions in some 100 developing countries in addition to our headquarters staff. We deal with agriculture, including fisheries and forests, and are necessarily as much interested in the problems of processing and trade as those of production. In addition, our assignment relates not only to rural welfare but to nutrition generally. All this keeps us in constant contact not only with the developing nations but equally with the other members of the UN family as well as most of the bilateral aid programs, the voluntary agencies, and the main foundations working in the developing world.

Quite obviously, my assignment is not conducive either to reading or producing much professional literature even though I do occasionally receive a draft paper from John Mellor or some of the other agricultural economists working in the field, and I do occasionally read an article in

---

* I am indebted to a number of my colleagues in the FAO for advice or assistance in developing some of the ideas in this paper, especially Messrs. P. A. Oram and H. Quaix of the Indicative World Plan. The responsibility for the ideas expressed here, however, is mine and they do not necessarily represent the official policy of the FAO. I should also call attention to the fact that the presentation here is in considerable part based on my earlier paper on the same subject, which was presented at the opening session of the Society for International Development at its Milan meeting in June 1967.

ORIS V. WELLS *is deputy director-general of the Food and Agriculture Organization of the United Nations.*

the Journal. But the most of what comes to me is what comes to other aid administrators, and a great deal of it comes through conversations, conferences, and arguments in our governing and coordinating bodies. I do not intend to document these conferences and legislative proceedings except to call attention to the proceedings (which I hope will soon be published) of the Rockefeller-Ford Foundation seminar with some leading aid administrators and UN officials, which was held at Villa Serbelloni, Bellagio, Italy, on April 23–25 of this year. In my judgment, this seminar (which I did not attend) left a strong impression on those who attended it. The Rockefeller group put forward a strong argument for a series of science-based, production oriented commodity improvement programs, centered around work originating from an expanding number of "centres of excellence" while the main Ford presentations, both by former presidents of this Association, F. F. Hill (1951) and Lowell Hardin (1964), dealt with the problems of social and economic priorities and difficulties, including the so-called "second" or "later-generation" problems that come with success.

So Mr. Chairman, Ladies and Gentlemen, what I have to say comes chiefly from my own observation, from watching the daily flow of problems and policy discussions among those administering or assisting aid programs in the developing countries. At the same time, I should warn you of the things that I am not going to discuss:

I am not going to discuss the importance of agriculture in the developing countries nor the necessity of agricultural development in most such countries as an essential to overall economic development. This I take for granted (but I have also presented the argument in detail in my paper at the Centennial Celebration for the USDA in 1962).

I am not going to discuss or argue about how much of the world's population is hungry or, more important, malnourished. There is, or so it seems to me, substantial evidence that the proportions are much too large. As well, there is substantial agreement, as was not the case a scant ten or twelve years ago, that the answer to all development problems in the predominantly rural developing countries is not immediately to be found through industrialization and general education or that it is likely or desirable that food surpluses of a few developed nations can or should guarantee the huge populations of the underfed world against hunger and malnutrition. These things I also take for granted.

Perhaps I should add that I am also not directly discussing Shaffer's basic paper (on institutional obsolescence and innovation) for this meeting, even though I feel I might well have used his title and many of his observations; nor am I discussing the Don Paarlberg thesis that our present rate of technological change (in the western world) exceeds the optimum rate. Both the main thrust of Shaffer's paper and the Paarlberg thesis seem to me to apply to the USA here and now. My concern rather is with the developing world where most of us believe an increased rate of technical change is essential.

Some Key Objectives of Agricultural Development

Before talking about the process of agricultural development, we may well ask what are, or perhaps more precisely, what should be the relevant objectives of the developing countries that may want to achieve a rapid expansion of agriculture in order "to provide a firm foundation" for the accelerated growth of their overall economies. I take these to be:

(1) Assuring the staple food supplies for a population typically growing at 2.5 to 3 percent per annum. For many countries this basically means achieving a faster rate of growth of cereal production. However, the pulses and the more economical sources of animal protein must also be included while, at the same time, wastes should be reduced.

(2) Changing the composition of the national diet to meet the specific requirements of a food policy which emerges from an analysis of the main dietary deficiencies, with appropriate attention to the effects of rising incomes and urbanization. Here the supply of protein is the most crucial problem.

(3) Earning and saving foreign exchange. Shortage of foreign exchange is one of the most serious constraints or "bottlenecks" to economic growth in most developing countries, and most of them depend mainly on agricultural exports as their chief source of foreign funds. Increasingly also, a great many of the developing countries are concerned with the economic possibilities of import substitution.

(4) Encouraging the institutional changes necessary to best move toward the above objectives. But in most developing countries such changes must be made in such a way as to provide a large part of the additional employment for an increasing rural population at least over the next fifteen years or so. This puts the emphasis on increasing productivity through intensification while at the same time helping to create opportunities for employment in the "agro-allied" industries (country based).

The Principles

Over the last 15 to 25 years a great deal of attention has been devoted to the problem of accelerating development in the developing countries. The USA has been actively engaged on a large scale bilateral program ever since President Truman launched the so-called Point IV Program; almost every other developed country has joined in, including the USSR. The UN system, through the specialized agencies and the UNDP, is increasingly involved; and a considerable number of the charitable agencies and philanthropic foundations are heavily engaged, to say nothing of the interest, the activities, and the leadership that now exist in the developing countries themselves. In view of all this, one might believe that there is a good understanding of the problems involved—that the way ahead is clear.

Actually, the problem, stated in terms of averages for the developing countries as a whole, may not seem too difficult to you. That is to say, population in the developing countries is growing at the rate of 2.5 to 3 percent per annum—a rate which is likely to continue for 15 years or more despite the increasing interest in population stabilization. Meanwhile, it appears to me that the most likely target for the average increase of G.N.P. for the developing countries for the UN Second Development Decade (DD2—1970-80) is in the process of being set at about 6 percent per annum. These facts, then, lead to a target of about 3.75 to 4 percent per annum for increased food or agricultural production, as compared with an actual annual rate of increase of about 2.75 to 3 percent over the last decade.

Surely, to many economists and development theorists, increasing an annual rate of growth by 1 percent, from 3 percent to about 4 percent, say, does not seem too difficult. But, in fact, the problem of increasing food production in the low income areas with rapidly increasing populations is an extremely difficult, intractable one. To begin with, we must realize that in such countries 50, 60, 70 or 80 percent of the population are in rural villages and often half or more of the nation's G.N.P. derives from agriculture. Foreign exchange and international aid or loan funds are scarce and, even given the best of management, the assistance that a country can give its population must always be quite thinly spread. New techniques and institutional arrangements must be introduced and usually this involves education: these take time. And in all too many cases, of course, the problem is further complicated by the fact that it must be solved in such a fashion that most of the current population, along with the natural increase, must remain in the agricultural sector.

All this does not mean that substantial progress has not been made nor that some general rules are not beginning to emerge. Some nations, as well as particular areas in other nations, have indeed done very well. Looking at these nations, as well as our own experience in FAO in working with many nations, has led me to suggest a provisional set of general principles toward which I think we should be moving—principles which I think are being more and more used in planning and appraising requests for assistance in the agricultural field. These are:

Principle one:

Small-scale, piecemeal technical assistance is simply not a sufficiently strong tool.

Stated so simply, perhaps many of you might agree; but the fact remains that small scale technical assistance, which can of course be a valuable part of any well planned, well executed program, is most appealing to many people for many reasons. It provides the material for good human interest stories; it is relatively cheap; it satisfies our desire to tell other people how to be more industrious; and, in many cases, it does pay off with a good substantial multiplier effect. Unfortunately, however, the adoption of one or only a few technical improvements in a few selected locations does not materially increase aggregate productivity or overall production as a whole. Conversely stated then, principle one leads to principle two.

Principle two:

It is increasingly evident that farming systems as a whole need to be substantially altered or redesigned in many areas, that what is needed is an integrated "package" rather than a "piecemeal" approach.

As one of my friends who loves to write about economic development said some time ago with respect to Mexico, where the development and introduction of improved seed stocks have made such an outstanding contribution, "Whatever the crop, plant breeding was just one step. The Mexican program gradually evolved into a balanced effort with geneticists breeding better plants, pathologists fighting disease, entomologists warring on insects, soil men rejuvenating the tired earth, specialists improving the livestock. For example, the higher yields required more plant food, and fertilizer was both scarce and expensive. This triggered growth of a new Mexican fertilizer industry." And since I want to return to the time factor later, perhaps I should say that the original work by the Rockefeller Foundation about which my friend writes started not two or three but 26 years ago—at the same time that the FAO Preparatory Committee was organized (1943).

The advantage of developing integrated "package" programs rather than trying to introduce piecemeal technical assistance was first brought to my attention by Dr. Salter of the old Bureau of Plant Industry in discussions that we had concerning American agriculture immediately following World War II. This idea is now making substantial headway in the developing countries. Further, it is apparent that something more than the technical knowledge of the better combinations of farming practices is necessary. To know which seed strains are best means little unless arrangements for producing and distributing such seed can be worked out. To know that one needs particular kinds and quantities of fertilizer for particular crops is not the same thing as having the fertilizers. And even if farmers know how to increase productivity, they are not likely to do so without knowing whether or how they will be rewarded for the extra costs and efforts involved. So this leads to principles three and four:

Principle three:

In addition to developing the necessary "package" of new practices or revised farming systems, ways and means must be found of supplying the necessary production requisites or capital inputs, many of which must come from the outside.

Principle four:

At the same time, ways and means must be found of motivating farmers to adopt the new practices or systems.

Principle three of course explains the current interest in assisting or working, wherever possible, with financing agencies, including, wherever practicable, private business, as well as the need for increasing supplies of production requisites—that is, fertilizer, pesticides, and farm machinery—moving through bilateral and multilateral aid to the developed world.

And it is principle four that takes us into a most difficult territory. How does one transfer technical knowledge to individual farmers who have a long ingrained acceptance and sophisticated knowledge of their traditional practices? How does one change not only practices but tenure arrangements in such a way as to effectively increase the incentives for improvement? How does one organize credit and marketing systems that will function at least reasonably well in the interest of the great mass of small scale farmers? How does one develop some reasonable, not too costly a system of ensuring minimum prices for farmers' products? Such questions as these lead into everything from cooperatives to agrarian reform, supervised credit and price support—all measures that require good central planning and usually strong continued governmental support (as also does the team or package approach to the technical or physical side of the problem).

Principle five:

Ways and means must be found of assisting or motivating the governments of the developing countries in giving the necessary priority to planning and actually carrying forward a sustained effort to increase agricultural productivity.

The reasons for this principle are obvious, given the scope and scale of the efforts that many of the developed nations must devote to food and agriculture. I mention it, however, in order to emphaize two points. The first of these is the need for assisting developing countries in their agricultural development planning, an activity which should have high priority. I also mention this problem of assisting or motivating governments because it means the aid-giving agencies must work with governments, must have personnel stationed at the actual seats of governments who work with the people mostly concerned with agriculture as well as with the other aid or assistance agencies working within the particular country; in short, the bulk of the work of increasing agricultural productivity falls on the farmers and governments of the developing nations, not on outside experts. Our experts are not, and should not be, plantation overseers or managers. Rather, their business is to help the country find the right answers, make the right plans, and develop within itself the competence to carry forward the necessary work.

Some Related Problems

So much for my suggestions as to the general principles against which one should make plans or appraise proposals in connection with rural and agricultural development activities in the developing countries. I now want to say a few words about food aid and family planning and then turn to what I call the "intractable" problems, that is, the constraints or conflicts that for the time being must be endured, since immediate solutions even in terms of theory are by no means clearly apparent.

So far I have been talking almost wholly about the problems of increasing indigenous food production of the developing countries. Some may interpret this as meaning that there is no need for continuing food aid to the developing countries over the next several years. Quite the contrary; despite the fact that there have been no massive crop failures in the last year or two and despite the so-called "miracle grains" which are now of great interest in the Far East, the fact remains that substantial amounts of food aid should continue to move to the developing countries for a number of years ahead. I think the governments of both the developed and developing countries recognize this, not only in view of the increasing volume of surpluses both in North America and Europe, but also the recent decision to extend the World Food Program on a continuing basis, the fact that the current $200,000,000 World Food Program pledging target will likely be oversubscribed, and the agreement of both the FAO Council and ECOSOC to advance the pledging target to $300,000,000 for the period 1970–71.

The problem as I see it is not whether food aid might continue, but how such aid might best be used. There are times and places, and such times and places have been much too frequent in recent years, where emergency food aid is essential. We do not want people to starve, but at the same time we want the rehabilitation process to move as fast as possible. We want to see that food aid, as far as possible, assists in the economic development of the recipient nations. At the same time we want to see food aid extended in such a way as not to discourage increases in indigenous food production.

I now come to the problem of family planning. Surely the population explosion makes this a priority problem. I recognize the social difficulties and the time factor involved, and I am certainly not suggesting that current technological prospects are not such as to offer a decade or more of time to work on this problem. But in my opinion recent developments only buy us time, and I agree that the problems of population growth will not disappear, that if we wait too long our options will be overtaken by events and that we should move as fast as possible. Family planning is not designed to destroy things, but rather to save them. It is not my purpose to argue this thesis at any length. Fortunately, it seems there is now a wide and increasing agreement as to the necessity for family planning and a fair chance that considerable progress may be made over the next two decades toward bringing the population explosion under some degree of control.

I now come to the intractable problems, that is, the problems that one simply lives with because there are no immediately satisfactory solutions. The first of these has to do with education. Certainly training and education are important parts of any development process, and there are a considerable number of people who argue that the basic solution to most development problems lies in creating educational and training institutions or arrangements, rather than immediately working on resource surveys, pre-investment analysis, and immediate action programs within the developing countries. Indeed, at the Bellaggio seminar, F. F. Hill indicated that if this were the year 1850 instead of 1969 he would feel that assistance to developing countries might be largely limited to educational activities, leaving it to each country to work out its own salvation in other fields; but this is 1969, and the population explosion forces priority to other problems, including food production. In fact, the developing countries themselves insist on action now and the problem is how to combine education and training into an overall development program.

Now, a second special problem: the staggering difficulties set by dense rural populations which continue to increase at a rapid rate. In those areas and regions where the hunger problem is most acute, ways and means must be found for increasing agricultural productivity, while at the same time maintaining on the land dense populations as well as a substantial portion of their natural increase over the years ahead. This also leads a considerable number of people to insist that the greatest single problem is the problem of rural employment. But creating jobs by simply spreading work is not a satisfactory solution, production must be increased. Ways and means must be found to increase agricultural productivity in order to make life in rural areas more economically rewarding and, indeed, in order to support the current or increasing populations at any reasonable standard. Also, it seems to me that ways of raising living standards so as to make life more attractive must be found over and beyond the problem of making farming itself more economically rewarding, and at the same time ways should be found to involve rural people themselves in decisions that affect themselves and their institutional framework. This problem of maintaining or increasing rural employment substantially conditions the technical solutions that may be suggested in many countries. I am not saying such solutions are impossible; in this connection, we are inclined to talk about the "Japanese pattern" in view of what the Japanese have been able to accomplish in terms of increasing agricultural productivity, while still maintaining a small farm technique and a relatively heavy farm population.

There is also a foreign trade problem, one I need not discuss at any length with agricultural economists. The source of foreign exchange for investment purposes in the developing countries is chiefly from exports of agricultural commodities from the developing countries themselves (with the exception of a few that happen to have oil or special mineral resources). But over a large portion of the developed world, agriculture is now so productive that the developed countries are large exporters of most temperate zone products, while at the same time synthetics and other substitutes are also cutting into many traditional markets. Most of the developing countries are seeking access to additional foreign markets and are hoping through commodity agreements or other trade arrangements for some increase in return per unit of farm products exported. At the same time, many of the developing countries are actively studying the problem of import substitution, of producing as much of their own needs as possible, in order to economize in the use of scarce foreign exchange, or in order that their foreign exchange may be used for investment purposes rather than to pay for imported food.

Finally, I come to the time factor, to which I have already referred several times. The adoption of new techniques, the revision of farming systems, and the motivation of farmers and governments, must often be accompanied by a substantial amount of training and education. Also, the finding or accumulation of the necessary financial resources can often involve a considerable amount of time; so most planners and most economic development theorists agree that a substantial amount of time is needed to plan and execute a successful development effort, but time, simple time, is a commodity of which most administrators and political leaders are lamentably short. And one of the driving forces behind the administrators and political leaders, of course, is the fact that time soon runs out for their hungry or poverty-stricken people. One of the most difficult problems in planning agricultural development activities is to find an acceptable mixture of short-term activities that accomplish what one can this year and the next, while at the same time understanding that any successful solution depends upon planning well now for efforts that must continue over a substantial number of years ahead.

ECONOMICS OF INPUTS

CHAIRMAN: JAMES NIELSON, WASHINGTON STATE UNIVERSITY

Structure of Input Supplying Industries and Techniques of Analysis*

DALE C. DAHL

THIS paper surveys the character of structural change in selected farm input industries, stresses the need for increased economic research in these factor markets, and presents some encountered and anticipated research problems and techniques of analysis.

G. Edward Schuh has provided a useful review of economic research since 1950 in the agricultural input markets [17]. His summary emphasized the relative lack of economic research and policy attention to these markets. Schuh's research review was organized around two concepts of structure: *market structure* research and *structural relation* research.[1] His annotation ranged the full spectrum of productive factors.

This paper is more limited in scope. It deals with U.S. feed, seed, petroleum, fertilizer, pesticide, and farm machinery markets.[2] Further, it tends to stress market structure research problems. This is because of particular inter-industry organizational developments during the 1960's. The substantial structural adjustments noted in these markets apparently have helped generate expanded research interest in the purchased input industries.[3] Recent emphasis in both market structure and structural relation research by the Economic Research Service and several state experiment stations suggest this increase.[4] Most recently, 14 states have joined a

---

[*] The author is indebted to his colleagues at the University of Minnesota and to Paul Nelson of ERS, USDA.

[1] "For our purposes, let us refer to the econometric research which attempts to develop equations describing the behavior of economic entities as *structural relation* research. That research that has as its immediate aim the evaluation of the performance of a market or a description of its characteristic will be referred to as *market structure* research" [17].

[2] Other papers in this session of the meeting justify exclusion of labor and credit markets; the land market is avoided to emphasize purchased farm input industry interrelationships.

[3] Another leading reason, if not most important of all, is the decision to extend the use of Hatch funds under the "20 percen marketing" rule to the input markets.

[4] Within ERS, two research units have been most active: Farm Resource Branch, FPED, and Input Marketing Research Group, Pricing and Competition Branch, MED.

DALE C. DAHL *is associate professor of agricultural economics at the University of Minnesota.*

Western Regional project entitled "Agricultural Factor Markets and Buyer-Seller Procurement Strategies" [8].

It is my contention that this expanded interest in factor market research is well justified. The patterns of organizational change, of market conduct, and of potential performance impact may be the most significant in the agricultural economy today. Let us review some of these changes.

Input Industry Structure

General patterns

The organizational changes in the industries that produce and/or distribute feed, seed, fertilizer, petroleum, pesticides, and farm machinery, while separately unique in many respects, also have a general uniform pattern. Each input-defined industry has decentralized its manufacturing (or formulating or mixing) phases in a geographic sense but has integrated manufacturing and distribution functions so as to yield larger local outlets than before. Further, each input increasingly is sold as part of a product-service package, increasing the extent of product differentiation of inputs and compounding difficulties in farmer purchasing decisions.

Another general characteristic of companies manufacturing farm supplies is increased diversification or conglomeration.[5] Of the input manufacturing industries reported in the *1963 Census of Manufacturers* (prepared animal feeds, agricultural chemicals, and farm machinery) the "specialization ratios" generally exhibited declined between 1947 and 1963, while "coverage ratios" increased over the same period [10].[6] This means that these input industry establishments classified by their primary product increased their production of secondary products over the time period. Thus, they became more diversified. It further suggests that increased industry concentration occurred during the same period.

The interaction of distribution systems among industries is clear but not as well documented. Two general distribution schemes are being tested and exist side-by-side in many input markets. Highly specialized outlets compete with highly diversified outlets. For example, fertilizer blending plants rival "farm service centers" that attempt to combine fertilizer distribution with a variable range of inputs, depending upon the farming area. A continuous search is made by input industry companies to find the "right" product-service package. It appears that more than one package type is demanded.

---

[5] The terms "diversification" and "conglomeration" are synonymous to many authors. This is one such author.

[6] "Specialization ratio" is defined as the value of primary products shipped by an industry divided by the value of primary and secondary products shipped by that industry. The "coverage ratio" is the value of a primary product shipped by an industry divided by the value of a primary product shipped by all industries.

Two structural developments deserve more specific treatment: (1) the petroleum-agricultural chemicals industry interactions and (2) decentralization in the feed industry.[7]

Petroleum and agricultural chemicals

The following statement suggests the technical and economic connections between the petroleum and agricultural chemical industries:

> . . . the interest of the petroleum industry in agriculture extends far beyond supplying farmers with fuel. The industry also owns the basic sources of natural gas, a major raw material in producing ammonia for fertilizer, and accounts for nearly 40 percent of the synthetic anhydrous ammonia production capacity. Furthermore, a number of petroleum firms have diversified into fertilizer mining and manufacturing operations in recent years. Petroleum hydrocarbons are also the base for many of the present-day agricultural pesticides, and for urea, an important nitrogen product used for fertilizer and feed [2].

During the later part of the 1950's and to the present time, a competitive "battle of giants" was recorded in U.S. agricultural chemical markets. Major petro-chemical companies entered into the production of synthetic anhydrous ammonia, only to be faced with a lack of retail outlets for their product. It became clear that either the more volume-oriented distribution systems of the cooperatives would be required to handle the increased quantities of fertilizer or a new distribution system must be developed [1]. The latter strategy was followed when bulk blending of dry materials became technically feasible in the early 1950's [4].

This move to by-pass the traditional distribution system for fertilizer was countered by the cooperatives. They responded by building their own dry blending facilities and integrating backward into the primary production of anhydrous ammonia. These competitive strategies netted the cooperatives a 14 percent share of U.S. anhydrous ammonia production and a 30 percent share of all fertilizer sales in 1966 [13].

These technological and competitive developments reduced manufacturing and distribution costs, lowered the price of fertilizer dramatically, and encouraged substantial increases in farm uses of plant nutrients. Whether the crop response netted an income gain to farmers is debatable; the adjustments in the fertilizer industry left excess capacity at localized geographic points [9].

Cooperatives have continued to respond to competitive pressures from private firms in pesticides. Cooperatives have integrated backward into pesticide formulation. They now account for 15 percent of total sales [12].

---

[7] I tend to agree with George R. Allen that these are the most significant developments in the purchased farm input markets in terms of their impact upon farmers and the input manufacturing and distribution system [6].

Decentralization in feed

Substantial increases in the consumption of commercial feed have been recorded in recent years. It was estimated that 60 percent of the four principle feed grains moved through commercial channels in the 1960's [3].

Patterns of competitive conduct have been characterized by the "contract movement" in the 1950's and the location of satellite manufacturing facilities in areas of heavy feed consumption in the 1960's [15]. In 1947 there were 2,688 prepared animal feed establishments in the United States; these dropped to 2,292 by 1954 as contractual efforts by larger firms urged the exit of many smaller mills. The trend to satellite plants is evidenced by an increase in establishments from 1954 to 1963 (to 2,590) [10].

Cooperatives have played a significant role in feed manufacturing, accounting for between 20 and 25 percent of sales in recent years. Cooperatives have supported extensive product differentiation by offering their own brands and special services. If taken as evidence of firm rivalry, this agrees with Padberg's judgment of good industry performance [16].

Retail market structure

The adjustments occurring in agricultural chemical and feed markets show trends of combining manufacturing or mixing activities with retailing and wholesaling functions at localized geographic points. This development, as indicated previously, is coupled with either forward integration to the retail level or backward to the level of primary producer or manufacturer. While these examples serve to illustrate a higher degree of input specialization in a product sense, the trends are contrary to more recent developments in farm service center activities. Like many terms, "the farm service center" has come to have various meanings to different people. One definition is "a grouping of two or more product or service activities at a retail level for the purpose of merchandizing farm inputs." Such a definition has little operational value in research. Most companies who deal in a singular product offer sufficient numbers of services to claim they are a farm service center. As we individually conjure up our own stereotype of a farm service center, we may think of some "complete" complex of shopping center type activities for farm production inputs under singular ownership. Of course, the particular combination of enterprises that go into a farm service center depends upon the type of farming activity present and judgments regarding economies of distribution and processing and sales potential around the center itself.[8]

---

[8] As discussed by Ronald Aines at the NCR-20 Seminar on "The Economics of Conglomerate Growth," Kansas City, April 30, 1969.

A recently advertised concept of the farm service center is exemplified by National Farm Stores of Minneapolis. This organization, financed by Litton Industries, manages a farm family consumption mart and hardware store. It builds, owns, and leases buildings to house petroleum, fertilizer, feed, seed, machinery, and other agricultural services and products to other companies.[9] Such an arrangement has obvious advantages over a single-owned complete farm shopping center. It minimizes the amount of investment needed, takes advantage of specialized managerial talent already existing in the several industries, and spreads the risk of enterprise failure.[10]

Some input market researchers have questioned whether the farm service center is likely to be a major farm input retail outlet in the future. The hypothesis is that most farm service centers are frequented by smaller farmers. The larger farmers purchase their inputs in large quantities from wholesalers or directly from the manufacturer. If this hypothesis is true, purchasing patterns existing with larger operators now may well be purchasing patterns that will exist for a very large segment of agriculture in future years. A counter hypothesis merely points out that the multi-product, multi-service cooperative is now a form of service center that already discriminates among buyers; it sells large quantities of inputs to larger farmers at lower costs.

Market conduct

A study recently completed at the University of Minnesota described the character of firm strategies involved in dealing competitively at the manufacturing or primary producer level of input marketing activity within an industry and between industries [14]. This study also characterized and rationalized economic behavior in negotiative or across-the-market relationships between the manufacturers and the wholesaler/retailer customer with whom they dealt. An attempt was made to relate observed behavior patterns to the market or industry structure that existed. This reverse order procedure of attempting to describe patterns of market conduct and then ascribe these to structural conditions in the market, resulted in comparable relationships that might otherwise have just as easily been found by looking at structure first and conduct second.

One aspect of market conduct in the input industries of particular note is the systems orientation (rather than product orientation) as an operational element. As pointed out by Ken Farrell [11], the Food and Fiber

---

[9] As discussed with Darrow R. Beaton, General Sales Manager, National Farm Stores, Inc., Minneapolis, Minnesota.

[10] Another definition of a farm service center was presented to me some time ago by a small town businessman who said, "A farm service center? Say, that's what my home town is, isn't it?"

Commission provided evidence of a systems orientation in the input markets and trend toward broadened product and service portfolios. In the case of manufacturing, according to Farrell, the petroleum-rubber complex devotes 20 percent of its total assets to the production of agricultural business services and products; motor vehicles and parts, 15 percent; and the chemical industry, 10 percent.

This type of thinking also seemed to prevail in the study of 57 major farm input manufacturers who ultimately sell their products to Minnesota farmers [14]. It was further clear from this study that maximization of sales volume and increases in share again show up as a major motivational force. This, of course, is consistent with more recent theories regarding technostructure and corporate incentives for growth and power.

Input Industry Analysis

Research needs

The need for economic research and policy orientation in input industries is quite general. Various people have made suggestions for research studies; most notable among them, Willard F. Williams [20], who proposed a broad-based approach to the study of the characteristics of farmer demand for agricultural inputs. On the basis of a survey of agricultural supply industries, Williams found that most industries are having considerable difficulty in determining farmer consumer demand characteristics. Within this context, Williams also stressed the need for more adequate market information for the farmer-buyer. Other studies have demonstrated a serious lack of knowledge on the part of farmers purchasing many types of agricultural inputs [5].

Another significant area of research encouraged by Williams is farmer demand for services. Perhaps one of the more recent studies in farmer demand for services was done at Harvard University, dealing with farmer use of computer services [19].

Additional research recommended by Williams includes studies of the distribution patterns and practices in the different farm input markets, cost, margins and price index studies, and the study of economic relationships in a systems approach.

Additional recommendations have been made by Paul Nelson, and others are being initiated by members of the Production Resources Branch of the Farm Production Economics Division of ERS.[11] Some of these recommendations include development of situation reports for each agricultural input, development of an "input bill" similar to the marketing bill now used on the product side, and studies of various grading systems that might be employed to permit farmers to judge the quality of inputs purchased. A more complete market news system to identify input prices at different point locations in an area also has been suggested.

---

[11] As discussed with Paul E. Nelson, Velmer Davis, Ronald Mighell, and David Harrington, ERS-USDA.

Technique of analysis

Willard Williams properly points out some of the inadequacies of using market structure research in a traditional sense [16]. First, this technique of analysis as generally employed is not inherently problem oriented. It is not generally directed toward well-defined, carefully stated problems with specific goals. Secondly, this technique of analysis, while public policy oriented, does not provide the kind of answers useful in public policy administration. While both of these charges are correct, I am sure that Williams would agree that market structure analysis, depending upon the researcher, *can* be problem oriented and could be policy administration oriented as well.

While I believe a certain amount of research to acquaint one's self with the industry may be justified, piece-meal descriptive studies attempting to describe a dynamic industry at different points in time will yield few satisfactory results.

The nonadditivity of marketing research results in previous product market research was clearly suggested by Jim Shaffer [18]. This shortcoming could easily repeat itself in input marketing research as well. Therefore, I embrace some of Shaffer's thoughts. He states that certain aspects of research in any area should not only be problem oriented and policy directed, but also should be thought of as being carried on by teams, consortiums or task forces. One technique that could be used to encourage task force type results and still retain a high degree of individuality would be to require that each research project headed by an individual or a government agency have assistant project leaders from related and outside agency groups interested in the problem. At the experiment station level this could be made operational, for example, by requiring that no research project be approved unless three assistant project leaders are named along with the person submitting the project for approval. The assistant leaders would also be held accountable for the results of the project.

Clodius and Mueller [7] list some of the significant problems in dealing with market structure research. These problems include disclosures of information given in confidence and unwillingness of firms to indicate that they have in fact been guilty of antitrust violations. One technique used in a Minnesota study was to obtain information about firms by asking questions of their competitors [14]. Firm A may well be willing to talk about the competitive practices of firms B, C, and D. A reasonably good picture of market conduct may result if firm B agrees with A as to the conduct it attributed to firms C and D.

The emphasis on market structure research method here should not imply a preference of technique. Its stress is founded upon previous discoveries of a general lack of perfection in the agricultural input markets. Where analysis permits, other established research techniques should be used.

Conclusions

This paper has demonstrated that only recently has there been an increase in economic and market structure research activity as it relates to certain purchased farm input industries. The recent flurry is due to a change in funding availability and organizational changes, resulting in altered market conduct and performance in these input supplying industries. Of particular note are the adjustments that have occurred in the agricultural chemical markets and in feed manfacturing. A broad list of research activities is needed, ranging from demand studies for inputs and services to systems analysis to market structure research. I hope that from our experience in the product market that we can conduct input market and industry research to provide "needed" answers and additive results about important economic relationships on the farm supply component of the agricultural economy.

Concepts of Finance Capital for a Capital-Using Agriculture

C. B. BAKER AND JOHN A. HOPKIN

IN 1959, 1.2 million farms in the North Central Region, using $21.6 billion in non-land capital and $62.7 billion in land and buildings, produced $10.0 billion of output [5]. Had farms been organized in the region to produce at a minimum cost, 741,000 farms could have doubled this output with the same investment in land and buildings and with $28.6 billion in capital. The results would have been disastrous. The market failed to clear all of the *actual* 1959 output. Had the output been constrained to a "market-clearing" level, 306,000 cost-minimizing farms in the region would have used $12.2 billion of capital and produced $9.1 billion of output.

This summary of results is instructive in that it indicates the puzzle one confronts in projecting capital use in agriculture. Changes in technology have clearly increased the capital required per successful farm. But to project increases in total capital on the basis of technological change alone seriously overestimates total capital requirements. In fact, estimates of 1980 capital requirements that take market clearing into account show a *reduction* in non-land capital of about 46 percent, relative to 1959. The value of land and buildings declines by about 3 percent. But *per farm*, non-land capital increases by 96 percent; land and buildings, by 253 percent.

Our central concern is with the financing of the individual farm firm. Capital management affects the rate of firm growth, through leverage, and the vulnerability of the firm, through liquidity. Capital accumulation constitutes a major form in which farm earnings occur and a major drain upon farm liquidity. A farmer may earn at a satisfactory rate, accumulate an equity in assets, and yet suffer from a low level of disposable income. On the other hand, to divert income from capital accumulation to consumption purposes may so retard a farmer's growth rate as to jeopardize his ability to survive in the dynamics of a capital-using agriculture. Such is the puzzle that faces the farmer in today's agriculture.

Our purpose is to explore the effects of leverage and liquidity on the growth characteristics of the farm firm, the influence of credit on equilibrium of the firm, and the implications of such an equilibrium for resource allocation, firm growth, and achieved levels of income and net

---

C. B. BAKER *and* JOHN A. HOPKIN *are professors of agricultural economics at the University of Illinois.*

worth accumulation. We will conclude with a resumé of policy issues generated by structural changes in agriculture that in turn are the result of management response to economies available in finance capital.

Levered Growth

It is common to measure growth of the firm either by increments in rate of income flows or in equity of the firm. The normative ideal would be a composite that reflects the increment to utility of the firm operator. Equity seems to be a reasonable welfare proxy for the operator who owns assets of the firm, either totally or subject to debt. It may not be for the operator who leases a substantial fraction of the firm's assets. For the latter, equity may be more plausible if it includes, as we do, non-farm assets as well as farm assets. Having selected equity as the growth measure, it seems more convenient to define leverage, L, as the ratio of debt, D, to equity, E, where E is the difference between the value of assets, A, and D [12].

Let the annual increment in equity be given by

$$(1)\ g = (rA - iD)\,(1 - t)\,(1 - c)$$

where r = rate earned on assets in the firm, net except for interest and taxes,

i = rate paid on debt,
t = rate paid in taxes on returns, and
c = rate spent on consumption out of firm earnings.

It is convenient to express growth g' as the annual percentage change in equity, given by

$$(2)\ g' = [L(r - i) + r]K,^{1}$$

where $L = D/E$, the chosen measure of leverage, and

$K = (1 - t)\,(1 - c)$, the percent of earnings remaining after consumption and taxes.

Thus g' is determined by r and L, given the rates of consumption, taxation, and interest. We shall later modify i. We now explore briefly some of the implications of (2) in its present form.

In Table 1 we show g' for several values of r and L. The values likely include many real-life conditions in a farm firm. The first column of Table 1 confirms that the growth rate of a firm is unaffected by leverage

---

[1] (2) is derived from $g' = \frac{\Delta E}{E} = \frac{rA - iD}{E}K = \frac{r(D + E) - iD}{E}K$
$= \frac{D(r - i) + rE}{E} = [L(r - i) + r]K.$

when the interest rate equals the net earnings rate on assets. The growth rates in this column are less than the earnings rate of 7 percent by an amount equal to consumption and taxes.

The first row shows the growth rates for a debt-free operator at each of the earnings rates indicated in the column headings. At $L = 0$, the growth rates are wholly determined by the earnings rate, given the consumption-tax factor. g' is less than r because of the dampening influence of consumption and tax payments. A reduction in either would raise the growth rate. An increase would reduce it.

Table 1. Growth rates (annual percentages) implied by alternative leverage, *L*, and rates of earnings, *r*: consumption, tax, and interest rates specified at .4, .25 and .07, respectively

L \ r	.07	.10	.12	.14	.16	.18	.20	$g' = r(KL+K) - KLi$
0	3.15	4.50	5.40	6.30	7.20	8.10	9.00	$= .45r$
.5	3.15	5.18	6.53	7.88	9.23	10.58	11.93	$= .675r - .01575$
1	3.15	5.85	7.65	9.45	11.25	13.05	14.85	↓ $= .9r - .0315$
1.5	3.15	6.53	8.78	11.03	13.28	15.53	17.78	etc. $= 1.125r - .04725$
2	3.15	7.20	9.90	12.60	15.30	18.00	20.70	$= 1.35r - .0630$
2.5	3.15	7.88	11.03	14.18	17.33	20.48	23.63	$= 1.575r - .07875$
3	3.15	8.55	12.15	15.75	19.35	22.95	26.55	$= 1.8r - .0945$

A conservative borrower might limit his debt to half the value of his equity ($L = .5$). Results in terms of growth rates can be read from the second row of Table 1, for specified rates of net earnings. Even this small leverage can be seen to influence growth rates, especially at higher values of r.

Conventional lenders are likely to limit the borrower to a debt level about equal to his equity. That is, $L = 1$ may be a rough approximation of limits faced by a farm operator who restricts his use of credit to conventional lenders and debt instruments. The third row reveals a gain in growth rates that is perceptible at all rates of earnings.

The operator willing to use a land purchase contract may attain a value of $L = 2.5$ if non-real estate lenders do not discriminate against him in financing his other assets. The lending limit for non-real estate borrowing is assumed at about a dollar of debt per dollar of equity. The growth rate at this value for L exceeds net earnings rate, r, when the latter reaches levels of 14 percent or more.

Why not strive for still higher leverage values? The answer is fairly obvious, especially for the proprietor firm. The operator likely will have exhausted his credit on conventional terms at between 1.0 and 2.0 and almost certainly at 2.5. More borrowed funds would entail use of higher cost lenders who are willing to assume higher risks in return for higher interest rates. It can no longer be assumed that i is a constant with respect to L.

Other limitations also are readily apparent. As incomes increase it is likely that the tax rate, t, will increase. On the other hand, the rate of consumption expenditures may well decrease. Hence a constant value may reasonably approximate the combined effects of c and t.

Our model represents a firm with constant scale at alternative combinations of debt and equity. Empiric evidence suggests that constant returns may be a good approximation over wide ranges of production conditions. But it probably is not safe to assume r constant for some larger sizes implied by higher values of L.

A more serious limitation is found in a subtle point relevant for research in financial problems. The concept of leverage does not include costs other than interest. But to exchange credit for loans (that is, to increase L) entails a loss of liquidity. Held in reserve, unused credit provides liquidity with which to meet the effects of an unfavorable event in production or marketing. Hence we need, finally, to develop a concept of liquidity as an essential element in financial management.

Credit-Liquidity and Equilibrium

Liquidity is an attribute of the financial organization of the firm [3]. We conceive the value of a firm to be the amount that could be obtained from sale of the firm as a complete aggregate. The sale of asset(s) within the firm will in general reduce the value remaining in the firm by as much as or more than receipts from the separately sold asset(s). If the cash acquired from separate sale equals exactly the loss in firm value, one concludes that the asset(s) is(are) perfectly liquid.[2] For those assets whose sale would contribute less to cash than to a reduction of remaining firm value, the asset(s) is(are) less than perfectly liquid. So conceived, assets can be arrayed in terms of their contribution to the liquidity of the firm.

Many assets of the firm are not incorporated into the firm's asset structure in expectation of separate sale. Yet they can be used as a partial basis for credit through exchange of a part of the bundle of property rights for a loan. This is the part to which we have assigned the concept of credit. Credit may depend on more than the collateral value of the firm's assets, but it is reasonable to assume that assets contribute to liquidity in the form of "credit" as well as in the form of potential sale. Indeed for many assets, the credit form of liquidity is more available and more likely to be used than is the sale form of liquidity.

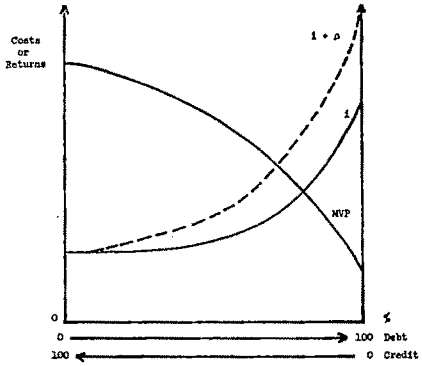
Just as the concept of leverage lacks an explicit cost associated with use, liquidity lacks an explicit return associated with its use. Indeed, the two concepts are most useful in an equilibrium frame of reference. Leverage operates as a multiplier with respect to the marginal value product of resources added to the firm. If the marginal value product is positive, no explicit limit terminates the addition of financed assets. But if liquidity is valuable to the firm, increasing debt relative to equity reduces credit left to finance capital assets or operating expenses in the future, or to meet unforeseen financial problems. It is reasonable to argue that as credit is reduced, remaining units of credit acquire successively higher values. That is, credit is used at a cost that increases as debt increases, even though the rate of interest may remain constant over wide ranges of credit use.[3] Liquidity and leverage are concepts of central importance in the financial management of the farm and credit is an important component of a firm's liquidity.[4]

---

[2] The time required for sale may influence the price expected for either the separate asset(s) or for the farm as a whole. To incorporate this property of the exchange implies that we assume time that is comparable as between the two cases.

An equilibrium in credit-use is depicted in Figure 1. Increments to costs or returns from credit use are shown on the vertical axis, units of credit or debt on the horizontal axis. The curve labeled MVP describes increments to returns from resources financed with loans. The curve labeled *i* describes increments to loan costs from added units of debt. Its slope reflects the presumption that the farmer faces higher-cost loan sources as his debt increases. The quantity, ρ, is the value ascribed by the farmer to a unit of credit held in reserve. Its slope reflects the presumption that the value of credit increases as successive units of credit are absorbed by loans.

Figure 1. Firm equilibrium in the use of credit



---

[3] Interest rates too may increase as the borrower exhausts first low cost sources and then higher and higher cost sources. The point is that the opportunity cost *to the borrower* increases, whatever the behavior of lenders available to him, through their behavior is certain to affect the objective value he places on unused credit.

[4] The effects of credit management on optima in the firm are explored in theoretical terms in [1] and [2].

Finance and Within Firm Resources Allocation

The effects of credit-use on production equilibria of the farm firm have already been outlined [1]. In summary an optimum combination in resource use is achieved when

$$-\frac{dX_2}{dX_1} = \frac{p_1 + f_1}{p_2 + f_2}$$

where p_i is the price of input X_i, and

f_i is the marginal cost of financing a unit of X_i, including the cost of liquidity lost in the transaction.

There is little empiric reason to suppose that $f_1/f_2 = p_1/p_2$. Hence the incorporation of credit-use, *whether or not* actual borrowing occurs will influence resource combinations. Similarly, where lenders favor one enterprise (product) relative to another, the optimizing product combination is altered. The resulting optima are determined not only by product price ratios but also by farmer expectations on lender behavior with respect to alternative enterprises.

In a behavioral context one must modify the hypotheses commonly used so as to include aspects of credit and finance capital. It is plausible to suppose that a growth-conscious farmer is aware of the value of reserved credit as well as of leverage in growth. He will be concerned with growth in credit, as in other resources, allocating credit to high payoff usages, especially as successive quantities of credit are withdrawn in borrowing. Indeed, with the increasing sophistication generally predicted for tomorrow's commercial farmers, these concerns will likely increase relative to other problems and become more and more explicit in the farmer's allocative calculus. Hence financial components will become increasingly relevant in models used in prescriptive and behavioral research as well as in education and counselling with farmers.

A farmer's credit is differentiated in terms of loan source as well as by farm characteristics. Hence credit management relates to source as well as use of credit. Farmers appear to be shifting from specialized suppliers of finance capital to input merchandisers to finance important aspects of their organizations. Is this to be explained by convenience? Or is it to be explained by greater credit tolerance of the input suppliers because of their stake in merchandising? Or does the farmer conserve his "general purpose credit," available from the supplier of the finance capital, because of its liquidity value? All these explanations are plausible, though clearly some may be more useful than others as behavioral explanations of the farmer in the act of financing.

Interfirm Complementarities Relating to Finance

Much of the new technology in production creates possibilities for economic gain from specialization, making production more intensive in terms of both capital assets and finance capital. In response, markets develop outside the farm firm for many products and services previously identified as part of the farming operation. The industry is thus segmented into many economic stages.[5] By definition, each firm has at least one economic stage.

Changes in marketing, on the other hand, have increased the payoff from closer coordination of successive production stages to increase the precision with which the final products meet market specifications. Market-oriented firms allocate in response to prices and other terms of exchange generated in part *external* to the firms. But when there are important complementarities or supplementarities between successive stages or where the price mechanism is not functioning efficiently, there may be gain through *internal* coordination of successive stages.

These changes require that a broader focus for finance research, to include problems of financing an interrelated set of production stages, whether market-collected or internalized within firms. Indeed, finance plays an important role in interstage and interfirm coordination. Depending upon the circumstances and point of view, it can be either the means for accomplishing coordination or an important by-product of the process. For example, before a vegetable producer can finance his operation, he usually must secure a marketing contract and establish his capacity to produce to the quality, quantity, price and other significant specifications of that contract.

Where important interstage complementarities exist, coordinating such stages within a single firm through vertical integration tends to increase the financing available to the total enterprise. Not only do small firms often find that through integration they have access to a greater volume of credit from new sources, frequently the total volume of financing available to the integrated industry is greater than was the total financing to all the segments prior to integration.

Structural Consequences for Agriculture

The changing role of finance is generating important structural changes in agriculture, some of which are implicit in our discussion of interstage coordination. We will briefly discuss two among many additional consequences.

If the traditional owner-operator pattern is to continue to dominate agriculture, *growth* and *economic viability* will need to replace a *deft-free balance sheet* in the hierarchy of goals of farm operators [10]. Even so, the separation of ownership and management appears to be an inevitable structureal condition of a capital-using agriculture and is proceeding at two different focal points.

---

[5] Following Mighell and Jones [13], we define an economic stage as an operating process that starts with marketable inputs and ends with salable products.

First, with *financial* assets: Money capital is supplied by stockholders in exchange for shares of the undifferentiated assets and residual profits of the business, while management and labor is provided professionally in exchange for salaries and wages (including retirement programs and other fringe employee benefits) [11]. The large corporation provides both the intellectual and mechanical framework for tapping the money market for equity capital and is then in a stronger position to secure more liberal nonequity financing than is the typical farmer.

Second, with *non-financial* assets: Individuals or corporations might make particular physical resources available to the farm business in exchange for money claims against the business. There is no reason why the firm owning farm resources and the farm production firm need be the same or even have the same legal or structural form. Leasing, custom hiring of services, or the financing of inputs by suppliers and marketing firms are alternatives to incorporation as a means of providing control over outside capital to farmers. Efforts toward improving these markets might reduce some of the attractions which currently seem inviting to corporations.

Such structural implications suggest significant changes in the market behavior of agricultural producers. Will they become more or less responsive to price in the supply of farm products and demand for farm inputs? The answer will depend not only on changes in interstage coordination, but in the manner in which financial aspects are incorporated with those of production and marketing in firm equilibria. In turn, this depends upon expectations held by producers on behavior of lenders and lessors accessible to them, and upon the internal business structure of the firm.

Policy Issues in Finance

The expanding role of capital in agricultural production and marketing increases the impact of both private and public financing decisions on such important policy issues as (1) resource control and the organizational structure of agriculture; (2) resource efficiency; and (3) farm prices, income distribution and poverty in agriculture [6]. Whether the growth through financial aggressiveness generates diseconomies in a welfare sense must be the subject of another paper

Resource control and organizational structure

If our earlier discussion of the "structural consequences" is relevant and not too wide of the mark, relative skills in financial management and attitudes toward the use of debt are crucial in determining firm growth. In the long run, the factors affecting firm growth will largely determine the organizational structure of agriculture. It is an exceptional farmer who can match the corporation in terms of financial management competence. Responsive financial intermediaries can help. But they have limited capacity relative to the magnitude of the task.

If a national policy objective is to maintain family farming in a dominant role, resources allocated to research and education in financial management likely will have a favorable payoff. In fact, it might be *the one* important area where the fruits of research and education might not work to the relative advantage of large corporations

Resource efficiency

We have already shown that the optimum combinations of resources and products when differences in financing costs are included will differ from optima based on the price ratios. We suggest that the relevant optimum, in terms of social optimizing, will include all differences in the real cost of financing, including risk. Deviations from this optimum can be caused by (1) lender attitudes based on a lack of knowledge or personal preference which leads to responses not supported by differences in the real cost of financing, and (2) erroneous farmer expectations of lender response. Such simple matters as helping lenders understand the nature and details of the farm businesses in the community and helping farmers sense and understand lenders' attitudes might well shift resource use toward greater efficiency.

The heavy reliance on liberal financing to promote sales of some farm inputs might lead to a misallocation of resources. Farmers might subsitute a more costly input for a cheaper (but equally effective) one solely because the terms of financing are much more favorable. As a consequence, farmers may be able to obtain more (and possibly cheaper) financing for these inputs than for lower priced substitute inputs.

Programs that reduce income uncertainty from particular products (whether initiated by public groups, such as the price support program, or by private groups, such as a futures market in fed cattle) tend to increase the financing available for these products relative to others. Recent shifts in the fresh vegetable industry toward broad geographic diversification to spread weather and price risks are generating favorable lender response.

Farm prices, income distribution, and poverty

Increased stress on finance to achieve efficiency goals likely would speed up trends toward larger scale agriculture and the elimination of small scale family farm enterprises. Yet it cannot be taken as certain that size always is positively associated with socially relevant efficiency [7]. In any event, conflicts between goals of efficiency and such other expressed goals as rural stability and an egalitarian distribution of farm income must be resolved largely outside economics.

Poverty in agriculture arises from too few resources and/or inefficiency in the use of available resources. Farm credit programs can help resolve farm poverty problems only when they can materially help correct one or both problems. From his study of the Farmers Home Administration, Herr [9] concluded that for the 825,000 older farmers with chronically low incomes, production and investment credit would be of little value. But for those younger farmers with management potential, liberal supervised credit might have a significant payoff to general welfare. Credit generally is a very costly way to make permanent income transfers.

National Labor Relations Legislation: Possible Impact on American Agriculture

JOSEPH D. COFFEY

FARM workers and their employers are specifically excluded from the privileges and duties of the National Labor Relations Act (NLRA). This excludes farm workers from the right to organize and bargain collectively and their employers from protection against illegal strikes and secondary boycotts [8]. Several bills are now (August 1969) pending in Congress that would modify the present exclusions. Observers of farm labor legislation intimate that significant legislative changes are not likely in this congressional session. However, it is generally acknowledged that most of the major provisions of NLRA will be extended to hired agricultural workers within the next year or two. Final legislative form will depend largely on the relative influence and strengths of the opposing parties on the central issues of strikes at harvest time, union recognition, secondary boycotts, voter eligibility, and compulsory bargaining.

That agriculture has not been covered by NLRA does not necessarily mean that the agricultural sector has been unaffected by NLRA coverage of other sectors through its effect on off-farm job opportunities of agricultural workers. Space precludes an examination of such secondary effects, as well as an examination of the nature and functioning of the hired farm labor market. However, these two topics have been discussed elsewhere [1, 6, 9, 10, 15].

This paper focuses on the probable incidence of the costs and benefits within the agricultural sector of extending NLRA coverage to farm workers and their employers. The costs and benefits of NLRA will not necessarily be equally distributed geographically, sectorally, functionally, or personally. Furthermore, the initial recipients of the costs and benefits may lose or "relinquish" [11, p. 88] them to others as time passes. This is not to say, however, that NLRA legislation is necessarily a zero-sum game where the opponents vie for a bigger slice of a fixed static pie. Indeed, the second section of this paper concentrates on the more dynamic positive sum gains of NLRA.

Influence of Unionism on Wages

Influence of unionism in non-agriculture

Lewis [5, p. 543] concludes, after reviewing empirical findings based on 21 recent studies of unionism and wage differentials in the United

---

JOSEPH D. COFFEY *with the Planning and Programming Staff, U.S. Department of Agriculture.*

States, that the ". . . effects of unionism on the relative wages of union workers tended to be greatest during periods of rapid deflation of the general price level and lowest during times of unexpectedly rapid inflation. . . ." This variability of effects of unionization over time is usually attributed to wage rigidity. The influence of unionism on wages tends to be accounted for more by the negative correlation of wages with the rate of inflation than by positive correlation of wages with unemployment rates.

The industries in which unionism had the greatest effects on relative wage rates tended to be those with high relative wages and with a high proportion of union workers. Lewis estimates the effect of unionism on the average wage of all union workers, relative to the average wage of all non-union workers as:

1932 (rapid downturn of depression)	25 percent
1939 (depression recovery and pre-World War II)	10–20 percent
1945–48 (war period rapid inflation)	0 percent
1957–58 (recessionary period, low inflation)	10–15 percent

Lewis's summary estimates are not ideally suited for examining the possible impact of unionism in agriculture, as they are based on aggregate data and pertain to non-agricultural industries. Thus, we must be cautious in drawing implications from them for unionism in agriculture. Since agriculture is not a high wage industry and since the unionized proportion of agricultural workers is apt to be low, I anticipate that unionism of farm workers would result in lower relative wage effects than it has had in the industries which Lewis reviewed. This, of course, is not to say that wages of hired farm workers, whether unionized or not, will not increase substantially in the future. Indeed, even though there has been no significant unionism, since 1965 average hourly earnings in agriculture increased slightly relative to manufacturing [15]. Still, average hourly earnings in agriculture are presently less than half those in manufacturing.

Derived demand for hired farm labor

The (static) factors that contribute to the variations in the effects of unionism on wages in the short and intermediate time periods (roughly 1 to 10 years) can be identified and analyzed by the derived demand theory for labor. Assuming that (a) the production function for aggregate agricultural output is linear and homogeneous, and (b) that the two factors of production—labor and non-labor (hereafter "capital")—are used so that their marginal value products equal their prices,[1] the elasticity of derived demand for labor in equilibrium is [3, pp. 241–6]:

---

[1] The restrictiveness of these assumptions is tempered somewhat by the fact that the results are being used for short-run analysis. The limitations and omissions for long-run analysis are discussed in the next section. Nevertheless, even in the short

$$\lambda = \frac{da}{dp_a}\,\frac{Pa}{a} = \frac{\sigma(n + e) + ke\,(n - \sigma)}{(n + e) - k\,(n - \sigma)} \tag{1}$$

where σ = elasticity of substitution between capital and labor; n = price elasticity of demand for agricultural output; e = elasticity of supply of capital; k = share of output receipts going to labor; Pa = wage rate; and a = labor input.

Derived demand theory (equation 1) indicates that the elasticity of employment with respect to the wage rate (λ) depends upon the elasticity of substitution of capital for labor (σ), the elasticity of demand for agricultural output (n), the elasticity of supply of capital (e), and the relative share of labor (k). More precisely, in equilibrium the percentage decrease in labor employed corresponding to a one percent increase in the wage rate will be lower; i.e., the derived demand for labor will be more inelastic [3, p. 242]: (1) the less readily capital substitutes for labor; (2) the smaller the share of labor costs (provided $-n<\sigma$);[2] (3) the less elastic the supply of capital; and (4) the less elastic is the demand for agricultural output.

The rough calculations of λ in Table 1 suggest an elasticity of about -0.2 in the short run of 1 to 2 years and about -1 to -2 for a period of 5 to 10 years.[3] This means that if unionism results in wage increases of (say) 10 percent, employment of hired farm labor would be expected

Table 1. Elasticity of derived demand for labor (λ) for alternative demand elasticities (n), labor share (k), and elasticity of substitution (σ)[a]

Labor share (k)	Demand elasticity (n)	Elasticity of substitution (σ)		
		$\sigma=0$	$\sigma=1$	$\sigma=2$
$k=0.1$	$-n=0.25$	− .02	−0.9	−1.8
	$-n=1.00$	−0.10	−1.0	−1.9
$k=0.3$	$-n=0.25$	−0.07	−0.6	−1.0
	$-n=1.00$	−0.30	−1.0	−1.7

[a] Based on equation (1) with $e=10$.

---

run, to the extent that the production function is not linear and homogeneous and the market is not in equilibrium, the estimates based on equation (1) are subject to error. An alternative would be to use Tolley and Smidt's [12] model, but it was deemed to be too cumbersome for the purposes of this paper.

[2] In agriculture $-n$ is probably less than σ.

[3] The short run (1 to 2 years) and intermediate run (5 to 10 years), for purposes of this study, correspond respectively to the low and high values of $-n$ and σ.

to decrease by 2 percent in the short run and 10 to 20 percent over a longer period of time, *ceteris paribus.*

Extent of unionization

The influence of unionism on labor costs and employment depends upon the extent to which unionism occurs and (indirectly) upon the extent to which employers increase wages and improve working conditions to avoid unionization. Varden Fuller [2] identifies the following as forces that appear to favor the growth of unionization and collective bargaining in agriculture: (a) vertical integration; (b) more active and sympathetic public interest based on civil rights, minority groups, and related causes; and (c) extension of NLRA. However, Fuller observes that no sudden and sweeping wave of farm labor unionization is in prospect because of the following factors that tend to constrain it: (a) farm employment will continue to be predominately in small-scale, broadly scattered units; (b) seasonal workers are not generally responsive to unionization appeals (e.g., only 8 percent of farm workers in California in 1964 worked only for one employer and only in agriculture [2, p. 431]; (c) high cost of organization of farm workers; and (d) administrative and legal frictions under NLRA coverage with respect to bargaining agents and eligibility of voters.

I concur with Fuller's assessment. The lack of NLRA coverage has sharply constrained farm worker unionism. But the extension of coverage to farm workers does not necessarily mean that widespread unionism will occur. Indeed, it's an open secret that some major union officials have been less than completely enthusiastic, optimistic, and aggressive on farm worker unionization issues. Their stance, however, has apparently been emboldened significantly in the past year as they have increased their commitments of time, energy, money, and prestige to unionization of farm workers. This may quicken the passage of legislation and the spread of unionism.

The extent of unionism in agriculture will vary considerably among regions, farm sizes, crops, tasks, and type of worker. In certain areas, for example, the grape, fruit, and vegetable areas in California, a high proportion of hired farm workers might become unionized. In the Corn Belt, Great Plains, and South, farm worker unions are not apt to become important. Seasonal workers such as students and housewives are not apt to join or be interested in unions.

An upper limit estimate of the extent of unionism in agriculture would be the share of farm workers who might become eligible under the NLRA if and when it is extended to agriculture. The $50,000+ value of farm sales is the coverage criterion most likely to be adopted since that is the one that applies under present NLRA provisions for agriculturally related industries. (Sales criteria for coverage of certain other industries are much higher.) If the $50,000+ criterion were adopted, about 100,000 farms, 565,000 hired workers, and $20 billion of farm sales would be eligible for coverage (Table 2). The other possible criteria would have about one-half this level of coverage.

Earnings and labor cost impact

Unionization will probably occur first on the larger farms (500 or more man-days of labor in the peak quarter) that are presently covered by the minimum wage provisions of the Fair Labor Standards Act. There are striking contrasts between these covered farms and non-covered farms [15]. For example, from May 1967 to May 1968, hourly wages on covered farms increased 16 percent or double the 8 percent increase on non-covered farms [15]. These data, however, are single week observations and thus must be interpreted cautiously.

Table 2. Estimates of unionization coverage eligibility in agriculture for four criteria

	Farms employing one or more workers[a]				All farms[b]	
	Farms		Hired workers		Value of farm sales	
	Number	Percent of total	Number	Percent of total	Sales	Percent of total
	thousand		*thousand*		*billion dollars*	
Total	1,317	100	1,162	100	46	100
Sales:						
$ 50,000+	100	8	565	49	20	43
$100,000+	30	2	400	34	12	26
Man-days in peak quarter:						
500+	30	2	523	45	12	26
Wage bill:						
$10,000+	49	4	600	52	12	26

[a] Based upon [15].
[b] Based upon [14].

The alternative values of λ and average union/non-union relative wage effect can be used to estimate the possible impact of unionism on employment, earnings and labor costs (Table 3). The calculations in Table 3 suggest that: (a) employment would decrease by 0 to 5 percent in the short run and 10 to 15 percent in the longer run, and (b) weekly labor costs (earnings per worker times number of workers) in the short run would be 5 to 12 percent higher and in the longer run 0 to 20 percent lower than otherwise, *ceteris paribus.* The stable or decreased labor costs are due, of course, to the elastic value of λ.

A 5–12 percent increase in labor costs will not have a very large impact on total costs of production. For example, large commercial farms ($100,000+) had sales in 1964 of about $8.1 billion and hired labor expenditures of about $1.1 billion. If all of these farms were unionized, short-run labor costs would increase by $55 to $132 million, or 0.7 to 1.6 percent of total sales. However, on certain large commercial farms (tobacco, vegetables, and fruits and nuts) hired labor expenditures are about a third of farm sales, and the impact on total production costs would accordingly be greater.

Table 3. Estimated earnings and labor costs for alternative levels of influence of unionism on wages and derived demand elasticities for labor

Item	$\lambda = -.2$		$\lambda = -1.0$		$\lambda = -2.0$	
	Wage increase of unionism					
	5%	15%	5%	15%	5%	15%
	Percent change					
Number of hired laborers	−1	− 3	−5	−15	−10	−30
Hourly cash earnings	+5	+15	+5	+15	+ 5	+15
Weekly labor costs[a]	+4	+12	0	0	− 5	−15

[a] Example of computation: If unions increase wages by 5 percent and $\lambda = -.2$, number of workers will decrease by (5)(.2) = 1 percent and weekly labor costs will increase by 5 percent − 1 percent = 4 percent. Earnings per worker will increase the same percentage as wages, assuming hours per worker remain unchanged.

In addition to the likely effects on wages and employment, unionism may affect product mixes and factor combinations. I have not estimated the product mix and factor combination effects. In general, one would expect that there would be an accelerated shift to less labor intensive crops and more mechanization. The costs of producing crops such as strawberries and fruits, which are not presently nor soon likely to become mechanically harvested, will increase relative to crops such as tomatoes, cotton, and field crops, which are machine harvested. Production of those crops that have increased costs will tend to decrease, while their market prices will tend to rise and/or net imports (exports) to increase (decrease).

The likely short- and intermediate-run impacts of NLRA would be an increase in direct labor costs (money wages) and a reduction in employment. The impact of unionism might be substantial for employers and hired farm workers in certain regions, but the effects at the national level will likely be inconsequential in terms of labor costs and employment.

Longer-Run and Dynamic Productivity Impacts

The previous section has treated the likely shorter-run impacts of

NLRA in a largely static equilibrium framework. We now consider some of the likely longer-range and dynamic impacts of NLRA—especially those pertaining to labor productivity. Unfortunately, apparently no reliable nor conclusive empirical evidence is available which could be used to examine more adequately the longer-range and dynamic impacts. Thus, although this section will be even more speculative than the previous one, it is in my view of equal importance in assessing the possible impacts of NLRA.

Unions supply many services in addition to providing representatives for one side of the bargaining table. The NLRA extension may decrease the employers' labor recruitment and negotiation costs, reduce labor turnover and disruptions, encourage worker training programs, create pension, retirement and group health programs, etc. These are potentially significant benefits for the employers, as the unions may provide these services more efficiently than the individual employer. Furthermore, to the extent that turnover, reduced seasonality, training, and retirement programs result, the burden on those paying the welfare costs of the workers will be reduced. These factors may contribute to increased labor productivity and reduced labor costs.

Leibenstein [4, p. 62] has observed: "The extent to which labor is maintained will determine to some degree the amount of effort (or units of work) that will be forthcoming. The amount of work that the representative laborer can be expected to perform depends on his energy level, his health, his vitality, etc., which in turn depend on his consumption level (which depends on income level) and, most directly, on the nutritive value of his food intake."

This interesting possibility that a worker's productivity increases with his income and *vice versa* is often overlooked. Workers are typically viewed and analyzed within the same (static) theoretical framework as are other inputs. This is a fundamental misconception, as it overlooks that increased earnings may increase productivity by (1) acting as an incentive for workers to improve work efficiency; (2) attracting more productive and more regular workers, and (3) enabling and stimulating workers to make investments in themselves and their children's health, education, nutrition, etc. If we restrict our analysis of increased wages to the short-run static effects on costs of production discussed in the previous section, we inevitably will arrive at the conclusion—overt or covert—that increased wages may be good for the individual receiving them but is bad for those that pay them.

It might be objected that, although earnings may affect the worker's productivity, the increased labor costs have to be paid by someone. Therefore, those that pay the increased labor costs must reduce investments in themselves. Thus, it is allegedly "robbing Peter to pay Paul."

This would be true if all low wage earners had sufficient income and incentive to invest in themselves or ready and equal access to public programs of education, health, housing, nutrition, manpower, collective bargaining, etc. That this is not the case for many hired farm workers, low income farmers and others, is well documented [9, 15].

A "cheap farm labor policy" has been fostered by public policies, some of which are being reversed, such as importation of foreign workers, exclusion from most labor and social welfare legislation, school closings during harvest, state recruitment agencies, discouragement of industrialization in rural areas, tying farm programs to land ownership rather than to labor input, low welfare payments, discontinuance of food assistance programs during harvest, use of inmates during harvest, etc. A cheap labor policy, as Hla Myint [7] has explained, perpetuates a "vicious circle" of low labor productivity and low labor earnings.

This perpetuation does not necessarily follow the pattern in which the son is doomed to inherit his father's poverty Downward intergenerational occupational mobility rather than "inheritance of poverty" is the main route to farm wagework [2, p. 433]. As Fuller [2, p. 434] observes, "people have not become poor from working in agriculture; they have become agricultural workers because they were already poor." Few seek or indeed have a career as full time regular hired farm laborers. For many, if not most, hired farm work is a temporary expedient and/or a last resort. Thus, many hired farm workers have low educational levels and low skills. Farm worker employers justify low wages by noting that they pay "the going rate" or "what they're worth." Thus, the vicious cycle of low wages which attract low productivity workers becomes firmly entrenched.

No quantitative "guesstimates" of the costs and benefits of these long-run dynamic labor productivity and efficiency relationships will be made. "Plausible values" for the needed parameters are unavailable, or at least I have not found any. Even the direction and qualitative attributes of the impacts are open to debate. For instance, the "backward bending supply curve of effort" thesis suggests quite a different set of impacts and implications than the forward sloping one. Even if we reject the backward sloping thesis and (correctly) accept the forward sloping thesis, no reliable quantitative measures of impacts appear feasible at this time. As tentative hypotheses, I predict that the likely long-run dynamic contributions of NLRA extension would include: (1) more orderly, stable, and formal employer-employee relationships with less disruptive and potentially dangerous conflicts; (2) upgrading of productivity and occupational status of farm work; (3) improved employment conditions and incomes of farm workers; (4) reduced labor supply uncertainties; (5) reduced wage differentials; (6) new institutional and/or technological means of coping with seasonal peak labor demands; and (7) increased competition among farmers for workers. These contributions will not be without costs, and innovative proposals will be needed to assure that the optimal benefits are achieved. Nevertheless, the likely impact of NLRA extension does not appear as unpalatable or inimical to employers' interests as short-run static analysis suggests.

Summary and Conclusions

The resolution of all the labor and poverty problems of U.S. agriculture does not rest on the passage or defeat of the extension of NLRA to farm workers. To view the NLRA as either a threat or a salvation is to ignore many of the other structural and social changes that are occurring. From the short-run static point of view, the impact of the NLRA would probably be to increase slightly total labor costs and, to a somewhat greater extent, earnings of covered farm workers above what they would be otherwise. The aggregate impact at the national level is likely to be quite small. Most workers will support the extension of NLRA and most farmers will oppose it. The long-run dynamic implications are less tractable but nevertheless potentially more significant. The potentially beneficial and "positive sum game" impact of NLRA extension to agriculture is its contribution to breaking the vicious circle of low wages which attract low productivity workers and *vice versa.*

NLRA should not be viewed as a cure for rural poverty even though it may lead to increased food prices, which in turn might serve as a partial umbrella for small self-employed farmers. Most rural poor are either aged, infirm, uneducated, or nonfarm workers—not hired farm workers who might qualify for coverage. Furthermore, increased hourly wages will be of little significance unless the number of hours of employment per year are increased and underemployment reduced. Underemployment, low skills, poor health, and inadequate education are problems that will require a broad-based national commitment to alleviate poverty, disease, and ignorance. This is not to imply that NLRA would not contribute to alleviating certain poverty-related and economic development problems. It is to emphasize that the problems cover a broader range of issues than the NLRA is designed to prevent and/or alleviate.

Those who believe that farm workers are paid their marginal value products and view unions as "market distorters" which violate Pareto marginal equilibrations of our perfectly competitive economy will be apprehensive about the extension of NLRA to farm workers. I, too, am apprehensive, but for different reasons. My apprehension is not that the NLRA will upset the equilibrium of our perfectly competitive economy, but that it will not be structured and implemented in such a way as to break the vicious circle, reduce the market imperfections, and improve the low worker skills and productivity that I believe already exist.

TOWARD BETTER UNDERGRADUATE TEACHING

CHAIRMAN: B. F. STANTON, CORNELL UNIVERSITY

Can Better Teaching Be Learned?

LAWRENCE BRADFORD

TEACHERS can develop and teaching can be improved if: (1) the teacher likes to teach, i.e., has a dedication; and (2) there is a favorable environment, including a renewal of emphasis on teaching vs. research.

Emphasis at universities for the past 8 to 10 years has been to disfavor either improvement in teaching or a desire to teach. Rewards and promotions have been made largely on the basis of published papers. Hence, the slogan "Publish or Perish." However the current demand by students on university campuses calls for a better grade of teaching. This demand will increase.

For most courses in undergraduate teaching of agricultural economics, I see little correlation between teaching and research. That is, there is a meager amount of information gained in current research projects daily useful in the content of the specific course. This is not to say that research in agricultural economics is not important. It is to say that when doing teaching, one should not be pulled away toward completing a research project. There is probably more correlation for good teaching between current extension activities and teaching.

On the other side of the equation are the personal desires of the teacher. He must first of all like people as opposed to things or innovations. He must develop enthusiasm for his subject and believe that it is important that students gain the information he has to impart. My former students comment more on my concern, my illustrations, and aside remarks than on their acquirement of the theoretical aspects of economics. In other words, humanism and application are essentials of good teaching.

Next, a word on work. The good teacher must work harder and longer hours than he expects of his students. He needs an hour for fresh and renewed preparation for daily presentations immediately before each class. Old lecture notes should be discarded. That is, he needs to have clearly in mind what he will present, a time schedule, a method of presentation, charts and illustration materials arranged, and assignments clearly prepared. Perhaps he will spend more of the class hour on assignments than on the lecture.

Now with regard to assignments of the practices, problems, papers, etc.,

---

LAWRENCE BRADFORD *is professor emeritus of agricultural economics at the University of Kentucky.*

students are to prepare. Ideally there should be some exercise for students to hand in each class period, or longer ones each week. Students do no more work than is required of them. In later years, your rewards will come largely from the useful and understandable work you help them to do. Let us constantly remind them that the term education derives from the Latin *educere,* which translated means lead out—not pour in. Writing things involves thinking, the basis of education.

Preparation of exercises to be submitted will require work months or weeks ahead of the class beginning. They will need to be revised from year to year.

Self evaluation is important. This can best be accomplished by having your students grade you on a number of items such as clarity of assignments, voice control in lecturing, fairness in grading, understanding of course objectives, usefulness of course content, and application of the items of economic theories.

May I suggest that you secure a copy of a bulletin of The American Association of Colleges for Teacher Education; namely, *Student Evaluation of Teaching and Learning!* It is an excellent and comprehensive guide for developing questionnaires for obtaining the help of your students in measuring your own performance.[1]

The teacher must formulate a specific set of objectives. The author has found the following list to constitute an inspiring basis for course content for the beginning three-credit course.

Specific objectives:

1. To acquire an understanding of the problems of agriculture as a whole, i.e., to learn about agriculture as the composite of farming with those institutions, businesses, and industries directly related to farming.
2. To measure the place and to find the importance of farming and agri-business in the national economy, i.e., its size, its contributions, and its influences.
3. To acquire some understanding of the economic principles that govern the actions of farmers and those who buy from farmers and sell to farmers.
4. To learn how to use principles to put the resources used in farming together so as to make profits.
5. To learn more precise meanings of some 200 economic terms used in agricultural literature.
6. To learn how to read, interpret, make and use some of the elementary tools, such as graphs, charts, and indices.

---

[1] Order from Edward C. Pomeroy, Executive Secretary, The American Association of Colleges for Teacher Education, 1201 16th Street, N.W., Washington, D.C. 20036. Price, 50 cents.

7. To refine some common statements and thinking about price and production problems, and to reduce them to generalization or principles.
8. To consider the part of governmental programs in farming.

General objectives:

1. To improve written and spoken English.
2. To gain practice in uses of the scientific processes.
3. To develop some confidence, particularly in the making of economic decisions.
4. To foster pride and assurance in rural living.

Now, a word on grading. Levels of grades largely reflect the level of teaching. Each student's grade indicates the quality of teaching the teacher has accomplished with that student. If the student flunks the course, the teacher flunked also. He failed to motivate, explain, assign, check, or something. Again, I have never been able to see why a teacher desires to flunk a given number of students or to argue over one-half a percentage point on a grade.

I have been impressed by the similarity of performances of the teachers who have been nominated for our undergraduate teacher awards over the past three years. A number of them have been given the Outstanding Teacher Award of their respective colleges. These men have generally:

1. Taught large numbers.
2. Motivated their students, i.e., made friends of them.
3. Counseled and visited with students outside of class.
4. Advised with student organizations.
5. Participated in teachers' conferences.
6. Written articles on teaching.
7. Participated in off-campus activities.

Finally, a word on the costs and rewards of teaching. As I pointed out, emphasis for the past 8 to 10 years has been on research. Many teachers thus suffer rank and monetary losses in advancement from heavy teaching loads. This will change and is largely a short-time cost. In the long run, most of you will be better remembered as teachers than as research workers. Teachers' lives live on in the lives of their students. Bulletin writers are generally little accredited outside their own department and rarely known outside their own profession. This is true even for the outstanding agricultural economists. Even you, I dare say, know Schultz, Schickle, Black, Taylor, and Warren, for example, more as men and as teachers than you do for the research projects they carried on or the bulletins they wrote. This is even more pronounced with regard to the citizens of your own state. Satisfactions from teaching increase at an increasing rate. Satisfaction and recognition are life's greatest awards.

Toward Better Undergraduate Teaching

G. T. Dowdy, Sr.

To begin, teaching may be defined as the stimulation of learning concomitantly with learning, which may be defined as an active process carried on through doing, reacting, and sometimes undergoing changes and the like; and for both of these to be effective, the learner must participate in his own learning-teaching situation, hence his own education.

Methods of teaching are our "tools," which we use systematically to stimulate the processes of learning. Therefore, methods must of necessity take into proper account the nature of learning and the nature of the learner. To be effective, experience indicates that methods must also recognize the desired outcomes of learners, and they must be considered with learners of differing backgrounds and of differing levels of maturity, etc. I hasten to add that the teacher must play the role of a counselor following classes in order to study and arrange for proper adjustment in his approach to any differences that may exist among students. At this point, it is necessary to bring into this presentation a few words concerning methods. Occasionally, one may consider or interpret techniques and devices as methods; however, these are only parts within methods. Therefore it is not surprising that considerable confusion exists in the teaching circle through misinterpretations of the meaning of the word "method."

The following list will serve to telescope the situation—some people refer to the following as methods: recitation, textbooks, individual, project, study, socialized, drill, group, and visual.

None of the above is a method; each is a subsidiary technique, a device, or part of a method [1, p. 866B].

Over time, advances in the complexity of learning, coupled with the rise of an intellectual tradition of tribal history, brought about the development of the first teaching methods. These involved demonstrations of skills to be performed plus enforcement of drill or practice. Initially, the use of deductive logic produced many erroneous beliefs because the original premise was predicated on many unrealistic assumptions. Yet, the deductive method is nonetheless a sound teaching method especially in specialized subjects with college students. The basic principle used in the deductive method involves generalization of a law or idea together with illustrations. Employing this method, the student is led to analyze the principle and examples and then to find new ones in his general field of study. It is expected that the student or learner will use conservatism relative to limitations.

G. T. Dowdy, Sr. *is professor and head of the division of agricultural economics at Tuskegee Institute.*

Another method that should be mentioned is the inductive method, which presents the means for the verification of hypotheses. The essence of this method may lie in the belief that knowing and learning started with the observation of the world around the students, who would scrutinize the facts and problems related to them; this would, in turn, entail the development of hypotheses to guide and perfect the search for any additional facts. Such a method of teaching urges students to observe and analyze certain phenomena in the world, which will permit comparisons over a series of specific instances, and finally to distill some worthwhile generalizations. While this is an ideal approach to teaching, some teachers still use means that pound facts into the student's head to be memorized and given back in recitation.

Perhaps the two most dominant general methods of teaching are (1) the assign-study-recite-test procedure, and (2) the unit approach. These are useful for differing purposes, with differing levels of the student's maturity and advancement. Each of these methods can at time be subjected to abuse; yet each is dynamic, and improvements appear regularly as time passes.

Obviously, there are a number of factors that will improve undergraduate teaching, provided that some can be supplied and perhaps others removed. It is the general opinion of many that perhaps the most significant factor relevant to our subject is the college's own commitment to "excellence" in undergraduate teaching and the extent of support it gives to the aggregate phases of the teaching. To name a few: the level of support to research in connection with teaching; teaching loads; rotation in teaching assignment with respect to periods (hours); teaching loads with respect to assignments for the same course but different sections contrasted with teaching loads for different courses; the extent of *teacher-student* involvement in design and preparation of the evaluative instruments; adequacy and accessibility to the library; physical teaching facilities, inclusive of modern classrooms that would at least be as adequate and well appointed as the classrooms students enjoyed in high school; reasonable supply of audio-visual and other teaching aids (i.e., charts, diagrams, exhibits, films, film strips, globes, maps, models, photographs, pictures, posters, radio, TV, samples, slides, and teaching assistants).

The second most important category would be the teacher himself. Undergraduate teaching cannot be improved unless we bring into the teaching circle teachers who are dedicated and have a strong desire to teach and, moreover, those who have a high level of enthusiasm, optimism, initiative, resourcefulness, some sympathy, good personal habits (for these serve as valuable examples), integrity. They must realize also that their responsibilities as teachers extend far beyond the classroom itself; and they must have the foresight to "size up" and "face up" to students' vary-

Better Teaching—Some Curricular Aspects

LESTER V. MANDERSCHEID

BETTER teaching can be approached in a variety of ways including creation of a better environment for learning, more careful attention to class preparation, examination techniques, changed motivations on the part of students and others. All are important, but I want to focus on another dimension—the dimension of what is to be learned.

In addition to all the other attributes of good teaching, it is clear that one of the teacher's major roles is guiding the studies of students under his direction. Before a curriculum can be evaluated, we need to assess our student audience and define our educational goals. I assume that our educational goals involve developing the student into an educated man and into an applied problem solver with special emphasis on the practical social science problems of individuals or groups either in agriculture or in rural areas.

The next two sections center on the changing nature of current and potential students in agricultural economics and the changing nature of agricultural economics departments. These changes will then be related to curricular implications and the need for our involvement in planning the total curriculum, not just the allocation of credit hours. If taken seriously, total curriculum development is not an easy task. But too often we take the easy way out—we merely divide the curriculum into areas by credits and assume that our students receive an integrated total education.

Changing Nature of Students

To properly evaluate our curriculum, we need to recognize how today's students differ from previous ones. We must consider both the students currently enrolling in agricultural economics and those we believe should be enrolling in agricultural economics. It is this often overlooked potential market that holds the promise for an increased demand for the services of agricultural economists in undergraduate education. There are four ways in which I believe our students differ markedly from those of a generation ago. These four ways can be classified as (1) fewer with a farm background, (2) fewer planning to live in rural areas, (3) a more sophisticated academic background, and (4) an increased awareness of societal problems. Now let us briefly consider each in turn.

It is well known that many agricultural colleges now find that a large and increasing percentage of their students were reared in medium size

---

LESTER V. MANDERSCHEID *is associate professor of agricultural economics at Michigan State University.*

cities or metropolitan areas. This phenomenon is common also to the non-land grant colleges where a large percentage of students in agriculture now enroll.

Coupled with the changing pattern of students' previous living areas is their plan for future locations. A large percentage of our graduates in agricultural economics, as well as in agriculture, now expect to spend their professional careers living in urban areas.

High schools have moved rapidly to improve not only their science but their total curriculum. This improvement has been accelerated by school consolidation. Furthermore, this is the age of television, which has provided students with a great deal of knowledge in spite of its "vast waste land of entertainment." These forces combine to more than offset the effects of a larger number of high school graduates going to college.

A fourth change in our students is their increased awareness of societal problems and their concern for helping to solve these problems. In part, this reflects the affluence of the mainstream of American society amidst poverty and prejudice. In part, it reflects concern about an unpopular war and the fact of three shooting wars involving the United States in the last 25 years. In part, it reflects the greater sophistication of students brought about by the instant communication of television, increased travel, and improved secondary schools.

Changing Role of Agricultural Economics Departments

Associated with the change in the nature of current and potential students is the changing nature of departments of agricultural economics. Many departments are now engaged in graduate education at the Ph.D. level and in some, probably too many, there has been a tendency to emphasize graduate education to the detriment of undergraduate education. This tendency manifests itself in several ways. One is the shift of faculty interest and attention from the undergraduate to the graduate student and from the "average" undergraduate to the potential Ph.D. student. Another more subtle aspect is molding of curricula at the undergraduate level in the direction of preparing students for Ph.D. programs. While this is a laudable goal for many undergraduates, there is a tendency to warp the curriculum for all students in this direction.

One should not overlook the growth in agricultural enrollment, including agricultural economics, in the non-land grant schools in the last 25 years. Many faculty at land grant institutions are surprised at this development and express amazement when they learn of students who choose the non-land grant schools in their state when "the land grant college of agriculture has so much greater prestige." Yet, many outstanding students are thriving on the attention paid undergraduates and their needs in some of the non-land grant schools.

Curricular Implications

In this section I will raise questions in four areas of curricular concern. These questions arise from the previous observations on the changing nature of students and departments and from my involvement in curriculum planning.

1. *Are we including the right science courses in our curriculum?* Scientific advance has been rapid during the last generation and a great deal of new information is made available each year. This new information should lead to revised content in the science courses, whatever the area of discussion. For example, in the biological science area, much of the recent information has been at the molecular or cellular level on the one hand, or at the ecological level on the other. Yet, the courses traditionally included in our curricula have focused on the organismic level. Should we continue to require courses heavily oriented toward the organismic approach or should we require courses at the molecular, cellular, or ecological level, or some new survey course that covers all levels, or should students be given a choice of level? Another dimension of science that merits concern is the philosophy of science or the method of science, which is quite often discussed in the required science courses as well as in courses in methodology in agricultural economics. I believe too many students are learning *the* scientific method and too few are learning the variety of accepted approaches to scientific research that are common today.

2. *What kinds of courses in agriculture are relevant for today's students?* Students from the city often are suspicious of required technical agriculture courses. These courses are perceived to be how-to-do-it courses rather than courses than emphasize principles of value in the several potential off-farm occupations. An urban-based student interested in development, either rural development in the United States or urban redevelopment or international development, views the courses quite differently than the farm-based potential farmer. The agricultural business student fears that the emphasis on marketing of farm products will be at the expense of his understanding the marketing of inputs or of processed products in an imperfectly competitive firm.

3. *Are the social science courses that we require relevant to the student's concerns and interests?* With students' greater sophistication and greater social awareness, do the required social sciences courses help them understand social science conflicts that are or will arise in society? Our students need to learn not only the economic but also the political, psychological, and social aspects of social science analysis. Further, they need to see these aspects as part of a system, not as isolated components to be treated independently.

4. *Do the required humanities courses develop in students an awareness*

of value formation and the resolution of value conflicts within a human society? Students are aware that many current and potential problems involve value conflicts, but they often find the required humanities courses seriously deficient with respect to how values have arisen, how values change, and how value conflicts are resolved. Indeed, many students and graduates find great difficulty in relating humanities courses to current societal problems, let alone the resolution of these problems.

Even though this is an incomplete list of curricular concerns, it is obvious that we in agricultural economics cannot resolve all of these questions by ourselves. Rather, we must engage in dialogue with the faculty who teach in the various areas.[1] They are subject to many of the same pressures that we are—the pressures to publish, to produce Ph.D. graduates, to keep up with the latest literature, and, faint though it may seem, to better teach undergraduates. But we cannot simply allocate "x" percent of our curriculum to a given area and then let the faculty in that area exclusively decide content.[2] A student's education is whole, not a sum of parts. It is our responsibility as undergraduate advisors and curriculum builders to insure that our majors receive a whole education by actively engaging in the development of the whole curriculum.

---

[1] A number of highly useful study papers and reports have been prepared under the auspices of and are available from the Commission on Education in Agriculture and Natural Resources, National Academy of Sciences, 2101 Constitution Avenue, Washington, D.C. 20418.

[2] Of course, this is a matter of degree. We should help specify general content but not all of the details.

Inter-University Collaboration in Undergraduate Teaching

V. James Rhodes

LAST winter I suggested to President Breimyer a session at this meeting for the teachers of a particular undergraduate course. The session was to be a mini-workshop on goals, course content, and teaching materials; its objective, a fruitful exchange of ideas and materials, including, perhaps, the stimulation of joint efforts to develop new materials. The infrequent AAEA workshops on teaching improvement appear to concentrate on philosophy, psychology, and techniques of teaching. The neglected area seems to be teaching materials for specific courses. Our president didn't buy that workshop idea; instead, he commissioned me to talk about it here today.

As I thought about a paper on this topic, I realized how little I knew about the extent to which there is such cooperation among teachers and their attitudes on such matters. It seemed likely that my ignorance was fairly general. So a survey was born.

Two-page questionnaires were sent to the agricultural economics departments of the 50 state universities to teachers of five undergraduate courses: Principles, Marketing, Farm Management, and Prices or Cooperatives. I received 119 replies.

Current Practice

Two out of three of these 119 teachers have exchanged or received teaching materials pertaining to their course from outside colleagues.

How has such sharing occurred? Much of it has occurred through correspondence or through visits to other departments. Apparently, very little of it took place at workshops, symposia, etc.—probably because so very, very few have been related to teaching materials. Sharing of materials occurs most often between acquaintances; for example, instructors exchange with their ex-students.

What kinds of teaching materials are exchanged? You won't be surprised that course outlines led the list with 51 percent of the mentions. A distant second was reading or reference lists, 12 percent.

There is an interesting discrepancy between the rather limited variety of materials exchanged and teachers' attitudes as to what can be usefully exchanged. All 119 teachers were asked to select from a list the kinds of materials they thought could be usefully shared. The course outline—

V. James Rhodes *is professor of agricultural economics at the University of Missouri.*

checked by 70 people—was the leading item. However, other items were listed very frequently. For example, only 15 people had actually exchanged reading or reference lists, but 49 of this larger group listed it as a useful exchange item. Problems and exercises were listed by 56 teachers, visual aids by 42, examinations by 32, and lecture notes by 29. In other words, teachers are saying there is a rich variety of materials to be exchanged—a potential that exceeds by several-fold the present usage!

Length of experience effect. To check the possible effect of length of experience, the teachers were divided into the "less" and "more experienced" groups on the basis of whether they had taught this particular course five or more times. "Experience" in this context refers to a particular course, although it is substantially related to longevity as a teacher. Sharing of materials was reported by about 78 percent of the more experienced, compared with 52 percent of the less experienced. These percentages should encourage the new Ph.D. who occasionally may labor under the fear that seeking of assistance indicates some deficiency of energy or intellect.

Is the new teacher or the more experienced likely to benefit most from the exchange of materials? The response was that the newer teacher may particularly benefit, but there definitely is no generation gap in this game. Many older teachers wrote eloquent comments to the effect that the experienced teacher needs the continual stimulation of new ideas and materials to keep his course relevant and alive. There is no thought that anything as complex and personal as a course outline or an examination can transfer in entirety from one person to another. The name of this game is stimulation.

What role, if any, should be played by AAEA in facilitating this sharing of teaching materials? Only 16 felt that AAEA did not have a role. However, 59 people suggested a clearinghouse role for AAEA, 36 mentioned the sponsorship of workshops or seminars; and 16 suggested special efforts at our annual meeting, including special sessions on particular courses, exhibits of teaching materials, etc. For example, one teacher suggested an afternoon session on teaching of some particular course, with the price of admission being copies of your own teaching materials.

Let's examine further the two most popular suggestions: (1) that AAEA provide a clearinghouse, and (2) that it sponsor special workshops or seminars. The clearinghouse idea seems to mean various things, including:

(1) a published list of who teaches what and where; a modification is a published list of teachers and the kinds of materials they have volunteered to share;

(2) a central file of teaching materials, with copies available for a fee;

(3) an annual published summary of course references and subject areas covered in particular courses;[1]
(4) national committees to collect, pool, and disseminate materials.

Participation in any clearinghouse scheme should be entirely voluntary, of course.

We asked: "Would you be interested in participating in a workshop session devoted to the objectives, content, and teaching materials of your course?" Eight of every 10 said "yes", one said "maybe", and one said "no". About 3 out of 10 teachers had attended one or more of the AAEA symposia on undergraduate teaching such as the one at Virginia Polytechnic Institute in 1966.

Summary

Let me recap and editorialize. Teachers are interested in sharing materials, and this interest is as genuine for the veteran as for the new teacher. Two-thirds of the teachers have substantiated such interest by already exchanging materials relating to a course they are now teaching. However, the potential has not nearly been reached as to the number of teachers exchanging and especially as to the range and variety of materials exchanged. Group cooperation could facilitate the development of new teaching aids—visuals, film loops, programmed learning texts, etc.

Most teachers believe that AAEA should play a facilitating role. First priorities go to workshops geared to course content and to a clearinghouse approach. When 9 out of 10 teachers are interested in such workshop sessions, I think that is a pretty clear mandate. The clearinghouse approach can perform a function complementary to the workshop approach.

The variety of clearinghouse suggestions represent various stages of possible development. I suspect most of us would settle for an elementary beginning that has the potential to grow. To that end, I'm volunteering my services (really my secretary's) for the next year for a pilot operation of an elementary clearinghouse. I propose to provide a who, what, where list of volunteer participants. About March 1, 1970, I'll send out a list of those teaching a particular course who are willing to exchange materials, and the kinds of materials. The only way to receive the list is to volunteer before February 15 to exchange such materials. I will not solicit volunteers. I won't reproduce or transmit materials.

This is a one-year commitment. If there is significant response I will carry the story to the AAEA officers and ask them to adopt our baby. I hope that I'm not thought to be presumptuous in my volunteering. I appreciate, on the one hand, the slowness and caution with which the association must move, and, on the other hand, I believe that you teachers have said in this survey that you want to move.

---

[1] ODE, the Honor Society in Economics, does something similar. In their journal, *The American Economist*, selected reference lists and reading assignments of a few leading teachers are published.

Teaching can be improved. This exchange is one way it can be improved. Let's do it.

EXPERIENCES IN RURAL ECONOMIC DEVELOPMENT

CHAIRMAN: HENRY J. MEENAN, UNIVERSITY OF ARKANSAS

Problems that Persist in the Great Plains*

JOHN MUEHLBEIER

THE Great Plains is a vast region that extends from Canada nearly to Mexico. Its western boundary is formed by the Rockies. No clear demarcation exists for the eastern boundary, which is a wide transition zone extending from eastern North Dakota south into Texas [13, pp. 23–42].

The region is characterized by variable precipitation, extremes of temperature, a complex pattern of soils, a short growing season in the north, high evaporation in the south, high wind velocities, and high drought frequencies.

The average rainfall in the transition zone is near the critical limit for the production of crops. In many years, crops are good but in those years when rainfall is a little below average, or not very timely, crops fail. In the more humid region to the east, this is much less of a problem and in the arid region to the west, no problem at all.

The region is sparsely populated and largely agricultural. It produces much of the nation's wheat and range livestock.

Institutional Adjustments

The nation is currently much concerned about the social cost of space resulting from the extreme concentration of population in large cities [6, pp. 1–26]. In contrast, the Plains has long been concerned about the social cost of space resulting not only from sparse but also declining population.

Adaptation of governmental services

Nearing 40 years ago, Walter Prescott Webb [19] contrasted the settlement of the Plains with regions to the east by saying that an institutional

---

* Published with the approval of the director as Nebraska Agr. Exp. Sta. Journal Series Paper No. 2664. The views expressed are the author's and may or may not be those of the Great Plains Agricultural Council, the Economic Research Service, or the Department of Agricultural Economics of the University of Nebraska.

JOHN MUEHLBEIER *is secretary of the Great Plains Agricultural Council, agricultural administrator of the Economic Research Service, USDA, and professor of agricultural economics at the University of Nebraska.*

"fault" exists, somewhat comparable to a geological fault, running from Texas to the Dakotas. He wrote that "practically every institution that was carried across it, was broken . . . or else greatly altered" [19, p. 8]. For example, the various local governmental units, school districts, road systems, health services, and other institutions brought into the Plains were poorly adapted to the region. Adjustments have been made but much remains to be done [7].

The main problems with reference to local governmental units and schools are (1) high cost per capita, (2) low quality of service, and (3) burdensome taxes. For example, where the national average is more than 1200 persons per governmental unit, the average in some states in the Plains is less than 150 persons. Many of these units have neither the population nor tax base to support the necessary services [10, p. 29].

Health planning

Similarly, health planning in the Plains is also made difficult by sparse and declining population. The main problems in this field have been, and still are, providing (1) health personnel, (2) quality care, (3) financial support, and (4) health facilities. Much remains to be done in this field, particularly in providing and in raising the quality of care [4].

The organization of services and facilities so that good medical care is available in the Plains is a challenge. This includes provision for emergency care where distance and time are critical factors. It involves an upgrading of hospitals, particularly strategically located smaller hospitals, and the development of liaison among all hospitals.

Development of service centers

The Plains is a region of many small towns, some of which are declining still further because of loss of population from the region. For example, in one state less than 10 percent of the towns with a population of 2500 or less were found to be growing, and only those 15 towns with a population of more than 2500 persons were believed to have much of a future [18, p. 17].

The challenge is to plan for such towns or service centers as may be needed in the years ahead, considering both the public and private needs. This is a very difficult task. All of the present towns can not expect to grow and none can expect to provide the whole range of services needed. A plan for orderly adjustment and growth is needed [9, 316–345]

Some private firms have announced plans to develop new service centers. These firms may have the funds to build centers but whether they also have the necessary information remains to be seen. With technical help and adequate planning, the people already in the area should be able to provide the necessary services and thus avoid being replaced by new centers.

Lag in adjustments

Other needed adjustments could be discussed but perhaps the question should be raised as to why this lag in adjustment continues to exist.

For local leaders to work effectively in this field, they need relevant information, they need to understand the inter-relatedness of the several problems, and they need to take into account future needs of their community [2]. Local people seldom have much information or technical help. This accounts for the fact that we have cases where a costly school has been built following a consolidation of districts, only to be abandoned for lack of students within a few years.

In other words, the U.S. Department of Agriculture and land-grant universities have not conducted the research on these problems, nor carried out any extension programs comparable to those that helped farmers with production problems. Furthermore, institutional adjustments require community action and such cooperation is not easily attained. Institutional changes are more likely to involve controversy. Hence, the task of providing help becomes more difficult, but the price for not doing it comes high.

Farm Adjustment

From the early days of homesteading on a quarter section, later increased to a half section, and still later to a section but restricted to grazing land, the average size of farm has increased greatly. Physical characteristics of the region required adjustments in size and type of farm, as has technology in more recent years.

Strategies in operation

The Plains Region is a relatively "high risk" area for farming and ranching [8]. The economic problems faced by operators, in large part, stem from the limitation in choice of crops and from variations in the production of crops and grass. These, along with changes in price, result in variable farm income.

Studies have shown that variability of income can be reduced. Some of the strategies suggested to reduce variability include: (1) selection of enterprises that have low variability, such as forage crops and livestock, (2) combining of enterprises that have different patterns of year-to-year variability, (3) spatial diversification, (4) crop insurance, (5) irrigation, (6) flexibility in kind and number of livestock, (7) feed and financial reserves, and (8) adapted range and livestock management systems [1].

One thing should be noted, however; a reduction variability of income often results in a reduction in total income over a period of time. Increased stability comes at a cost. For example, studies of some proposed irrigation projects show that irrigation may reduce variability of production up to one-half but the return per dollar invested in irrigation would be less than the return per dollar under dryland conditions.

Periodically some operators still find themselves in distress as bad years follow the good. Accelerated Extension programs are needed on risk and uncertainty, in which problems, causes, and alternative strategies would be discussed.

Adaptations in size

In the process of enlargement, several small farms have often been combined into single operating units. Most of these are efficient family type farms. They have adjusted and are going concerns. The average farm income from farming compares favorably in the Plains with other regions but income from off-farm employment is lower. Many low income farms are found throughout the Plains with concentrations in certain areas in the eastern part of the Plains.

Many of the smaller operators have the ability to manage a farm and also have some resources at their command. They need a line of credit so they can operate more efficiently and grow. Some of the operators on small farms do not have much future in farming but, for one reason or another, may not be in position to prepare themselves for something better. It may well be in their interest to remain on the farm until retirement and this may also be in the public interest, even at some public cost.

There is still another low-income group however, where some change in policy seems desirable. These are younger individuals who show little promise in farming or who have few resources but who could be helped to prepare themselves for other employment. It would seem to be neither in their interest nor in the public interest to extend them credit for farming, and least of all, to give them priority over others who have some chance to make it.

For these individuals, or even others who wish to make a change, alternatives need to be provided, such as loans and grants for educational purposes and possibly other help. In place of being considered only for credit, or turned away with no help, the best alternative for them should be provided.

Land Use Adjustments

When land of relatively low productivity is kept in cultivation, crop failure, wind erosion, and economic distress often result. This is especially the case in the Plains because of a large acreage of poor cropland and a variable climate.

Reduction of crop failure and control of wind erosion

In the drier periods, such as in the mid-1950's, from 10 to 15 million acres were reported damaged by wind erosion in each of three years [17]. In addition, from 10 to 25 million acres were reported in condition to blow. From 1 to 5 million acres of crops were destroyed each year during that period. Although the dust storms were more awesome in the mid-1930's than in the mid-1950's, the acreage reported damaged was greater in the '50's.

Some land once farmed in the Plains was found, through bitter experience, to be unsuited for cultivation and has since been restored to grass. A considerable acreage of low-productivity land is still farmed, however. For example, in 1957, 15.4 million acres of Class IV land were reported as cropland compared with 20.5 million acres in 1967 [16]. Similarly, in 1957, 13.8 million acres of Class V-VII land were reported as cropland compared with 10.3 million acres in 1967.

In other words, Class IV cropland increased 5.1 million acres and Class V-VII decreased 3.5 million acres. To what extent Class V-VII cropland has been regrassed or simply reclassified is not known. What is relevant to this paper is that the total of Class IV and Class V-VII is almost the same today as 10 years ago, and 10.3 million acres of Class V-VII cropland remain. In view of the fact that soil scientists consider Class IV land close to marginal for crop purposes and Class V-VII unsuited for continued cultivation, the problem persists.

Facilitating regrassing

Beginning in the late 1930's, much discussion centered on the need for an incentive for regrassing greater than that provided by an annual payment offered by the Agricultural Conservation Program and widely used by farmers and ranchers. It was recognized that the establishment of grass involved considerable risk. To reduce the risk, a contract was discussed in which the operator would be assured, before he started conversion, of annual payments for a period of years [5].

At a Drought Conference called by the Department of Agriculture in 1954, a recommendation was developed that the Agricultural Conservation Program Service be authorized to make forward commitments with regard to cost sharing on establishment of permanent vegetative cover [14, p. 3].

The Department followed up on this recommendation and sought an amendment to Section 16 of the Soil Conservation and Domestic Allotment Act. The amendment proposed that the Secretary of Agriculture be authorized "to enter into contracts . . . with producers in the Great Plains . . . to make . . . changes in their cropping patterns and land uses . . . and to install the soil and water conservation measures needed under such changed systems" [11].

In the hearing on the proposed amendment before the Committee on Agriculture in 1956, the Department estimated that it would take $112 million out of a total authorization of $150 million, or 75 percent, to convert 10 million acres of cropland to grass; $30 million, or 20 percent, to reseed 6 million acres of rangeland; and $8 million, or 5 percent, for associated measures [12, p. 6 and 13].

The proposed amendment passed and the Department set up the Great Plains Conservation Program and named the Soil Conservation Service to administer the program.

The program has now been in operation about eight years. Have the goals been achieved that were set forth? Only in part.

The reports show that less than 15 percent of the funds have been used for regrassing, about 10 percent have been used for reseeding, and the remainder, or 75 percent, have been used for other conservation measures, particularly for terraces and reorganization of irrigation systems [15]. So far, fewer than one and a half million acres have been regrassed. The problem of farming low-productive land persists.

What is probably needed is a review and reorientation of all related Department programs, including research, extension, credit, crop insurance, acreage control or land retirement programs, conservation cost-sharing, technical aid, and particularly the Great Plains Conservation Program, to make sure that all contribute as much as possible toward control of erosion in problem areas and regrassing of land unsuited for continued cultivation wherever a concentration of such land exists.

Improvement in range-livestock management

In the Great Plains Region, nearly 200 million acres are used for range-livestock production, an important resource. The main problems of the range consist of relatively low productivity, poor range management practices, inadequate strategies for minimizing adverse effects of weather and markets and maximizing the returns in the good years, inadequately developed range-livestock management systems, and high investment in land per animal unit [3, p. 47]. Ranchers in the Plains will also face competition from those in other regions. Changes in farm programs could also affect them.

Research on range and livestock management problems seems limited, considering the vastness of the range and its potential. Extension programs are still more limited. A need exists for accelerated regional research projects, of an interdisciplinary nature, on improvement of the range, development of management strategies for survival and capital accumulation, and development of range and livestock management systems. Equally necessary are accelerated Extension programs in these same fields.

Water Resources

Water is a scarce resource in the Plains. Over much of the region the average annual runoff is less than 1 inch, although in the eastern part it is from 1 to 5 inches.

Of the rain that does fall in the Plains, more than two-thirds is lost by evaporation alone. Even a small reduction in evaporation would greatly add to the stability of production. This is especially important in the effective 20-inch rainfall zone.

Accelerated research on soil-water-plant relationships and on the adaptation of plants to climatic stress would result in reduction of crop loss and economic distress. The benefits would be region-wide.

Economic Development

The largely unplanned economic development of this nation, in which population and industry were permitted to concentrate in a relatively few large cities, has taken its toll. Those in the cities have such problems as congestion and pollution. The public bears the cost of such problems as urban renewal. The Plains has the problems associated with a declining population. To date, little has been done to assure that economic growth will take place where it is the most economic, taking into account both industry and public costs.

Local economic development is, of course, encouraged in various programs but the results are rather limited and rural areas continue to lose population for lack of jobs.

In their struggle to attract industry, smaller towns compete with each other by offering concessions they can ill afford to industry often well able to finance itself. Stronger national measures need to be considered if more balanced economic growth is to take place.

Administration of Programs

The grouping of states for the administration of national programs nearly always results in Plains states being grouped with some outside the region. As many as three or four administrative regions of a single agency of the Department of Agriculture may reach into the Plains. This is also the case in other major departments of government and with many committees organized by the states. When this takes place, attention is often diverted from the problems of the Plains. They may be overlooked or overshadowed.

Just recently, Federal regional councils were established by the President. Three of these reach into the Plains. These councils may serve their purpose. Plains people will need to be alert, however, to assure that Plains problems receive due consideration and are not over-shadowed.

In conclusion, as further progress is made in the alleviation of these problems, the economy of the Plains will become more stable and the well being of its people will be enhanced.

Rural Areas in an Urban Economy*

MONROE NEWMAN AND ELI P. MARCH

WHEN the Congress passed the Appalachian Regional Development Act in 1965, it established a new agency, provided it with a new set of operating instructions, and told it to work on a relatively old problem. That problem, of course, is the record of relatively low incomes, high unemployment and underemployment, out-migration, poor health, and inadequate education that have been generally characteristic of Appalachia—symptoms also characteristic of rural America. The approach of the Appalachian program to these problems, therefore, has significance for all rural areas of the country and, in fact, for all areas.

In the debates and discussions of recent years concerning "urban-rural balance," "rural renewal," and a national urban policy, one thread of agreement seems to exist—the intertwining of urban and rural problems. We simply cannot separate the solution of our urban and rural problems into separate compartments. The historic exodus from our rural areas has depleted their most valuable resource, their young people, who have too frequently been redundant and ill-equipped in their new urban environment. An approach to overcoming typically rural problems that holds even modest promise would be welcome in the effort to reduce problems of urban and rural areas to manageable proportions.

Another thread of agreement in the discussion of urban-rural policy, though less overtly stated, is that there is no possibility for a program to stimulate a "return to the land." For better or worse, we are an urban and urbanizing nation and national policy must both recognize this fact and, simultaneously, avoid confusing the term "urban" with "metropolitan." The former does not necessarily mean the latter, and wise public policy must capitalize on what both can offer.

There have been numerous attempted explanations of this urbanizing phenomenon. Some seek an explanation in a hierarchical structure of cities whose size and placement follow some regular pattern. Others seek it in agglomerative economies that confer pecuniary and non-pecuniary advantages. Still others seek it in an increasingly greater rate of invention and innovation as urban size increases. And there are those who seek the explanation in a higher degree of income elasticity of demand for services than for goods.

Candor requires that we admit that a preference for one of these expla-

nations over others may be more emotional than logical. Certainly, agreement and reconciliation among them have not been achieved, and public policy is therefore left with a conclusion with which it must reckon—we are an urban and urbanizing nation—without understanding fully why we are. Not fully knowing why may be a common problem in policy-making but it is, nevertheless, a troublesome one. It is in this unsettled realm of hypothesis that the Appalachian program was created and has existed. To understand the Appalachian program's possible significance for the national debate on these issues requires knowing more about the program itself.

The 1965 Act created a new institution, the Appalachian Regional Commission, consisting of the governors of the 13 States in the Region (who together hold half the voting power) and a representative of the President. The Commission is therefore a hybrid and so is its staff, who are neither Federal nor state employees. For the first time in our history, the Congress provided a mechanism that involved the state governments directly in decisions concerning the allocation of funds among themselves and among major purposes. By itself, this institutional innovation is worthy of study because it provides an operating alternative to both the existing Federal grant-in-aid system and to the bloc grant approach, both of which have vociferous detractors. In carrying out its obligations to the Region and the country, the Commission is guided by a policy prescription in Section 2 of the Act [2]. Investments under the Act are to "be concentrated in areas with significant potential for future growth, and where the expected return on public dollars invested will be the greatest."

To implement this prescription requires two basic types of decisions that under the Act only the states can make: (1) the determination within each state of areas with significant growth potential, and (2) the establishment of functional plans to capitalize on the potentials and overcome the deficiencies of these areas. Decisions like these are not easy to make, either technically or politically, but they have been made and are the basis on which public expenditures are made.

To assist the states in these decisions, the Commission accepted a staff paper containing the following definition of an area with significant growth potential [1, pp. 4–5].

> Generally, an area with significant potential for future growth will contain two geographical elements—a center or centers, and an associated hinterland.
>
> "By a center or centers is meant a complex consisting of one or more communities or places which, taken together, provide or are likely to provide a range of cultural, social, employment, trade and service functions for itself and its associated hinterland. Though a center may not be fully developed to provide all these functions, it should provide or potentially provide some elements of each and presently provide a sufficient range

> and magnitude of these functions to be readily identifiable as the logical location for service to people in the surrounding hinterland.
>
> Some of the key relationships or "linkages" that exist between centers and hinterlands include:
>
> 1. Commutation patterns
> 2. Wholesale trade services
> 3. Educational and cultural services
> 4. Professional services
> 5. Inter-firm and inter-industry trade
> 6. Governmental services
> 7. Natural resource and topographic considerations
> 8. Transportation networks.
>
> A hinterland may itself contain secondary service centers from which the population may be more efficiently provided certain services.. Whether a center falls into the primary or secondary category depends upon the range of services provided to the hinterland.
>
> A secondary center may be identified as an area of growth potential, but its proximity to the primary center and its position in that center's hinterland hinders its future growth, and therefore the range and magnitude of public investments to be made in it. The public investment program for a secondary center must be related to the program for the growth area as a whole.

This definition clearly reflects an urban, urbanizing pattern as the design of American economic development for the foreseeable future, and the one into which the Region must better adjust itself. At the same time, it avoids establishment of numerical standards of growth potential. In a region as large and diverse as Appalachia, consisting of all of West Virginia and parts of 12 other states, with a population of close to 19 million, and containing such diverse large cities as Pittsburgh (population, 600,000) Birmingham (population, 340,000), and Ashland, Kentucky (population, 31,000), it is impossible to establish workable uniform standards. Rather, within each state, relative standards must be applied, though always within the urban, urbanizing orientation.

Another distinguishing feature of this definition is the recognition it gives to the functional relationship between a center and its rural hinterland. The relationship is symbiotic—each serves and, in turn, is served by the other. There is no intent in Commission policy to contain public investments within the boundaries of the urban center. Policy guidelines repetitiously speak of investments to "serve" an area with growth potential, recognizing that such service may be best provided from outside the center but demonstrably serving it. These same guidelines also recognize exceptional cases, cases of rural populations so remote from a center that specific public services cannot be provided to them efficiently from those centers. These people still deserve and should be provided with at least the scale and diversity of services our consciences tell us all Americans should receive.

The Appalachian effort, therefore, is guided by a new type of institution that is attempting to meld a region with highly rural attributes into the American society. It is attempting to do so by capitalizing on that society's urban bent in two directions: first, to augment the Region's urban complement to make it more competitive with its national counterparts; second, to assist its people to contribute and prosper in this society wherever they may choose to live.

Of the many issues raised by the program, two have been selected for comment here—the evolving urban pattern of the Region compared with the Nation, and the implications of this for regional and national policy.

Appalachia's Urban Pattern

The basically rural character of Appalachia is best demonstrated by 1960 rural-urban population data. In that year, when the Nation was 69.9 percent urban and, therefore, 30.1 percent rural, Appalachia was 47.3 percent urban and 52.7 percent rural. The latter was typically rural, non-farm.

From 1960 to 1966, the U.S. population grew by 17.6 million, or almost 10 percent. Appalachia's population grew by only 538,000 or 3 percent. During this period, the Region experienced a net outmigration of 606,000, a rate of outmigration well below that of the 1950–1960 decade as a whole, but still substantial. A continuing net outmigration should not be surprising; in fact, its absence would be since in the 1950–1960 decade a net total of 2.2 million people left the Region.

In 1966, Appalachia had about 5 percent of the nation's metropolitan population but its metropolitan areas received slightly less than 1 percent of the nation's metropolitan growth since 1960. This, on its surface, would not appear to be a hopeful sign since the Region's future may well be tied in substantial part to adjusting to the national urban pattern. When the relative distribution of growth and the performance of the individual state portions in the Region are examined, however, the picture becomes somewhat less pessimistic and more explicable. These data are presented in Appendix Table 2.

The population changes from 1960 to 1966 by urban size class of counties[1] in the United States reflect the nation's urban-urbanizing pattern.

---

[1] For the purposes of data organization, counties are classified as follows:

Class	Definition
5	Metropolitan (included within SMSA)
4	Total urban population over 50,000
3	Total urban population 25,000 to 50,000
2	Total urban population 10,000 to 25,000
1	Total urban population 2,500 to 10,000
0	All rural

In the text, classes 0 and 1 are called rural and minor urban; 2, 3, and 4 are called moderately urban.

The only types of counties that lost population during this period were those that had less than 10,000 urban population. This pattern did not hold in Appalachia where counties of all levels of urbanization increased in population. For the United States as a whole, the total population change of 17.6 million was highly concentrated in metropolitan counties. In the Region, the total growth of 538,000 was distributed quite differently, as shown in Table 1.

Table 1. Distribution of population growth, 1960 to 1966

County type	United States	Appalachia
	percent	
5	90.5	29.4
4	3.9	5.3
3	5.4	15.6
2	1.4	24.7
1	−0.8	17.9
0	−0.4	7.1
Total	100.0	100.0

For the nation as a whole, slightly over 90 percent of the growth was in metropolitan counties. All the non-metropolitan counties with over 10,000 urban population grew by 10.7 percent. In Appalachia over 29 percent of the growth was metropolitan, over 40 percent was in moderately urban counties (10,000 to 50,000 urban), and 25 percent in rural and minor counties. Clearly, Appalachia's population is not distributing itself in a microcosm of the nation. In fact, it is showing rural and minor urban county population growth while its metropolitan counties show a rate of growth one-sixth that of the U.S. metropolitan rate of growth.

Since so much of the nation's population increment is concentrating in metropolitan areas, careful attention to the performance of those in the Region is warranted. Compared to the Region's total population growth of 2.9 percent, its metropolitan areas grew by 2.2 percent. However, there was considerable departure from this average metropolitan growth rate in the various state portions that contains SMSA counties (Table 2).

In relative terms, the range is from a loss of about 3 percent in West Virginia's SMSA counties to a gain of over 18 percent in Georgia's. The pattern of relative gains and losses is also interesting. Either losses or relatively small percentage gains typify Appalachian Ohio, Pennsylvania, and West Virginia with their older manufacturing cities. The growth performance is relatively better (though still below the national rate, except in Georgia) in Appalachian Alabama, Georgia, and North Carolina, with their more recent trends to manufacturing. Overall, there is tendency for

Table 2. **Population growth of Appalachia's SMSA counties, 1960-1966**

SMSA counties	Change in population numbers	Percent change in population
Alabama	103,881	9.3
Georgia	15,996	18.0
Kentucky	1,037	2.0
New York	14,737	5.7
North Carolina	35,594	11.8
Ohio	9,467	3.0
Pennsylvania	−54,142	−1.5
South Carolina	14,994	5.9
Tennessee	32,315	5.5
West Virginia	−18,335	−3.2
Appalachia	158,041	2.2
United States	15,885,832	13.3

metropolitanization to be relatively more effective in the southern part of the Region.

In absolute terms, the picture is generally the same but changes in emphasis arise because of the varying population sizes of the metropolitan areas of the states. The actual numerical changes are also shown in Table 2.

Though not the leader in relative growth, Alabama's Appalachian SMSA counties accounted for 66 percent of the Region's total SMSA increment. Adding North Carolina's increase to Alabama's accounts for 88 percent of the total net change. The absolute declines in Pennsylvania and West Virginia only serve to reinforce further the conclusion that Appalachia's metropolitanization is not only behind the national pace but is largely confined to Southern Appalachia.

Turning to the other extreme of the urban hierarchy, the rural and minor urbanized counties of Appalachia grew by 134,000. They accounted for 25 percent of the Region's population growth and added 2.8 percent to their own population.[2] On the national scene, these same categories of counties lost 211,000 people. (In other words, outside Appalachia, counties in these categories lost a total of 345,000 people.) Again, it is instructive to look at the Regional distribution of the absolute and relative gains (Table 3).

Compared with the United States, in relative terms, only West Virginia noticeably follows the pattern and, in that case, it is a reflection of a relatively large overall population decline. Of that state's total loss of 51,000, almost half occurred in counties whose urban population was between 2,500 and 10,000. The southern states of Georgia and North Carolina lead the relative growth ranking, but the pattern is mixed. Ohio and Maryland follow in rank order, and no clear north-south pattern exists.

---

[2] Rural counties grew by 2.2 percent; minor urban counties by 3.2 percent.

In absolute terms the picture is far clearer and the southern propensity for growth even more apparent. Of the net population growth in these counties of 134,163 for the entire Region, 116,380 was in the four southern states of Alabama, Georgia, North Carolina, and Tennessee (Table 3).

Table 3. Population Growth of Appalachia's rural and minor urban counties, 1960–1966

Rural and minor urban counties	Change in population numbers	Percent change in population
Alabama	20,813	5.6
Georgia	41,824	11.6
Kentucky	— 886	−0.1
Maryland	1,580	7.7
Mississippi	11,476	4.5
New York	9,679	6.7
North Carolina	32,021	7.8
Ohio	2,235	0.8
Pennsylvania	12,121	3.6
South Carolina	896	2.2
Tennessee	31,722	5.6
Virginia	2,651	1.0
West Virginia	— 29,940	−3.6
Appalachia	134,163	2.9
United States	−211,317	−0.8

Over 45 percent of the total Appalachian growth occurred in non-metropolitan counties whose urban populations totaled between 10,000 to over 50,000. On a national basis, these counties accounted for less than 11 percent of the growth. In Appalachia, more than half the growth in these counties (i.e., one-quarter of the regional total) took place in counties with between 10,000 and 25,000 urban. For the entire country, more than half the growth in these counties (about 5 percent of the total) took place in counties with between 25,000 and 50,000 urban. The relatively greater dominance of the less urbanized counties in Appalachia's growth is apparent.

The basic pattern of greater southern growth is also revealed. Of the net growth of 28,705 in the entire Region of class 4 counties' population, 34,353 of the pluses were in South Carolina and Tennessee; of the 132,899 net growth in the entire Region in class 2 counties' population, Alabama, Georgia, Mississippi, North Carolina, and Tennessee accounted for 102,888. There are surprises, however. In the class 2 counties, those in Ohio grew by 21,607 or 7.0 percent, a performance that would not be expected on the basis of either the national or regional pattern. An even greater surprise is in the distribution of the net growth of 84,012 in counties with a total urban population of 25,000 to 50,000. Though Alabama accounted for a net growth of 29,623 (which could have been expected), New York and Pennsylvania each experienced growth of over 16,000 in counties of this urban size class.

It is now time to take one more look at Appalachia's net outmigration of 606,000. Pennsylvania and West Virginia account for 393,000. Kentucky provided 76,000 and Ohio and Virginia provided another 58,000. Again a basic north-south pattern appears. With about 40 percent of its population, the Region's metropolitan counties contributed almost half of the outmigrants. With below a quarter of the Regional population, rural and minor urban areas contributed more than proportionately to the exodus. Though they too exported population, the moderately urban counties did relatively better.

The pattern of population growth that emerges can be summarized as follows:

1. Appalachia is growing less rapidly than the United States.
2. Appalachia's metropolitan areas are growing less rapidly than those of the rest of the country.
3. All other types of counties in the Region are growing more rapidly than their national counterparts.
4. By and large, in all classes of counties the southern part of the Region has had a better recent population record than the northern part.
5. Close to half of the Region's total growth has been in moderately urbanized counties.
6. These moderately urbanized counties are virtually the only ones showing growth in the northern part of the Region.

Implications for Policy

Within the rural-urban policy discussions of the last few years, there have been speculations about two separate but related subjects: (1) whether there exists within our economic society an acceptable alternative to metropolitanization, and (2) whether it is possible to deliver efficiently the range and quality of public and private services to rural people that more urban citizens receive The Appalachian data and experience are relevant to each of these.

A look at the income data in Appendix Table 2, along with the population change experience just described, provides some interesting insights. At least in one relatively depressed region, non-metropolitan but urban counties are showing relative vitality of population growth. Perhaps Appalachia's present pattern of urbanization is a way-station to metropolitanization, but it is also possible that we may be seeing a viable alternative pattern emerging in an area that was not metropolitanized in the years when technology and markets first seemed to require it. A first glance at the income data tends to deny this possibility, however. In every Appalachia state, the declining size classes of counties ranked by urban population are matched by declining per capita income with three exceptions—one reversal each in Pennsylvania and South Carolina and two in Tennessee. This is a pattern we would expect on the basis of national observation, and it suggests that the Region's metropolitan areas may be the final destination of a population in transition from rural life. As economists, we typically assume that income differentials are something of a predictor of the direction of movement and, assuredly, in Appalachia per capita incomes are higher the greater the degree of urbanization.

However, there is another way to measure income differences that may be more meaningful, i.e., the amount of absolute gain in per capita income. By and large, incomes have been growing least in dollar amount at the less urban end of the spectrum; most at the moderately urban center of the spectrum; and by lesser amounts (but more than at the less urban end) at the metropolitan end of the scale. There are exceptions—Kentucky (a unique case because of the absence of any major urban center but with a metropolitan county), New York, North Carolina, Pennsylvania, and South Carolina—so many in fact that confidence in any generalization must be limited. But there does seem to be a mild tendency for moderately urban counties to provide larger per capita income increases. To the extent this is true, and to the extent that migration is absolute income-gain oriented rather than absolute income-level oriented, these moderately urban areas have a persistent, promising prospect.

Not the same can be said for the minor urban and rural counties. Their relatively low absolute income levels and low absolute amounts of income gain, combined with their historical outmigration pattern, do not permit viewing them in a similarly auspicious light. Despite garnering one-fourth of the Region's population gain in the 1960 to 1966 period, when income level and income gain considerations are added, their prospects are much dimmer.

Though the data are limited and somewhat ambiguous, Appalachia may be evolving a residence pattern that is urban but not metropolitan. Absolute income differences between metropolitan and moderately urban counties are declining, particularly where local urban population is over 25,000. Should the population and income data continue to be favorable, the Region could be a demonstration that an acceptable alternative to metropolitanization exists in at least part of the country.

The Appalachian experience also has some relevance for the questions about the efficient delivery of services. Experience shows that a policy of urban location of public facilities permits service to a rural population.

The Region's growth areas, the focus of investments, contain 12 percent of its area but 80 percent of its people.

There are actually two aspects to these questions concerning efficient service delivery: (1) reaching a sufficient scale of operation to be economical, and (2) providing adequate access by rural residents to the services. Both must be satisfied simultaneously. Adequate access to an urban center by a large rural population is the key that frequently is required for efficient operation of a diversity of services in that center. It is for this reason that the Commission has placed such emphasis on rural-urban linkages. It is commonly held that these are needed to provide services to the rural population and an adequate labor supply to the urban center. This is true, but equally true, they are frequently also needed to achieve economies of scale in the operation of facilities that are unattainable on the basis of the urban population alone. In the provision of efficient public services, particularly in health and education, the urban and rural parts of a growth area are dependent upon each other.

Mention has already been made of the fact that the Appalachian development program has two goals: the first emphasizes areas' economic competitiveness; the second, the ability of people to contribute and participate. The essence of a successful strategy is to serve these dual goals and, when they compete, to establish a priority between them. In the Appalachia program, the basic strategy is to enhance the competitive attractiveness of areas by augmenting their infrastructure, including those investments needed to deliver services directly to the population. Thus, area and personal opportunities are both served. However, if needed services to the population cannot be delivered from areas with significant economic growth potentials, service to the people takes precedence over areal upgrading.

The result is a hierarchy of areas in which investments are made. At one level, only those investments that are the sources of population-serving public activities are made, since the people concerned need improved prospects for economically successful out-commutation and outmigration. At other levels, area economic potential exists and appropriately scaled infrastructure investments for these purposes are also made.

Some have argued forcefully that the Regional Commission has established too many growth areas, and it has been argued that mobility and migration are the real solution to the Region's poverty. Added to these have been contentions that investment in people, not in economic development infrastructure, is the appropriate policy pattern. There may well be some truth to all of these contentions. However, policy realistically has to be a blend of assisting people to be capable of productive contributions and of assisting local areas and states to fulfill their potential economic role. If both of these can be served by growth areas that are moderately urban, accessible to a large majority of the population, and that can ultimately provide a wide range of public services efficiently, then the prospects for Appalachia and national urban policy are encouraging.

Marketing, Price, and the Theory of Communication

WAYNE D. PURCELL

PRICE is charged with the task of coordinating economic activity along the vertical continuum between producer and consumer. Activities at the various levels are related in a technical sense. How the technical interrelationships are handled operationally depends upon decisions by entrepreneurs at the various levels. These decisions are a function of the output of the prevailing communication system. Mounting evidence suggests the price system is incapable of functioning as an effective system of communication [4]. I contend that (1) the marketing economist must broaden his perspective to include analysis of the barriers to effective communication, whatever the origin of those barriers; and (2) the developing theory of communication can provide the tools needed to make such a reorientation of our research efforts productive.

On Communication Theory

Space limitations preclude a treatise on the theory of communication. Several references are cited [1, 2, 7]. I have developed elsewhere more complete treatments of the theory and how it can be employed in analyzing problems of inefficiency in marketing [4, 5, 6]. Only a brief discussion is possible here.

The basic process in communication involves the construction of a message by a *source* and the transmission of that message along some *channel* to a *receiver.* Feedback loops typically extend from the receiver back to the source, providing the basic mechanism for adjustment. The process of communication can become very complex. Actions of each party to the process are affected by the operating environment, by perception of role, by the level of training, and many other factors. Communication processes are continuous, dynamic, and always subject to pressures for change. Roles are reversible as the receiver acts as a source and vice versa—especially when time is a variable.

The communication theorist is interested in the necessary and sufficient conditions for effective communication. Since the theory of communication was born in the Shannon-Weaver work in 1949, development has

---

WAYNE D. PURCELL *is associate professor of agricultural economics at Oklahoma State University.*

been rapid and continuous [7]. Much of the research has been directed toward empirical verification of the relevance and relative importance of requisites to effective communication, which emerged from theoretical constructs.

Marketing as a System of Communication

Marketing is a communication process. The notion of pricing efficiency has long been used as a proxy for communication in discussing the extent to which our marketing systems succeed in their assigned task of coordination. What I am proposing is an approach to analysis that *emphasizes* the processes of communication inherent in any marketing system. A particular marketing system can be evaluated in terms of its relative effectiveness or ineffectiveness, as a communication system. Obstacles to effective communication are isolated and analyzed by employing the theory of communication and the requisites of effective communication processes as a standard. Possible corrective measures can then be drawn from the theory or formulated as hypotheses for further investigation.

The beef marketing system

In a study of the beef marketing system, a number of obstacles to effective communication were isolated.[1] Three of the more important will be discussed briefly.

One of the most important obstacles evolves from the continued use of clearly inadequate descriptive terminology. A fundamental requisite of effective communication is a descriptive terminology that requires a minimum of interpretation by the receiver. *Meanings are in the message users, not the message per se.* Differences in attachment of meaning is minimized by using a terminology that exhausts all significant categories within the normal range of variability. But researchers have found value differentials that exceed $100 between choice grade carcasses of comparable weights. How effective can the proverbial price signal be as a medium of communication under such conditions?[2] What we have called "pricing efficiency" is not being realized because price-related requisites of effective communication are not being met.

A second obstacle emerges from what I have labeled variable conditions of exchange. If communication efforts are to be effective, each party to the process must be cognizant of pertinent characteristics of the setting within which the interchange takes place. This requirement has been consistently violated in the beef marketing system.

---

[1] The study was conducted during 1965–1967 under a cooperative arrangement between Michigan State University and ERS, USDA.

[2] In a recent paper, Stout [8] reports "live price error" in cattle (actual live price compared with a derived live price based on retail values of the carcass) to range from —$3.36 to $3.78 per hundredweight.

To illustrate, consider the procedure that was typical in carcass grade and weight sales of slaughter beef prior to the regulatory action by Packer and Stockyards Administraton in the spring of 1968. Price was negotiated by weight and grade groupings, with the packer taking a "pencil shrink" to compensate for weight loss during chilling of the carcass. Under such an arrangement, "real price" can differ from negotiated price if pencil shrink differs from actual shrink.[3] A survey by USDA estimates that shrink for an overnight chill ranges from .5 to 1.5 percent [3]. But a 1967 Oklahoma survey revealed that 3.0 percent had developed as a standard pencil shrink. Oklahoma cattle feeders were taking pencil shrinks considerably above 1.25 percent (adopted as an arbitrary norm in the study) with resulting price distortions (absolute differences between negotiated price and real price) ranging in excess of $1.00 per hundredweight [9].

A third obstacle, a bit more abstract but very important, is the narrow perspectives adopted by system participants. Individualistic operating policies, perhaps inconsistent with policies that would facilitate superior system performance, are not unexpected. Such inconsistencies do prevail but are not the result of conscious weighing of individual desires against requirements for a viable and efficient marketing system. Many entrepreneurs simply do not perceive of their operation as part of a system.

Effective communication requires that all parties to the communication process understand how they relate to other participants in the system. We can only speculate as to how performance of the beef marketing system would change if each participant better understood his role as part of the total system. Recognizing the possibility of conflicts of interests, do we know whether it would be mutually beneficial if the degree of coordination between certain separately controlled activities were increased? A complete systems approach, encouraged by emphasis on the communication system, is needed to help remove the roadblocks to progressive adjustment which accompany narrow perspectives and completely individualistic operating policies.

A Final Observation

More work is needed to establish the potential of a research orientation that emphasizes the communication processes inherent in marketing activities. Such an orientation does decrease the relative importance given to price and the price mechanism. Price is an important part of a more complex communication system, but only a part. In our beef marketing system, price falls short as a medium of communication because other requisites of effective communication are not met. Perhaps it is time for our research priorities to be adjusted, permitting more attention to be paid the obstacles to effective communication and how these obstacles affect performance of marketing systems.

---

[3] Real price refers to the price derived by dividing carcass value, based on negotiated price and pencil shrink, by the actual weight of the chilled carcass. For example, real price on a 600-pound carcass (hot weight) with a negotiated price of $45.00, a pencil shrink of 3.0 percent, and an actual shrink of 1.5 percent would be $44 31 per hundredweight.

Concentration in Farming and Transition Bias

RONALD L. MIGHELL

NO fact about farming is better known than the continuing trend toward fewer and larger commercial farms. Less is known about changes in relative concentration of farming in different size groups. Are large farms growing faster than small farms? For evidence, observers usually turn to the convenient census economic classes (Tables 1 and 2). A first impression from such information is that increasing concentration is indeed taking place in the upper size classes.

But frequency distributions of this kind are not designed to measure changes in relative concentration in a growth situation. They are subject to a serious limitation, which may be termed transition bias. The purpose of this paper is to call attention to this limitation and to suggest what can be done about it.

Transition Bias

Transition bias arises from the passage, or transition, of numbers from lower to higher classes as growth takes place. The result is that comparisons between numbers in the same size class in two periods do not indicate relative changes for those that occupied the size class in the first period.

Suppose we consider an oversimplified example. A stand of trees is set out at the rate of 100 trees a year until 1,200 trees are planted. At the end of 12 years and 15 years, the age distributions are as follows:

Age class	Year 12	Year 15
Years	*Number*	
0–6	600	300
7 and over	600	900
Total	1,200	1,200

The numbers have decreased in the lower age group and increased in the upper one. Does this mean that aging has been more rapid in the upper age group? No, because the whole distribution is aging at the same rate. The distribution of the age classes about the rising average age is exactly the same in each year. The increase in the upper age class is due

[a] Adjusted to 1959 Census definition of commercial farms.

solely to the transition from the lower to the upper age class with the passage of time.

No one is likely to be trapped by this situation. But it is not so immediately obvious that the same kind of relationship may bias comparisons that involve economic classes in two periods of time. One reason is that we often lack other background information. Another is that there are a number of legitimate uses for such comparisons. For example, business firms supplying farmers or buying from them are interested in broad changes in numbers of farmers with certain dollar volumes of sales or purchases.

Transition Matrix Analysis

Preliminary graphic analysis of the data in Table 1 suggested that the relative reduction in farm numbers was about the same in all sales classes between 1959 and 1964. Similarly, the relative increase in sales per farm in all 1959 sales classes seemed nearly the same. This was tested by setting up the transition matrix shown in Table 3. Here it was assumed that the number of farms in each class decreased 17 percent from 1959 to 1964 (the average decrease in numbers of commercial farms). These decreases appear in the 0, or absorbing column. Then, beginning with the lowest class, enough farms were permitted to rise to the next higher class to balance out to the numbers shown in the 1964 distribution.

The farms that moved up to the next higher class represented the following percentages of the numbers in the 1959 class from which they came:

Moved up to next higher class from	Percent
$40,000–,99,999	18.3
20,000– 39,999	27.6
10,000– 19,999	29.8
5,000– 9,999	32.3
2,500– 4,999	28.0
Less than 2,500	30.1

These percentages are close to one another except for the 18.3 in the highest class. Such results lend support to the belief that, in terms of broad group tendencies, the effects of technology are widely spread through all the size classes of commercial farms.

Lorenz Curves

So far the discussion has centered on farm numbers. A method of taking account of both relative changes in number of farms and in value of sales is to use Lorenz curves. A Lorenz curve shows the cumulative percentage of farms on the horizontal scale and the cumulative percentage of sales of farm products on the vertical scale. Such curves can be approximated from the census data by economic classes. Then, by interpolation, readings can be made for corresponding percentage sectors for each year.

Such curves were prepared for 1959 and 1964 and the data in Table 4 read from them. These data indicate that percentage distributions in the two years were much alike, but with a tendency for a slight increase in sales in the highest two percentiles. Note that the increase shown in much less than that suggested in Table 2.

Table 3. Transition matrix showing shifts in number of commercial farms from 1959 to 1964

Sales class in 1959	Number in 1959	Number of farms in 1964								
		Value of sales class								
		0	$100,000 or more	$40,000 to $99,999	$20,000 to $39,999	$10,000 to $19,999	$5,000 to $9,999	$2,500 to $4,999	Less than $2,500	All farms 1964
dollars	*thousands*									
100,000 or more	20	4	16							
40,000–99,999	82	14	15	53						
20,000–39,999	210	36		58	116					
10,000–19,999	483	83			144	256				
5,000– 9,999	654	112				211	331			
2,500– 4,999	618	106					173	339		
Less than 2,500	349	60						105	184	
All farms 1959	2,416	415	31	111	260	467	504	444	184	2,001

Table 4. Percentage of total value of sales from commercial farms by specified sectors of the size distribution, United States, 1959 and 1964

Percentage sector of farm numbers	Percentage of total value of sales	
	1959	1964
Highest 10 percent	45.0	49.0
Second 10 percent	15.0	15.6
Second 20 percent	18.8	17.2
Third 20 percent	1[illegible].9	10.0
Fourth 20 percent	6.3	5.2
Lowest 20 percent	3.0	3.0
All commercial farms	100.0	100.0

Conclusions

The usual comparisons of economic class distributions of numbers of farms between two periods are affected by a transition bias, which seems to imply a faster rate of growth on the part of larger farms than is actually the case. When allowance is made for this bias, it appears that despite a considerable downward shift in numbers and an upward trend in size of farms the relative size distribution has not changed greatly. Lorenz curve analysis shows only a small tendency for an increase in sales in the highest percentiles.

Moreover, it is possible that the extra sales in the highest percentiles are offset by higher expenditures. Partial evidence about the kinds of farming involved and the kinds of expenditures and investment costs suggest this possibility.

A final word of caution should be noted. All of the discussion in this paper is in terms of national totals for commercial farms. Within these totals are many divergent and offsetting influences. Data for particular regions or types of farming may indicate quite different changes.

Computer Simulation of the Substitution Between Project Size and Management

S. F. MILLER AND A. N. HALTER

DURING the last several years, emphasis has been placed on comprehensive river basin planning and management. Many government agencies, both federal and state, have been established to perform this service. Traditionally, federal agencies have been single purpose or function oriented. However, with the issuance of Senate Document 97, comprehensive river basin planning has been stressed. This has enabled agency cooperation to develop general comprehensive plans for entire river basins, considering all beneficial uses of water.

Comprehensive planning of river basins is not easy. Basins that cover large geographical areas are complex systems containing many feedbacks and interactions that must be understood and quantified by the planning agency. Also, the water of a river basin can be used for a variety of purposes that are generally competitive in nature. Thus, in the situation where insufficient natural flow exists to satisfy all uses, the economic question occurs in selection among alternatives.

Alternative projects have traditionally been evaluated by means of benefit-cost analysis. Benefit-cost analysis, properly used, can be employed to determine the scale of development. But a misconception still prevailing in water resource circles is the belief that the size of the physical project is independent of project management. Even fellow economists have not applied the function of management in considering the proper size of a contemplated structure. For example, the expected flood control benefits of a project are calculated, "given the assumptions of constant flood probabilities, of reliable stage-damage relationships, and of correct operation of reservoirs" [1, p. 135].

In developing the project design, management of the project enters as a design variable in the form of the "rule curve." The curve specifies how full the reservoir is to be at any point in time during the hydrologic year. In developing the curve, consideration is given to the multiplicity of uses of the water and space of the storage facility and their relationship to the river basin system. Thus, during potential flood months the curve is low, while during the late spring and early summer it is high in an attempt to provide adequate water for irrigation, pollution abatement, recreation, etc. This, of course, does not mean that the reservoir will be at the speci-

---

S. F. MILLER *is agricultural economist with the Water Resources Branch of NRED-ERS, U.S. Department of Agriculture.* A. N. HALTER *is professor of agricultural economics at Oregon State University.*

fied level of the rule curve at all times, but rather that the rule curve guides to allocate space between opposed uses. Thus, management (rule curve or operating procedure) and the size of the project interact.

Modifying the management policy may be economically more advantageous than modifying the size of the project. It is conceivable, of course, to construct a project so big that all possible beneficial uses are fulfilled, thereby simplifying the management. But it is doubtful that such a system would be within any realistic cost constraints. The more general situation is that proper consideration of management allows the size of the project to be diminished without reducing net benefits. The relationship theoretically could be visualized in the traditional iso-product context shown in Figure 1.

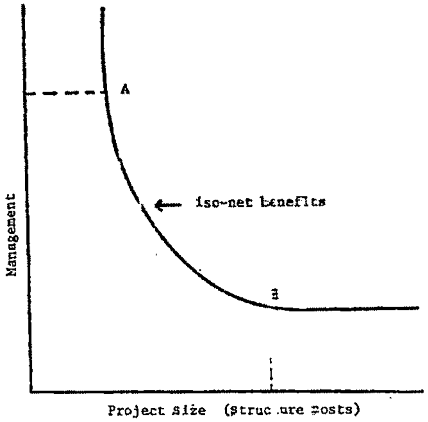

Figure 1. Substitutability between management and project size

We have shown an iso-net benefit curve which illustrates the possible substitution of management for project size. The diagram shows that an increase in management could reduce the size of project and still obtain the same net benefits. There exists a point, however, where management cannot continue to substitute for project size (point A) and a point where added size cannot substitute for management (point B). Although it is our hypothesis that equal net benefits can arise from different combinations of management and project size, the diagram implies that one can distinguish more management from less. This conceptual difficulty of the diagram should not detract from the idea of substitution; however, it does make it difficult if not impossible to empirically trace out either one iso-benefit curve or a family of curves for a response surface.

Objective

The objective of this study is to test the hypothesis that management can substitute for increased project size. To do so, a small river basin system was simulated on a digital computer and the effects of alternative structural sizes and management procedures evaluated in the form of accumulated net benefits.

Calapooia River Basin Simulation

The river basin selected to test our hypothesis was that of the Calapooia River located in the middle Willamette River Basin of western Oregon. In 1948 the Corps of Engineers proposed that a dam with an overall capacity of 97,000 acre-feet be constructed on the Calapooia at Holley, Oregon, and that the channel of the river be deepened below the dam. The project, however, was never funded. The Corps of Engineers has since initiated a re-study of the basin, consistent with Senate Document 97.

The simulation model that was developed for the Calapooia River Basin is discussed in detail elsewhere [2]. The major design variables were size of reservoir, size of channel, and operating rules. While the model is perfectly general in its consideration of structure sizes within its design range (0–97,000 acre-feet for the reservoir, and 5,000–21,000 cubic feet per second for the channel), we confined ourselves to investigating five alternative projects, shown in the first column of Table 1. These size structures were selected because the Corps of Engineers, at the time of this study, had estimated the use benefits and the structure cost that can be expected from these projects.

In order to evaluate the alternative projects, point-wise functions relating costs to reservoir and channel sizes were provided by the Corps of Engineers and incorporated into the model. The estimated benefit functions in dollars from the uses of water considered in this study were also provided by the Corps of Engineers. These included benefit functions for irrigation, flood control, drainage, and fish life.

As programmed into a model, the beneficial use potentials are functions

Table 1. Summary of simulation results

Project number	Capacity		Accumulated total annual costs	Accumulated net benefits		
	Reservoir	Channel		Unmodified	3 percent increase	6 percent increase
	acre feet	*cubic feet per second*	*thousand dollars*			
R97C21	97,000	21,000	114,584	33,277	49,689	49,697
R97C11	97,000	11,000	97,115	24,308	35,720	35,727
R97C5	97,000	5,000	87,083	8,623	16,157	16,165
R67C21	67,000	21,000	97,046	20,241	22,885	23,605
R67C5	67,000	5,000	69,545	−10,406	−7,833	−7,109

of the reservoir size, the channel size, or the operating procedure. Irrigation benefits are a positive function of storage capacity of the reservoir. As storage capacity increases, the irrigable acreage also increases. Flood control and fish benefits are dependent not only on reservoir size but also on channel size. Drainage, on the other hand, is related only to the size of the channel.

Results of Computer Runs

The computer model simulates the hydrology by a modified stochastic approach over a one hundred year period. Thus the benefits arising from a project are random variables with a distribution and mean. One hydrologic trace provides a single estimate of accumulated annual net benefits. Other estimates could be obtained by using different hydrologic traces; however, this was not done in this study A hundred year period was used for both the economic and physical life of the project because it was the period assumed by the Corps of Engineers For each modification in the model, the same hydrology is generated in order that the effects can be compared.

Using the suggested rule curve supplied by the Corps of Engineers, the accumulated net benefits in the "Unmodified" column of Table 1 were generated. It was noticed, however, that inadequate water during critical periods of the year limited the fish benefits. These periods generally occurred during the late summer and early fall as a result of the low natural flow in the channel. The low reservoir level, caused by the need for flood storage in the late spring and by releases for irrigation, precluded supplemental release for fish maintenance. It was therefore decided to test the consequence of a change in management by increasing the rule curve three percent over most of its range. A priori, one would expect a reduction in flood control benefits because less storage is available to capture flood waters but an increase in irrigation and fish benefits. As expected, fish benefits did increase for all projects. Irrigation benefits in the small reservoir projects also increased slightly. However, flood control benefits for all projects remained virtually unchanged. The resulting net increase in accumulated net benefits to all projects is given in Table 1.

Because of the increased accumulated net benefits, a further increase of the curve was tested. The rule curve was increased by an additional three percent, for a total of six percent. As seen in Table 1, virtually no change occurred in the accumulated net benefits, suggesting that further modification would not be beneficial.

Out of these three management policies, however, we are able to identify three points on the management-structure size isoquant if we assumed that the change in management policy constituted an increase in management. Project R97C21 with the unmodified rule curve yielded net benefits totaling $38,277,000. Project R97C11 with the rule curve increased by both three and six percent yielded approximately the same accumulated net benefits, $35,720,000 and $35,727,000, respectively. If size is measured in terms of the accumulated total annual costs, Project R97C21 costs $114,504,000 and Project R97C11 costs $97,115,000. Thus, the first and the second management level are somewhere in the substitution zone marked A-B on Figure 1. The second management level required less total cost but increased management. The third management level is above point A. Accumulated total annual costs are the same and management has increased. Conceptually, what has happened is that an increase in the rule curve (increase in management) has substituted for capital input. Of course, from an empirical standpoint, quantitative measures of rates of substitution are difficult if not impossible to measure because of the difficulty of placing management on a cardinal scale.

Conclusions

On the basis of these research results, the following conclusions appear warranted: (1) It is believed that management and project size are substitutes. Specifications of sources of substitutability provide a fertile field of inquiry for water resource researchers. (2) Proper management needs to be given greater consideration in project planning. (3) Computer simulation appears to be a promising approach to river-basin planning and development. It is capable of considering changes in project scale as well as changes in management procedures.

An Economic Model for Determining Cotton Allotments and Prices to Maximize Net Farm Income*

Fred Sobering, Leroy Quance and Luther Tweeten

ECONOMISTS have long used linear programming as a tool in farm management and policy research. Research reported herein complements linear programming of representative farms with regression and marginal analysis to determine: (1) the impact of various cotton price-allotment combinations on net farm income (profit) and enterprise levels on well-organized farms in Southwestern Oklahoma[1]; (2) the national cotton price support and allotment levels maximizing farmers' net income, given the level of federal expenditures on the cotton program; and (3) the value of an acre of cotton allotment.

Cotton Production Response to Changes in Allotments

Changes in cotton production at specified levels of allotments and cotton prices are summarized in Table 1. The relationship between cotton allotments and cotton production is formalized in the elasticity E_{OA} of cotton output with respect to acreage allotment. It shows the percentage change in output corresponding to a one percent change in acreage allotments. Theoretically, we would expect a small elasticity at low cotton prices because cotton is unprofitable—it does not pay to expand output even though the allotment is increased. We would also expect an elasticity of less than one at high allotments because all land suitable for cotton is utilized, and further allotment increases are used either on poorer land or not at all.

Estimates in Table 1 confirm slippage in cotton allotments; for example, with a cotton price of $26.40 per hundredweight and with allotments from 100 to 115 percent of the 1963 base, each one percent decrease in allotment would reduce production only .92 percent in Southwest Oklahoma.

To check the realism of the computed elasticities, actual data on allotments and cotton output for Oklahoma and Texas for the years 1961 through 1964 were used to compute the output-allotment responses. From 1961 to 1964, allotments were reduced from 8 733,000 to 7,629,000 acres, or

[a] The elasticity of cotton output with respect to acreage allotment, showing the percentage decrease in cotton production associated with a one percent decrease in cotton allotment.

[b] Return to land, operator labor, and management.

12.64 percent. Output was reduced from 5,135,000 bales to 4,540,000 bales. For this time period, the actual E_{OA} was 0.91. This compared closely to the predicted values in Table 1. Similarly, the actual E_{OA} for the period 1962–1964, in which allotments were reduced 10.88 percent, was 0.88—very similar to the computed values for the aggregate area. However, the actual E_{OA} varied considerably from year to year. For example, for 1962 to 1963 it was .52; from 1963 to 1964, when allotments were decreased by a fraction of a percent, it was 7.049. Actual elasticities from consecutive years are greatly influenced by yield variations due to weather and factors other than the allotment level. Such variations make it extremely difficult to determine precisely the adjustment in allotment required to realize a desired goal of output reduction on a year-to-year basis. Over a longer period of time, the elasticity predicts outcomes with greater reliability, as indicated above, and a knowledge of E_{OA} is helpful in formulating commodity price support-allotment programs.

Farm Income

Net farm income or profit in Table 1 is gross farm receipts less expense. other than for land and for operator and family labor and managements

With allotments set at 100 percent of the 1963 level, average net income ranges from \$5,669 per farm with the cotton priced at \$17.60 to \$8,859 per farm with cotton priced at \$30.80. And with a given cotton price, net farm income decreases with lower cotton allotments. Thus, cotton prices and allotments have major impacts on net farm income.

Optimal Cotton Allotment-Price Combination

A national cotton allotment-price combination that maximizes net farm income to operator labor and management for the area under consideration was computed. It is not expected that such a combination would maximize returns for each and every soil situation and/or assumed representative farm situation within Southwest Oklahoma, or in the rest of the nation—to which the support prices and allotments would also apply. The formulation avoids the macro-micro inconsistency by assuming that all regions would receive adjustments from the 1963 level of support prices and allotments similar to adjustments received in Southwestern Oklahoma.

The aggregate net income function for Southwest Oklahoma was estimated by least squares regression from the aggregate net income data of Table 1:

$$\begin{aligned} Y &= 10{,}287.286 - 189.1818X_1 - 430.31957X_2 + 9.43723X_2{}^2 \\ &\quad + 10.34763X_1X_2 R^2 = .997 \end{aligned}$$

Where

Y = area aggregate returns to operator labor and management (\$1,000)
X_1 = allotment level as percent of 1963 base
X_2 = cotton price in dollars per hundredweight

Coefficients on X_1 and X_1X_2 were significant at the 99 percent level.

The government outlay equation based on domestic and foreign cotton demand, but adjusted to Southwest Oklahoma prices and share of national production, is:

$$G = -2991.5 + 11.09X_1 + 84.997X_2$$

Where G = level of government outlay (million dollars).

The equation shows the cotton price-allotment combinations that are available to cotton producers when the government spends G on a cotton program. The equation becomes the demand constraint in the following profit equation. Assuming, for illustrative purposes, that government outlay was \$553 million, the profit equation is:

$$\begin{aligned} \pi &= 10{,}287.286 - 189.1818X_1 - 430.31957X_2 + 9.43723X_2{}^2 + 10.34763X_1X_2 \\ &\quad + \lambda(553 + 2991.5 - 11.090002X_1 - 84.996622X_2) \end{aligned}$$

Where $\lambda \neq 0$ is an undetermined Lagrangian multiplier, π is profit (net farm income) and X_1, X_2 are as defined above.

The partial derivatives of π with respect to X_1 and X_2 are set equal to zero:

$$\frac{\alpha\pi}{\alpha X_1} = -189.1818 + 10.34763X_2 - 11.090002\lambda = 0$$

$$\frac{\alpha\pi}{\alpha X_2} = -430.31957 + 18.87446X_2 + 10.34763X_1 - 84.996622\lambda = 0$$

$$\frac{\alpha\pi}{\alpha\lambda} = 3544.5 - 11.090002X_1 - 84.996622X_2 = 0$$

Solving the above equations $\alpha\pi/\alpha X_1$ and $\alpha\pi/\alpha X_2$ for X_2 in terms of X_1, the results are: $X_2 = .171226X_1 + 16.87204$.

Substituting this value of X_2 into the equation for $\alpha\pi/\alpha\lambda$, the numerical value of X_1 is 82.3. The numerical value of X_2 is 30.96. Thus the profit maximizing combination of cotton price and allotment level for the Southwest area with a $553 million national government outlay is 82.3 percent of base allotment with a $30.96 per hundredweight cotton price.[2]

The results show that Oklahoma farmers who grow cotton receive a greater income with high national price supports and small national allotments than with low price supports and large allotments. Given a choice between small and large allotments that would apply proportionately to all cotton allotments in the nation, the cotton producer will receive a higher income with small allotments. This result depends on the elasticity of demand for U.S. cotton. The demand function used above is valid for approximately a five-year run. In a longer period, demand becomes more elastic as higher prices retard consumption through encouragement of synthetic substitutes and encouragement of foreign cotton production. In a period longer than five years, farm income might be greater with lower prices and larger allotments, given the government outlay for cotton programs.[3]

Value of Cotton Allotment

Data from the study were used to calculate the maximum average value of an acre of cotton allotment for various farm situations with allotments reduced 15 percent below the 1963 acreage. The 15 percent reduction in the clay soil farming situation at a cotton price of $26.40 per hundredweight necessitated a reduction in cotton of 17.86 acres. Returns to land, labor, and management were reduced by $183 in total, or an average of $10.25 per acre. The full value of this acre of allotment is the present value of its future income discounted to the present. Capitalizing the $10.25 net return per acre in perpetuity at 5 percent, the present capital value of an acre of allotment on clay soils was $205. This capitalized value was the maximum amount that the operator could afford to pay for an additional acre of allotment. Returns to operator labor and management would have to come out of the $10.25 annual amount. If he paid $205 to purchase an acre of cotton allotment, the operator would realize no return on the allotment to his labor and management.[4] Comparable average maximum values of cotton allotments for sandy, level loam large, level loam small, rolling loam large, and rolling loam small farms were $560, $159, $425, $238, and $325 per acre, respectively.

---

[2] The national price is $35.18 but adjusted to Oklahoma is $30.96. The national allotment is equal to 82.3 percent of the 1963 allotment. Second order conditions for a maximum were met.

[3] The analysis was carried out under the assumption that a reduction in cotton allotment did not necessitate idling an equivalent number of cropland acres. Programming results indicated that forced idling had little effect on net returns when contrasted with a reduction in allotment without forced idling. The value of enterprises forced out by mandatory idling of land was low. Idled land was largely reseeded cropland and fallow land.

---

[4] If operator labor valued at $3 per acre were subtracted from the annual value of allotments, the revised annual value of allotment would be $3 less per acre and the capitalized value $60 less per acre for each representative farm. A shorter planning horizon also would reduce the capitalized value.

VIGNETTES: PRICE ANALYSIS AND MARKETING

CHAIRMAN: SHARON Q. HOOBLER, FEDERAL EXTENSION SERVICE

Effect of Merchandising Methods on Prices Paid at Cooperative Feeder Cattle Sales*

DAVID L. COLE

SPECIALIZED feeder cattle auction sales are held in all major beef production states. These sales have been developed primarily to market more effectively the feeder cattle produced by relatively small producers. Historically, the small feeder cattle producers have found themselves in a difficult market position because individually they lack sufficient volumes of uniform cattle to attract buyers to their farms. Their only market alternatives were local slaughter auctions or country buyers. As a result, small farm operators combined their cattle to obtain sufficient volumes to attract buyers. This was done under the assumption that cattle of varying grades, weights, and breeds were differentiated products in the minds of the buyers when available in sufficient quantities.

The purpose of this study was to analyze empirical data to identify and, when possible, to quantify the effect that specific economic factors have on the performance of feeder cattle auction sales. It has previously been shown that larger lot sizes and uniform cattle by grades, sex, and breed were significant factors in feeder cattle buyer decisions [1, p. 98]. It was also reported that the size of sale lot was important to the buyers of feeder cattle. It should therefore be recognized that, with variability in the feeder cattle that can be offered for sale, the quality of the lot is a major element in the buyer's decision to purchase feeder cattle and the price he is willing to pay. Hence, it is essential that producers and marketing agencies recognize the importance of this variability and understand how they can merchandise feeder cattle to sell to their advantage.

Methodology

The data used in this presentation were obtained from eight graded cooperative beef feeder cattle sales in 1966 and seven in 1967, conducted by the Michigan Cooperative Feeder Cattle Sales Association. Most of

DAVID L. COLE *is assistant professor of agricultural economics at Michigan State University.*

this information was obtained from the standard sales program available at the special auction sales.

The statistical method used to determine the influence of the independent variables on the price paid for feeder cattle was multiple regression and correlation analysis. Detailed market summary tables were used to aid in interpreting and generalizing results obtained. The market analyses were presented in an aggregative manner. However, individual market analyses also were made. Results of individual market analyses are studied in conjunction with the characteristics of each market's facilities and clientele before making recommendations. Two models were used to test the influence of factors on the prices paid for feeder cattle [2].

Model 1 was:

$P_{ijkl} = a + b_1G_i + b_2W_j + b_3L_l + b_4S_k + e_{ijkl}$ where
P_{ijkl} = average price paid per pound at the feeder cattle sales.
G_i = grade of the animal, $i = 1$ through 6, as shown in Table 1.
W_j = weight class, $j = 1 \ldots 13$, as shown in Table 1.
L_l = size of sale lot as a continuous variable.
S_k = sex of calf, $k = 1, 2$ for steer and heifer respectively.

Model 2 was like Model 1, except weight was treated as a continuous variable and lot size was divided into subclasses, as shown in Table 1. The variables considered were the variables found to be statistically significant by Cole in the Wisconsin Study [1, p. 98].

Results

Analysis by grade

In both models, grade was included as a dummy variable with the choice grade used as base. The U.S. Department of Agriculture official grade classifications were used, and grading was done by the Michigan Department of Agriculture. In some cases borderline cattle were combined into one lot, resulting in grade classifications of Choice to Prime and Good to Choice.

Regression analysis indicated that there were significant differences between the prices paid for Choice cattle and most other grades. In all cases differences were shown, but the differences were not significant for the Choice to Prime grade classifications in the 1966 sales and for the Good to Choice grade classifications in the 1967 sales (Table 1). The models indicated that for each full grade increase from Good to Choice and Choice to Prime, there was a general increase of $1.50 per hundredweight (Table 1). Cattle grading standard sold on the average for $6.77 less than Choice grade cattle.

[a] Standard error of the regression coefficient between 0.19 and 0.99 for the estimate discrete values, weight, grade, and lot size.

Analysis by size of sale lot

Lot size was analyzed both as a continuous variable in Model 1 and as in discrete subclasses in Model 2. Lot size as a continuous variable showed that the number of cattle in the lot is a factor having significance for the buyer. Results were significant at .01 significance level and indicated that, as lot size was increased by one head in the range of 1–75 head, the price paid for each animal in that lot increased by $0.03 per hundredweight in 1966 and 1967 sales.

In Model 2, lot size was studied as a discrete variable, with size breakdown ranging from as few as 1–5 head per sale lot to as many as 66–75 head per sale lot. The deleted classification, or base to which the prices received for other classes were compared, was 16 to 25 head per sale lot.

Cattle selling in the 1–5 head lot classification received on the average $0.75 per hundredweight less than those in the 16–25 head lot size sale group. No additional significant differences from the base group were found between classifications until the lot size reached 46–55 head grouping in 1966 and the 56–65 head grouping for both 1966 and 1967. There were no lots larger than 65 head in the 1966 sales data nor any lots larger than 66–75 sales grouping in 1967.

Analysis by weight

Weight was studied as continuous and with discrete subclasses, as shown in Table 1. It was shown to be a significant factor when included in Model 2 as a continuous variable. As the average weight of a lot increased or decreased by 100 pounds in the range of 250 to 800 pounds, price was changed in inverse fashion on the average of $1.50 to $1.74 per hundredweight.

Analysis by sex

Sex (steer or heifer) was included in the analysis as a discrete variable. Heifers received significantly lower prices per hundredweight than steers in both the 1966 and 1967 sales. The $4.40 and $4.28 reductions in heifer prices per hundredweight as compared with steer prices primarily reflect the market for the fed cattle product.

Summary

A study of the factors affecting prices paid for feeder cattle at Michigan Cooperative Feeder Cattle Sales during 1966 and 1967 was conducted. Regression analysis with price the dependent variable indicated there were significant differences between the prices paid for Choice grade cattle and most other grades. Each full grade change from Good to Choice and from Choice to Prime showed a general increase of $1.50 per hun-

dredweight. Standard grading cattle were on the average discounted $6.77 per hundredweight less than Choice grading cattle.

The number of cattle on the sale lot were shown to be a significant factor affecting the price paid by buyers at the Michigan Cooperative Feeder Cattle Sales. Lot size viewed as a continuous variable indicated that the sale lot size was increased by one head in the range of 1–65 head, but on the average the price paid for the lot increased by $0.03 and $0.034 per hundredweight for each animal in the lot in 1966 and 1967, respectively.

When lot size was viewed with subclasses, it was found that, except for cattle in the 1–5 classification, no significant value differences were found between lot classifications and the base grouping until the number of head sold reached 46–55 head, as indicated by the 1966 data, and 56–65 head, as indicated by both the 1966 and 1967 data. Cattle sold in lots of 56–65 head received $2.00 and $2.77 per hundredweight (significant at the point at the .05 level) more than did those cattle sold in lots of 16–25 head for 1966 and 1967, respectively.

As the average weight of a lot decreased or increased by 100 pounds in the range of 250 to 800 pounds, price was changed in an inverse fashion on the average of $1.50 to $1.74 per hundredweight. When weight was divided into 50-pound classifications, it was shown that weight was a critical factor in the buying decision.

Steer calves received on the average $4.40 and $4.28 per hundredweight more than heifers in 1966 and 1967 respectively. This difference can be largely attributed to the market for the fed cattle product.

Allocation of Florida Orange Production Among Alternative Product Forms and Market Sectors*

DAVID E. WEISENBORN

The Problem

AN important decision made each year by the firms comprising the Florida orange industry involves the allocation of a given supply among alternative product forms and marketing sectors. One criterion for this allocation is maximization of net revenue, which requires a knowledge of the relevant demand and cost relationships existing for the various product forms in the various marketing sectors. This paper reports the results of estimates of marginal revenues and marginal costs and their use in an allocation scheme that would maximize net revenue to the Florida orange industry.

The allocation process involves both the alternative forms of the final product (fresh oranges, frozen concentrated orange juice, chilled orange juice, and canned single strength orange juice), and the three alternative market sectors (foodstore, institutional, and export). There are several other product uses of Florida oranges, but the four product forms noted account for approximately 90 percent of the utilization of an annual crop.

While the methodological framework for solving optimal allocation problems for agricultural industries has been available for several years [2], there has been no previous attempt to apply the available methodology to an allocation of a given supply of Florida oranges over both alternative product forms and marketing sectors. The problem was previously defined to maximize total returns among various products in the foodstore sector by Minden [1].

The Data

With four product forms marketed through three market sectors, an attempt was made to estimate twelve different demand equations [3]. The data were obtained from numerous primary and secondary sources, and each of the equations was estimated at f.o.b. processor level using a single equation least squares linear regression model. Of the original twelve equations for which estimates were attempted, four were unacceptable.

DAVID E. WEISENBORN *is assistant professor of agricultural economics at the University of Georgia.*

The remaining eight functions, however, represented the major products in each marketing sector and accounted for approximately 80 percent of utilization of an annual crop (Table 1).

Constant marginal cost functions were developed for each of the four product forms noted above [3]. Since the allocation problem was limited to the f.o.b. processor level, the cost estimation work relates basically to the fresh fruit packing and/or processing activities.

Table 1. Actual net revenue for the average season using actual quantities sold in each product-market category and maximum net revenue for the average season with a total quantity constraint of 73.22 million boxes, f.o.b. processor level.[a]

Product and market sector[b]	Actual		Maximum	
	Quantity	Net revenue	Quantity	Net revenue[c]

Total	73.20	16.07	73.22	27.48

[a] The quantity means are based on data from October, 1961, to October, 1967, for the foodstore and export product forms and December, 1963, to December, 1966, for institutional product forms.

[b] FCOJ is frozen concentrated orange juice, COJ is chilled orange juice, CSSOJ is canned single strength orange juice, FFO is fresh Florida oranges; F is foodstore, I is institutional, and E is export market sector.

[c] Negative net revenues arise in the optimum allocation when marginal net revenues are equated before fixed costs are covered.

The Model

Optimum allocation of a given season's production to various product categories and/or market sectors is based upon the theory of price discrimination. The problem was to determine the maximum net revenue for the Florida orange industry by equating the marginal revenue and marginal cost functions for the entire industry. The marginal revenue equations were derived from the demand equations for each product-market, while the constant marginal cost functions were developed from linear total cost functions. The constant marginal costs were deducted from the estimated marginal revenue functions to yield marginal net revenue functions. Maximum net revenue was then derived by an allocation that equated the marginal net revenue functions among product forms and markets.

Quadratic programming and the calculus with LaGrangean multipliers were two alternative methods considered for solving the revenue maximization problem. The calculus method was chosen because of its relative simplicity and programming ease.

The Results

The allocative procedure was carried out by solving the system of net marginal revenue functions for the quantity values. If the allocation is performed with no quantity constraint, the net marginal revenue functions are equated at zero. If total quantity is fixed, the net marginal revenue functions are still equated, but not necessarily at zero.

Actual quantities sold in each product-market were calculated for the average period used in the demand analysis. The actual net revenue figures were also calculated for each product-market at the f.o.b. processor level (Table 1). For the eight product-markets in the average season, the net revenue was estimated to be a positive 16.1 million dollars for 73.2 million boxes of oranges.

When the total quantity of oranges to be allocated was constrained to the average season quantity of 73.2 million boxes, maximum net industry revenue is approximately $27.5 million at the f.o.b. processor level (Table 1). This represented an increase of $11.4 million over the actual net revenue obtained from a comparable set of product-markets and total supply. A supply of 73.2 million boxes for the eight selected product-markets represents an overall Florida supply of 91.5 million boxes.

With supply unconstrained, net f.o.b. processor revenue was maximized at 111.4 million boxes for the eight product-markets or a total supply of about 139 million boxes. More importantly, the net revenue for the unconstrained solution was $85.4 million or $69.3 million above the actual net revenue for an average season. This allocation provided the largest overall net revenue among those attempted and resulted in sales of 24 million boxes of fresh oranges. This appeared unreasonable, given the competitive relationships existing between Florida, California, and Arizona for fresh oranges.

A subsequent unconstrained allocation excluded fresh oranges, which were arbitrarily set at 15 million boxes (Table 2). Net industry revenue was then $77.9 million and the optimum supply was reduced to 102.3 million boxes, as opposed to 111 million boxes when supply was unconstrained. A supply of 102.3 million boxes is equivalent to an overall industry supply of 128 million boxes.

Table 2. Maximum net revenue with unconstrained processed product markets and an upper constraint of 15 million boxes of oranges in the fresh foodstore sector

Product and market sector[a]	Quantity	Net revenue	Product and market sector	Quantity	Net revenue[c]
	million boxes	million dollars		million boxes	million dollars
FCOJ —F	34.17	32.48	FCOS —I	8.14	– 3.77
COJ —F	9.79	37.54	COS —I	11.86	17.74
CSSOJ—F	15.20	7.84	FCOS —E	5.95	– 2.14

[b] Not included in the unconstrained allocation.
[c] See footnote c, Table 1.

Conclusions

The results of this study relate to the maximization of net industry revenue at the f.o.b. processor level. If, instead, the problem has been solved for maximization of net revenue at the grower level, the optimum industry supply would be somewhat less than the amount obtained for the f.o.b. processor level, since the price elasticities of demand are believed to be relatively more inelastic at the grower level.

The economics of price discrimination, as applied in this study, attempts to maximize the overall industry net revenue. In doing so, several product-markets suffer losses. If industry policy were formulated to require the maximization of net revenue, several product-markets would be expected to seek subsidies.

Finally, in the years that supply exceeds the estimated optimum, some form of abandonment or internal supply management would be necessary. Implementation of supply control programs normally requires state or federal legislation for enforcement.

Criteria for Defining Federal Milk Order Market Areas

ROBERT E. JACOBSON

IN the regulation of fluid milk markets, definition of the market area in precise geographic terms is a critical issue because the designated market area is the basic means for identifying what milk is to be pooled and priced. The U.S. Department of Agriculture historically has emphasized two criteria in its decisions on boundaries of Federal order marketing areas. These criteria include (1) all of an area where the same milk dealers compete with each other for sales of milk, together with (2) the area where such milk must meet essentially the same sanitary inspection standards. An additional implicit consideration has been the tacit support or lack of specific opposition by the relevant producer interests, since it is the producer who finally votes in approval or rejection of the total order regulation.

In recent years, shortcomings of the specified criteria have become apparent due to the several technical and economic innovations in fluid milk marketing that have changed the structure of the industry from one of smaller individual markets to one of larger regional complexes. In spite of limitations of the market area criteria, the Federal order program has necessarily had to reflect the changes in the industry and extend market areas. As stated by the director of the Dairy Division, "With respect to larger geographic milk markets, the continuing expansion of Federal orders into previously unregulated areas and the merger of formerly separate orders testifies that the orders have been adapting to the fact that markets for fluid milk are rapidly becoming regional rather than local in scope" [1, p. 111].

Since present criteria for defining marketing areas are considered to be limited for optimal market delineation, a review of present criteria and identification of additional criteria should be helpful to the public decision process.

Both legal and economic considerations are relevant dimensions of the market area question. In a legal sense, the Agricultural Marketing Agreement Act of 1937 implied substantial flexibility to Federal milk order market areas by offering no direct limitations to market area size. In reviewing this factor, the Nourse Committee stated that " . . the Act is interpreted by the Department to require that milk marketing orders be issued for marketing areas in which the conditions of demand and supply are reasonably homogeneous" [4, p. 11].

ROBERT E. JACOBSON *is professor of agricultural economics at The Ohio State University.*

In an economic sense, usual definitions referring to a market as a closely interrelated group of buyers and sellers offer a general framework for evaluating market area. The essential question then concerns what criteria best describe the interrelatedness of buyers and sellers in fluid milk marketing.

Criteria for Market Area Definition

In addition to the criteria of competing dealers, uniform sanitary standards, and producer support, which have been utilized in market area decisions, measures of procurement area, general market organization, and Class II processing-distribution are advanced in this paper as relevant criteria.

Continued use of the area where the same milk dealers compete for sales is not arguable as one fundamental measure of what the regulated area should reflect. Probably no better means of achieving the orderly marketing objectives of the regulatory program exists than the systematic use of this measure. Sales area evidence is essentially a direct observation of the inter-relationship of buyers and sellers. However, this criterion does not answer the question regarding how extensive relationships must be to be viewed as the same market. Also, primary emphasis on competing handlers' sales territories for defining marketing areas is apt to make the regulatory program overly responsive to the distribution decisions and adjustments being made by milk dealers.

Uniform sanitary standards must continue as a factor in market area determination, but this factor is one of less importance than formerly. Extensive uniformity in sanitary standards has been accepted, and most markets are, therefore, not limited in a practical way by varying Grade A requirements. Widespread adoption of the U.S Public Health Service recommendations by state and local health departments, implementation of the Interstate Milk Shippers Program, and general employment of reciprocity arrangements among markets have all served to erode sanitary standards as a significant criterion for market area definition.

Acceptance and support of the market area proposal by producers (cooperatives) is a pragmatic consideration which cannot be avoided in the regulatory procedures. While such acceptance is essentially remote as an indicator of buyer-seller relationships, required producer support in referenda diminish the possibilities of rejecting this factor, at least in the short run.

The procurement area is becoming an increasingly important criterion in defining marketing areas. This is due in part to the greater mobility of milk in procurement through bulk assembly. The procurement criterion becomes of particular importance when there is substantial milkshed overlap with potentially unstabilizing differences in producer pay prices.

In some market area decisions, the procurement area aspect has already been articulated as a rationale for defining the market area. For example, in connection with the merger of the Muskegon and Southern Michigan Federal orders, the decision stated: "The overlap of distribution and supply routes has progressed to the point that a separate Muskegon market for producers can no longer be distinguished . . . By providing proportionate sharing among all producers of total Class I sales in the market, the merger will stabilize prices and eliminate much of the present price uncertainty . . ." [3, p. 7904].

It seems logical to recognize directly the procurement area as a market area criterion (1) if it is already on occasion being considered on that basis, and (2) if it adds substantively to the description of buyer-seller relationships. Since matters of price instability and equity are recognized concerns of the Federal order program, and since procurement area relationships have a major effect on these matters, procurement area evidence should be used as a basic measure for market area definition.

General market organization as a marketing area measure implies a simultaneous look at some of the elements of both procurement and distribution. The problem of using this criterion is that it eludes the precise definition required for introducing and analyzing relevant evidence in the public decision process. However, the value of general market organization is that it can add essential elements to the description of buyer-seller relationships. Dimensions of general market organization that can be more precisely evaluated include (1) working relationships among cooperatives, (2) compatibility of Federal order provisions, and (3) market structure and organization (milk dealers) [2, p. 23].

Working relationships among cooperatives are particularly important because moves to larger or consolidated marketing areas usually mean that several cooperatives will be affected and will be operating within the same regional market order. The extent of working relationships among cooperatives can be observed in terms of (1) federations for bargaining purposes among the subject cooperatives, and (2) cooperation in meeting full supply requirements and disposition of surplus milk.

Increased uniformity and integration of provisions among Federal order markets de-emphasizes compatibility of order provisions as a factor in defining market areas. However, variations in seasonal price plans and Class I pricing procedures (particularly supply-demand adjustors) continue to indicate that such variations must be recognized as the market area definition is reviewed.

Evidence on market structure and organization offers a direct observation of interrelationships among buyers and sellers. Priority information in this area includes operations of national and regional dairy firms, national and regional food store chains, vertically integrated fluid milk operations, arrangements between handlers for reciprocal processing, and highway transportation in the proposed area.

Class II processing-distribution as a factor in market area determination has become significant in recent years due to (1) increased concentration of Class II product processing in a small number of large plants, and (2) wider application of the Grade A requirement on Class II products, particularly intermediate products such as ice cream and cottage cheese. As a result, some Federal order markets are necessarily pooling surplus milk to be used in intermediate products and destined for other markets, while such other markets are maintaining high utilizations and are depending on the outside sources for these products. This type of situation raises a basic question of equity and sharing of surplus among markets since it leads to wide variations in utilization among markets. Therefore, inclusion of evidence on Class II processing-distribution in defining market areas would provide further information on buyer-seller relationships and would help resolve one unstabilizing aspect of market area delineation.

Evaluating Criteria for the Public Decision

It is postulated that consideration of the several criteria offers a stronger and more balanced base for identifying the optimal market area than does the more limited emphasis on sales and sanitary standards. Furthermore, consideration of the six factors divorces the regulatory program from some of the uncertainty associated with dynamic adjustments taking place in distribution patterns. The question remains, however, as to how evidence on the several criteria can be integrated to provide a best decision on boundaries of the market area.

It is recognized that each measure may suggest something different with respect to size of maketing area. Also, any single measure taken by itself could have implications finally suggesting, for example, a national marketing area. To keep this type of total area decision in perspective, it is emphasized that by using the six criteria concurrently, with no preference given to any of them, and letting the evidence on each criterion determine its relative merit, a balanced type of judgment should be realized that will provide the most effective type of marketing area.

As a final note, an additional option should be utilized by the U.S. Department of Agriculture and recognized directly in market area decisions. Historically, market area expansions have been made by (1) adding unregulated adjacent areas to the marketing area, and/or (2) consolidating marketing areas. A third option, that of transferring a portion of one market area to another Federal order is becoming more relevant and should be part of market area policy. The rationale for needing this option is that, in given situations, milk market relationships have changed so much that earlier marketing area formulations do not reflect the state of current marketing relationships. A portion of one market may now be more closely associated with an entirely different market. The regulatory program should have the flexibility of recognizing such changes as market area decisions are made.

Price Discrimination in the Food Industry: A Competitive Stimulant or Tranquilizer?

R. E. SCHNEIDAU AND RONALD D. KNUTSON

THE food industry has played a central role in the establishment, evolution, and interpretation of the Robinson-Patman Act. In 1934 the Federal Trade Commission (FTC) chain store investigation found that discriminatory price concessions given chains by food processors were in part responsible for the chains' competitive advantage [2, p. 155]. This landmark investigation of the food industry contributed materially to the ultimate passage of the Robinson-Patman Act in 1936 [14, p. 171].

Through time, discriminatory practices of food processors and the exacting power position of chains have continued to play a central role in the interpretation and enforcement of the Robinson-Patman Act.[1] The National Commission on Food Marketing found that from 1951 to 1964 the FTC had made 1,792 formal investigations of discriminatory preferences affecting retail food distribution [14, p. 172]. Between June 1950 and June 1964, the FTC filed 53 complaints against food marketing concerns charging illegal discrimination [14, p. 176].[2]

The purpose of this paper is to provide insight into the interpretation of what constitutes discriminatory pricing practices and to examine the motives for discriminatory behavior in the food industry. It is hoped that the article will provide a basis for placing the concept of price discrimination in a broader context than is traditional in economic theory.

Problem

Although economists go to considerable lengths to theoretically distinguish among the various degrees of price discrimination [15, p. 279; 16, p. 179], there has been little analysis of the role price discrimination plays

---

[1] Landmark Supreme Court decisions include rulings against major pie baking companies for giving discriminatory allowances to purchasers of pies [19], geographic discriminatory allowances by brewers [7], discriminatory allowances by sellers of salt to grocery retailers [10], private label discriminatory allowances in evaporated milk [8], and unjustifiable quantity discount differentials in fluid milk distribution [18].

[2] Nine of these complaints were issued against dairy processors, six against processors of fruits and vegetables, seven against bakery companies; ten were other food industry complaints. In addition, 155 complaints against food concerns were based on sham brokerage payments [14, pp. 176–177].

R. E. SCHNEIDAU *is associate professor of agricultural economics and* RONALD D. KNUTSON *is assistant professor of agricultural economics at Purdue University.*

in the competitive process. To many people, the charging of discriminatory prices is an undesirable practice because it is associated with monopoly power, market exploitation, and income redistribution [6]. Others have found that the evolution of discriminatory pricing practices is an integral part of our competitive system and, as such, discriminatory prices are not undesirable unless they are stable or permanent in nature [1]. The latter view recognizes that the essence of competition is a search by business managers for the most profitable sales opportunities.

It is the exploratory hypothesis of this article that this conflict with respect to the probable effect of discriminatory pricing is related: (1) to the difference between lawyers and economists as to what constitutes discriminatory pricing, and (2) to a lack of recognition of the motives for discriminatory pricing.

Price Discrimination Defined

There is a distinct difference as to what constitutes price discrimination in the legal sense and in the economic sense. Economists consider price discrimination to exist when price differentials cannot be justified by cost differentials, or when prices are the same but costs are different. It follows that price discrimination ". . . is rigorously defined as a difference in profit earned by one customer as against another" [1, p. 223].

The Robinson-Patman Act is concerned only with price differentials not based on costs. Whereas economic price discrimination knows no geographic bounds, price discrimination to the legal profession applies only to sellers who are in competition with each other. The law views price discrimination as being an unfair trade practice, designed to reduce competition. The law does, however, have three major exceptions: (1) the product must be of like grade and quality; (2) it must be determined that the discrimination may injure competition or tend to create a monopoly, or injure, destroy, or prevent competition with any person who grants or knowingly receives the benefits of the discrimination, or with customers of either of them; (3) discrimination may be practiced when it is done to meet competition [17].

It follows that the legal definition is considerably narrower than the economic definition. Furthermore, the normative implications of the competitive behavior of firms in a market are considerably different. Thus, the economist's judgment of whether competition has been impaired by discriminatory practices will likely be at odds with that of the lawyer. For example, while the Robinson-Patman lawyer may consider a pricing system under which prices are stable and price differentials among buyers do not exist to be functioning well, an economist would consider such a situation indicative of monopoly practices. Indeed, the existence of discrimination may imply that the competitive process is functioning, while under the

Robinson-Patman definition discrimination may be interpreted as detrimental to competition. In a recent Supreme Court decision, three national pie bakers were convicted of illegal discrimination when they attempted to enter, by discriminatory pricing, a relatively isolated independent pie baker's market. Prior to the discrimination, the independent enjoyed a near monopoly position in the market [19].

The conflict becomes even more apparent when it is realized that under concentrated oligopoly a price adjustment in response to a cost decrease may not occur without a discriminatory price concession [11, p. 160]. Furthermore, the argument can be made that production of given products might not occur if price discrimination could not take place [15, p. 203].

Though economic theory is adequate to explain the role and implications of price discrimination, its application is frequently restricted to a single product, multiple market case [6, p. 179]. The classical example is a situation under which demand elasticities are different in two markets. The firm attempts to maximize profits by limiting output in the more inelastic market and casting the surplus off into the more elastic market. A variation of this theme exists when profits are maximized by segmenting the demand in a given market by the use to which a given product may be put. Of course, a market may be segmented simply because different customers are able and willing to pay different prices.

This view of price discrimination has caused economists to concentrate on the static optimum prices and quantities resulting from a given market situation. They thereby avoid recognition of the role of price discrimination in disequilibrium.

Motives for Price Discrimination

While some economists have studied methods of price discrimination [12], little attention has been given to short-run dynamic motives underlying the use of these methods. These motives are central to the ultimate effects of price discrimination. It is, of course, recognized that the long-run motive for price discrimination is profit maximization or growth. The effects of the short-run motive may be quite independent of the long-run profit maximum.

Market entry

Price discrimination is one of the primary means of obtaining market entrance. A food processor may give a retailer a special discriminatory price concession in order to penetrate a new market. It can be assumed that the new market will, over time, yield the processor a net profit. In the short run, however, there may be no attempt to maximize profits, no attempt to segment the market, and no attempt to gain advantage through differences in demand elasticities. Several techniques may be used to accomplish the entry motive, depending upon the economic organization of the market and the anticipated response of rivals. Whatever the technique used—price cutting, rebates, etc.—certainly, price discrimination in a legal and economic sense has taken place. After entry has been accomplished, it can hardly be inferred either from a short- or long-run competitive standpoint, that market entry discrimination is undesirable, unless accompanied by an intent to monopolize.

Improving market position

Discrimination is frequently used to expand sales within a market after market entry has been accomplished. Such discrimination may be motivated by a desire to increase sales, and thereby utilize unused plant capacity, or by a desire to gain market power. If motivated only by the desire to utilize unused capacity, the economic effect is not necessarily undesirable. Here again, in the short run, little use may be made of classical considerations motivating price discrimination.

Maintaining market position

In a dynamic economy, we are ever witnessing changing competitive structures and conditions within markets which dictate price changes. A study of pricing in oligopolistically structured fluid milk markets revealed that, through time, special discriminatory concessions were given to large volume preferred customers. These concessions eventually spread across the market, resulting in an overt price change. Distributors stated that discrimination was an essential competitive tool in their markets for accomplishing price change and maintaining sales [11, p. 160].

Firms may also discriminate in price to maintain product line sales. Price discrimination may occur when attempts are made to maximize profits for the blend of products sold. For any individual product, price differentials not based on cost exist for different purchasers. For example, consider a meat packer producing 20 major closely related meat products. The packer gives retailer X a discriminatory allowance for a product such as ham—a good grocery special. At the same time the packer gives a discriminatory allowance on bacon to retailer Y—a competitor of X. For both X and Y the packer attempts to make up for the discriminatory allowance on the other 19 meat products, so that the blend price and ultimate profit are equal for both retailers. Such a sales strategy complements the retailer's pricing strategy and therefore helps the packer to maintain sales on his total product line.

Price discrimination in the sense of maintaining market position may also be used to discourage market entry. A firm may maintain lower prices in one market than in another to discourage competitors from attempting market entrance. Although such discrimination may constitute a barrier to entry, one cannot a priori say that the market results would be more or less desirable than without discrimination.

Price discrimination to discourage entry is, of course, closely related to discrimination motivated by the need to meet competition. This exception, as indicated previously, is included in the Robinson-Patman Act.

Conclusions

It is apparent that price discrimination is an important short-run competitive tool in the food industry. Whether price discrimination has a competition enhancing or suppressing effect is largely a function of the motives for the discrimination and the length of time the discrimination exists in the market. Since the same method or technique of discrimination may be utilized for entirely different motives, it is the motive that is important in determining the effect of discrimination, *not* the technique. While economists have largely neglected the short-run role of price discrimination, the law appears to incorrectly assume that a primary motive for price discrimination is monopoly and, thus, that price discrimination has little place in the competitive market. One can, however, argue that the distinction made here is moot, since the standard of legality under the Robinson-Patman Act is a lessening of competition. Yet cases in the food industry, such as *Utah Pie,* indicated that the court tends to confuse injury or lessening of competition with injury to competitors, whereas injury to competitors is a normal and expected part of our competitive system. Our price discrimination legislation, in certain cases, appears to be stifling rather than stimulating competition in the food industries.

Consumer Attitudes Toward Milk Substitutes

ROBERT C. ANGUS AND J. WARREN STULL

THE dairy industry is confronted with the encroachment of substitute milks into the fluid market. These products are new in terms of market availability, even though the technical development took place in the fifties. Marketing substitute milks introduces the butter-margarine controversy in a new form. Substitute milks have been sold at lower prices than regular milk because butterfat has been replaced by relatively low cost vegetable oils. The product is available in approximately 20 states and sales are expanding. The rapid growth in the relative market share of filled milk in Arizona, to 10 percent of Class I producer milk since its introduction in October 1966, has drawn the attention of those people particularly concerned with evaluating the competitive potential of fluid milk substitutes.

The purpose of this paper is to present the results of a study of factors that may explain the acceptance of filled milk in terms of consumer attitudes and, alternatively, in terms of the different characteristics of consumers and nonconsumers of filled milk. The results of our study are compared with a study made by the Milk Industry Foundation [1]. These two studies were completely independent; the investigators had no knowledge of the other until the field work was finished.

Information was obtained on consumption, price, and place of purchase for 56 food products. Respondent households were selected at random from the Phoenix area during June 1968. Attitudes toward milk products were investigated by using 30 polar statements with a seven-unit intensity scale. To facilitate discussion, these results have been divided into three categories: (1) product use, (2) consumer characterics, and (3) nutritive characteristics.

Product Use

Respondents were less familiar with imitation milk than with whole milk. Of those questioned, nearly half had never heard of imitation milk. Six times as many families used milk frequently as those who used imitation milk often. A ratio of 3:1 was found between those who never used imitation milk and families that never used regular milk.

Families that purchased substitutes the previous week consumed an average of 10.9 quarts of milk-type beverage per week, 4.9 quarts of regular milk, and 6.0 quarts of substitutes. Those families who did not purchase

---

ROBERT C. ANGUS *is professor of agricultural economics and* J. WARREN STULL *is professor of dairy science at The University of Arizona.*

substitutes "last" week consumed a total of 10.1 quarts of milk per week.

The MIF study reported weekly household consumption of whole milk, other milk, and substitutes as 9.26 quarts. This figure includes .75 quarts of substitutes. Nonusers of substitutes consumed 8.96 quarts per week while substitute users had a milk-type beverage consumption of 13.98 quarts, composed of 4.5 quarts of whole milk, 1.83 quarts of other milk, and 7.65 quarts of substitutes.

Milk consumption figures from the two studies are in close agreement. The proportion of total milk beverage consumption accounted for by substitutes for regular users was 54.7 percent in the MIF study, 55.1 percent in the Arizona work. Less regular milk is consumed by families who purchase substitutes. The difference was statistically significant.

A key toward evaluating potential market acceptance of substitute products may be found in the volume sold in Arizona. At present, about 10 percent of the Class I producer milk is filled milk products. This proportion has been stable since July 1968.

Price comparisons for the Phoenix area found imitation milk selling for 39 to 43 cents per half gallon during June 1968. Regular milk was priced from 53 to 56 cents. The MIF study reports a seven- to nine-cent spread between these prices for July 1968.

Consumer Characteristics

Chi-square tests for independence of samples were used to examine the polar statements related to consumer characteristics.

The attitude proposition, "Not liked by children . . . Liked by children," resulted in a 7:1 ratio between imitation milk and regular milk on the "not liked" side. The ratio was 4:1 in favor of whole milk on the "liked" side.

Frequencies for the "Liked by adults . . . Not liked by adults" question pointed to a preference for regular whole milk. Imitation milk was liked by the entire family for only 14 percent of those interviewed.

Two questions dealt with sex differences via the "Women's drink . . . Men's drink," "Boy's drink . . . Girl's drink" scales. Imitation milk is considered by many to be more a woman's beverage. However, the "boy-girl" scale did not reveal significantly different frequencies. One explanation is that respondents thought imitation milk had fewer calories, was watery, and was for weight watchers. Thus, the imitation beverage may have more appeal for women than for girls who would have less serious calorie control problems.

The responses on "For company . . . Not for company" indicated regular milk was the drink to be served guests. One explanation is that imitation milk may be thought of as an inferior product. Regular milk was preferred for personal use.

The next step in the analysis consisted of an examination of the difference between families who purchased imitation milk last week and those who did not. This comparison includes the following factors: (1) education of homemaker; (2) disposable family income; (3) family expenditure for food eaten away from home; (4) size of household; (5) age of homemaker.

The average homemaker in families who purchased imitation milk had significantly more education than her counterpart. The difference was very small; imitation milk users completed one trimester while nonusers had four years of high school and no college.

The disposable family income for users and nonusers was not significantly different. The nonuser group averaged $7892 opposed to $7929 for users. Comparison of these income figures with those in the Milk Industry Foundation study is difficult because of the refusals and the wide income classifications in the MIF report. The MIF report concludes: "It is clear that substitutes are not being purchased primarily by the lower income groups." This conclusion is supported by the Arizona results.

No significant differences were found between the users and nonusers for family expenditures, for food eaten at home, or for expenditures for food eaten away from home.

The average size of household for purchasers of imitation milk was 4.6 persons versus 3.9 in the other group. This difference was not significant. The MIF study reported a higher proportion of larger families were regular users of milk substitutes than smaller families. The Arizona results agree, but again the difference was not significant at the five percent level.

No significant difference was found between the groups with respect to the age of the homemaker. Perhaps number of children under 16 years would have been a better variable.

Nutritive Characteristics

The ingredient characteristics of substitute milk beverages vary widely because standards of identity have not been adopted by most judicatory areas. The fat used in many products is based on hydrogenated vegetable oils. In some filled milks, isolated proteins are used in addition to unspecified amounts of nonfat milk. Likewise, there is variation in fortifying these beverages with minerals and vitamins [2].

Questions dealing with vitamins, calories, general nutritive value, protein, and calcium were included so that consumer knowledge could be compared with product characteristics. Responses relating to caloric content were particularly interesting. Seven times as many indicated imitation was low in calories as compared with regular milk. This opinion is not supported in fact. Filled milk has approximately the same fat and nonfat content. This result is supported by the MIF study where 63.9 percent of occasional users of milk substitutes believed these had fewer calories than regular milk. Regular milk was considered to be less watery or richer and more stylish. Families frequently pointed out a greater uniformity in the quality of regular milk. The response to "For weight watchers . . . For thin people" showed that the imitation product was thought of as a weight watchers beverage. Consumers identify the substitute with diet type or low fat beverages.

The protein question resulted in high ratings for regular fluid milk. Consumers are generally aware of the relatively high calcium content of whole milk. In reality, filled milks have the same protein and calcium content as whole milk, provided the nonfat solids proportion is equivalent.

The preceding analysis was based on the entire sample of users and nonusers of imitation milk. The breakdown of contingency tables has been extended to compare attitudes toward imitation milk by those who had purchased the product last week and those who had not. There were no significant differences between purchasers and nonpurchasers of imitation milk in their attitudes toward product content of vitamins, calories, protein, calcium, and general nutritional value. Nor were there any significant differences between imitation milk purchasers and nonpurchasers in their attitudes toward regular milk with respect to content of vitamins, calories, and protein. In summary, both groups were equally well informed and equally confused about regular and imitation products.

Conclusions

Attempts to explain why consumers ranked imitation milk and whole milk as they did verge on speculation. However, one must note the attitudes that do not conform to reality. The major one was the low evaluation for caloric content of imitation milk, which led to ranking it as a diet product . Second, regular whole milk has a "good" and "wholesome" image, a factor which may have led families to answer favorably for regular milk even though they had little or no knowledge on a specific question.

The University of Arizona research and MIF work agree closely. The real question deals with directions for additional investigation. Is our information base good enough to form market policy?

A naive multiple regression model was constructed with milk consumption as a dependent variable and a set of quantifiable demographic variables as independent variables. The coefficient of multiple determination (R^2) was .397. The significant variables were as follows: education of homemaker, a negative relationship expenditures for food eaten at home and away from home, a positive relation; and number of persons in the household, a positive relation. Disposable family income and the age of the homemaker were not significant. Additional independent variables can be added from the data. One example would be the number of family members under 16 years of age. Intercorrelations among independent variables are a serious problem in this type of analysis.

The point in discussing this regression analysis is that it highlights the problems for researchers. The real problem for researchers is identifying the relevant variables that are related to milk and substitute milk consumption.

Hidden Consumer Motives in Supermarket Selection

R. W. SKINNER

THE structure of the retail food industry has undergone significant changes since the Korean War period. At that time there were three major groups in the industry. Today there are only two significant groups, the corporate chains and the affiliated independents. The latter behave much as corporate chains in that the stores operate with common management or supervision. This fact alone accounts for much of the attention and concern of many in our economy about the competitive behavior of food distribution firms.

This changing structure has resulted in increased competition among supermarkets in non-price competitive tactics such as advertising, services, customer conveniences, etc. There is little evidence to support the theory that consumers actually demand or are influenced by many of the customer conveniences that retailers provide. The primary objective of the research reported here was to identify and define the basic consumer motives in selecting a supermarket. With this new insight, it will be possible for the retail food industry and the economist or marketing theorist to better assess the value or importance of the competitive tactics being used to attract consumers to a given supermarket.

Study Description

A sample of 300 consumers was randomly selected from the north-central part of Franklin County (Columbus), Ohio. This area was selected because of its diversity of income and education levels and fair representation of ethnic groups. This area is well represented by all the retail food firms that operate in the central Ohio market.

Annual incomes for the families of the sample ranged from less than $2,000 to over $15,000, with a median income of approximately $7,500. Educational level of the household head ranged from some grade school to completion of graduate work. The median education for the sample was slightly more than 12 years of schooling. Eighty percent of the respondents ranged from 25 to 54 years of age.

The questionnaire used in this study was in three parts: Part I, shopping habits of each respondent; Part II, a self-administered section in which the respondent rated 87 motivational statements related to supermarket shopping; and Part III, demographic data, such as income and ed-

---

R. W. SKINNER *is assistant professor of marketing at Kent State University.*

ucation of each respondent. The 87 motivational statements were the result of an analysis of previous studies and "brainstorming" with a group of food industry leaders. An effort was made to include all possible statements that might be part of the individual consumer decision-making process; these were reduced to 87 after pretesting in the Cincinnati market. Arranged in alphabetical order, the statements were rated separately by respondents on a scale from 1 to 7 (the higher the number, the greater the importance to the consumer in selecting a supermarket). A typical statement was worded: "Express checkout is available."

The Analysis

Through factor analysis, the 87 statements were reduced and simplified to eight basic motivational factors. Identification of each factor was based upon the factor loadings or correlations of each statement with the isolated factor. The square of the loadings is similar to r^2 in correlation analysis. Only loadings of .40 or above were included when identifying the factors in the study. Once the loadings or the individual statements were obtained for each factor, each was identified and named. The name given to the factor represents the statements with the significant loadings (.40 or above) on the factor. A summary of the eight factors with key identifying statements follows:

Factor A: *A Pleasant Shopping Experience* (14.3)

Clerks are friendly and helpful	.77	Clean shopping carts	.65
Shelves are well stocked	.75	Manager is friendly	.65
Store is clean and neat	.74	Plenty of parking space	.64
Floors are clean	.71	Easy access to/from parking lot	.63
Wide selection of foods	.69	Aisles are wide	.63
Fast checkout service	.68	Checkout girls are friendly	.60
Arrangement allows easy shopping	.67		

Factor B: *Prices* (6.0)

Low fresh meat prices	.75	Meat special regularly featured	.61
Low everyday prices on groceries	.74	Low sugar prices	.59
Low prices on canned goods	.73	Good weekly low price specials	.57
Fresh fruit and vegetable prices considered low	.64		

Factor C: *Social Influences* (5.8)

Store frequented by young housewives	.82	T.V. advertising conducted	.55
Store frequented by all age groups	.77	Friends and neighbors shop where I do	.47
Store is busy (many people shop there)	.70		

Factor D: *Near Other Services* (5.6)

Near group of stores	.81	Near drugstore	.69
Near ten cent store	.75	In a shopping center	.67
Near bank	.73	Near service station	.64

Factor E: *Meats* (5.5)

Tender meat is sold	.78	Wide selection of meat	.61
Fresh bright appearing meat	.77	Meat is free of excess fat	.55
High-quality meat	.72		

Factor F: *Advertising* (4.1)

Ads are easily read	.64	Advertised specials always available	.54
Ads have friendly tone	.64		

Factor G: *Convenience* (2.8)

Packaged meats offered	.67	Open weekday evenings	.40
Delicatessen foods are available	.50	Open Sundays	.40
Fruits and vegetables prepackaged	.47		

Factor H: *Location* (2.3)

Within one mile of your residence	.71	Within walking distance	.67

The percent of total variance among all statements that is explained by each factor is shown in parenthesis. While eight factors explain only 46.4 percent of the total variance, the more important factors that influence the consumer in selecting a supermarket have been identified.

The Results

The analysis clearly revealed some new dimensions to be considered regarding consumer motives in supermarket selection. Many of these factors have been hidden or beyond the conceptual view of the food industry and marketing people. The food industry has not been "tuned in" to the consumer. This was the finding when 186 members of the food industry at the Ohio Food Distribution Conference responded to Part II of the questionnaire. The conference participants were retailers, food manufacturer representatives, brokers, and food marketing educators. They were asked to rate the 87 statements as they thought the consumer would rate them. In summary, the identified factors for the food industry personnel are compared with the factors isolated by consumers in Table 1.

Implications

The factor *A Pleasant Shopping Experience* was not isolated as a motivational factor in supermarket selection by the food industry. The consumers view this factor as consisting of six variables: friendliness, selection, cleanliness, parking, fast checkout service, and ease of shopping. As a result of this finding, it is logical to conclude that, as the presence of these variables increase (in a positive way), the probability that the shopping trip will be pleasant increases. All are variables that can cause irritation to the consumer from the time she enters the parking lot until she leaves the checkout. These are variables that are largely a function of store management.

The factor *Friendliness and Perishables* was isolated by food industry

Table 1. Consumer motivational factors in supermarket selections

Factors	Contribution to total variance	
	Consumers	Food industry
	percent	
A pleasant shopping experience	14.3	x
Prices	6.0	6.1
Social influences	5.8	4.9
Near other services	5.6	5.3
Meats	5.5	x
Advertising	4.1	3.8
Conveniences	2.8	3.2
Location	2.3	x
Friendliness and perishables	x	9.4
Front-end	x	3.4
Modern appearances	x	3.3
Trading stamps	x	2.7

personnel. There are high loadings on this factor related to friendliness, meats, and produce. Recall that consumers considered friendliness as part of *A Pleasant Shopping Experience* and considered *Meats* as a separate motivational factor. The food industry also isolated two additional factors identified as *Front-End* and *Modern Appearance.* These are factors that food industry trade publications have given much attention to during recent years, which may explain why they were identified by the industry but not by consumers.

Observe that *Location* was not identified as a separate factor by food industry personnel; instead, they combined *Near Other Services* and *Location* as one motivational factor, while consumers separated these into two factors. Thus, consumers think of a store as being near their place of residence or near other stores. The recent trend of the food industry to establish neighborhood free standing stores suggests that they have become alert to this distinction.

It is significant that the food industry identified *Trading Stamps* as a motivational factor while consumers did not. The evidence suggests that trading stamps are not an important motivational factor to consumers in supermarket selection.

The eight factors identified by consumers provide the retail food industry with new understanding of the consumer and what influences her in her selection of a food store. These isolated factors may be categorized as internal and external factors, as follows:

Internal (within the store)

A Pleasant Shopping Experience
Meats
Prices
Conveniences

External (outside the store)
- Advertising
- Location
- Near Other Services
- Social Influences

Looking to the future, it may well be particularly meaningful to train store managers in terms of the four basic motivational factors classified as internal. The store manager who makes greater efforts to insure the consumer a pleasant shopping experience, better meats, lower prices, and improved conveniences will likely experience increased volume which, in turn, should result in greater profits.

A Decision Model for Continuous Sequence Production Processes of Variable Length: An Application to Hog Marketing*

JOHN E. IKERD AND ALVIN R. SCHUPP

PROFIT maximization over time is the goal of economic production regardless of whether the production process is of fixed or variable length. The classical criteria for profit maximization are consistent with maximization over time when the production process is of fixed length. Variable length production processes, as encountered in livestock feeding, require somewhat different criteria from those given by the classical theory of the firm. The length of a process can affect both production costs and revenues (e.g., length of feeding of livestock). When there is a time lag between the end of one variable length process and the beginning of another, profit maximization is achieved by extending the process so long as the extension results in additions to revenue greater than or equal to additions to cost.

When there is no time lag between the end of one variable length production process and the beginning of another (i.e., continuous sequence production), the problem is to maximize profits per unit of time rather than from any one production process [1, pp. 162–170]. Few marketing decision models have been developed for this type production. Faris [2] develops a set of criteria for the specific case of a continuous sequence of two production periods. This paper develops the criteria for the general case of a continuous sequence of *m* variable length periods and applies it to the hog producer.

The producer using this model compares the discounted expected value of marketing his hogs in the present time period with the discounted expected value of marketing one time period into the future. If a producer markets his hogs in the present time period, he has excluded some of the possibilities of future marketings, in terms of both prices and market weights, that would have been open to him had he chosen to sell in the fol-

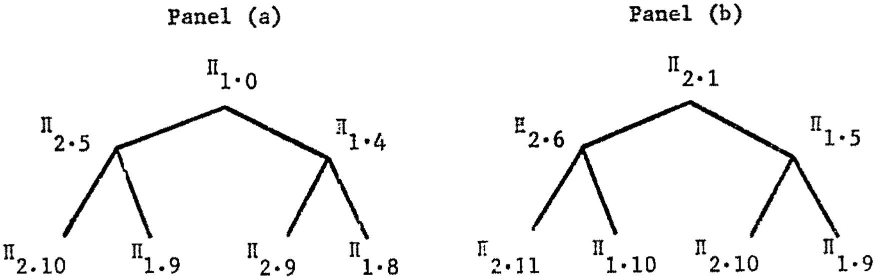
Figure 1. Marketing possibilities for a two-period planning horizon[a]



[a] Explanation of symbols:

$\Pi_{1\cdot t}$ = Possible profit (revenue minus costs) per day from hogs fed more than 4 but less than 5 months and marketed t months from the present.

$\Pi_{2\cdot t}$ = Possible profit (revenue minus costs) per day from hogs fed more than 5 but less than 6 months and marketed t months from the present.

lowing time period. But if he decides to hold his hogs one more period, he has excluded some possibilities that would have been open had he chosen to market in the present time period. Under conditions of uncertainty, the goal then is to make the decision in such a way as to leave open the most profitable set of possibilities considering both present and future marketings.

Assume that the possibilities open to the decision maker who has a lot of 4-month fed hogs are to sell now or to sell in the next month. Figure 1 shows the expected net returns possible (within a two period planning horizon) for each of the alternatives. Panel (a) shows the possibilities open to the producer if he chooses to market in the present month, and Panel (b) shows similar possibilities for marketing in the following month.

By appropriately weighting and discounting the expected profits from each set of possibilities, the alternative promising the largest expected returns can be determined. Downward trending prices would favor the decision to sell in the present time period resulting in lighter market weights. On the other hand, upward trending prices would favor the decision to hold the hogs longer resulting in heavier market weights.

The model assumes the following:

(1) The individual producer desires to maximize net expected profits from his planning horizon.
(2) The producer chooses initially to market in one month (4-month hogs; month 0) or the succeeding month (5-month hogs; month 1).
(3) Replacement feeder pigs are available when required to keep facilities efficiently utilized.
(4) Producers marginal cost curves rise with increasing weight.
(5) The production cycle encompasses a 4 or a 5 month period.
(6) Expected profits per day within a given month are relatively constant.

(7) Homogeneous initial weight for feeder pigs and uniform weight gain over the production period for all animals within the lot.

(8) Producer has access to reliable profit estimates for future marketings.

The relationship showing expected returns from the two sets of possibilities (shown on the diagram), appropriately weighted and discounted, can be expressed in two equations which define the general m period decision model:

$$E(V_0) = \sum_{p=0}^{m} \sum_{t=4^p}^{4p+p} \frac{1}{(m+1)2^p} \left[\left(\binom{p-1}{k} \left(\frac{\Pi_{1 \cdot t}}{(1+r+z)^t} \right) \right) + \left(\binom{p-1}{k-1} \left(\frac{\Pi_{2 \cdot t}}{(1+r+z)^t} \right) \right) \right]$$

$$E(V_1) = \sum_{p=0}^{m} \sum_{t=4^p}^{4p+p} \frac{1}{(m+1)2^p} \left[\left(\binom{p-1}{k} \left(\frac{\Pi_{1 \cdot t+1}}{(1+r+z)^{t+1}} \right) \right) + \left(\binom{p-1}{k-1} \left(\frac{\Pi_{2 \cdot t+1}}{(1+r+z)^{t+1}} \right) \right) \right]$$

where

t = month into the future where t can assume any integer value 0, 1, 2, 3, . . .

r = interest rate for discounting future returns to the present.

z = uncertainty premium or probability of a significantly incorrect estimate of profit.

$m+1$ = number of feeding periods in the planning horizon.

p = future feeding periods with p assuming the values of 0 for the present period and 1, 2, 3, $\cdots m$ for feeding periods into the future.

$k = 0, 1, 2, \cdots p$ as $t = (4p), (4p+1), (4p+2), \cdots (4p+p)$.

$$\binom{p-1}{k}^1 = \left[\begin{array}{l} 1, p = k = 0 \\ 0, k = p, p > 0 \\ \binom{p-1}{k}, p > 0, 0 < k < p \end{array} \right. \qquad \binom{p-1}{k-1}^1 = \left[\begin{array}{l} 0, p = 0 \\ 0, k = 0 \\ \binom{p-1}{k-1}, p > 0, \\ \qquad 0 < k < p \end{array} \right.$$

$E(V_0)$ = expected value of planning horizon from marketing in present month.

$E(V_1)$ = Expected value of planning horizon from marketing one month in the future.

The factor 2^p gives the possible combinations of 4-or-5-month feeding periods leading to marketings of hogs in months $t(t=4p$ to $4p+p)$ from the pth feeding period. This holds true for $p=0,1,\cdots,m$. The factor $1/(1+r+z)^t$ discounts expected net profits for both the present value of future profits (r) and the decreasing reliability of profit estimates as time into the future increases (z). The symbol $\binom{p-1}{k}$ gives the number of combinations of 4- or 5-month feeding periods leading to the possible marketings of 4-month fed hogs in each of the $4p$ to $4p+p$ $(k=0,\cdots,p)$ months. The symbol $\binom{p-1}{k-1}$ gives the corresponding number of combinations leading to 5-month fed hogs marketable in the pth feeding period.[1] The factor $1/(m+1)2^p$ assigns equal weight to the 2^p possible combinations of 4- and 5-month periods leading to marketings in the pth period and maintains the sum of the weights equal to 1 for any value of m.

For model illustration purposes, assume computation of the expected value of marketing in the present month using a planning horizon of two feeding periods into the future. By substituting $(d)^t=(1+r+z)^t$ the expected value of marketing in the present month becomes:

$$E(V_0)=\left[1/3\ \Pi_{1\cdot 0}\right]+\left[1/6\ \frac{\Pi_{1\cdot 4}}{(d)^4}\right]+\left[1/6\ \frac{\Pi_{2\cdot 5}}{(d)^5}\right]+\left[1/12\ \frac{\Pi_{1\cdot 8}}{(d)^8}\right]$$
$$+\left[1/12\ \frac{\Pi_{2\cdot 9}}{(d)^9}\right]+\left[1/12\ \frac{\Pi_{1\cdot 9}}{(d)^9}\right]+\left[1/12\ \frac{\Pi_{2\cdot 10}}{(d)^{10}}\right]$$

The expected value of marketing one month in the future $[E(V_1)]$ would then be compared to this value to determine the month yielding the highest expected value.

A computer simulation program was developed and run to compare continuous sequences of fixed lengths (4 and 5 months) with the variable length model. Four-month fed hogs were assumed to weigh 220 pounds and to have production costs of \$15.00 per hundredweight. Five-month fed hogs were assumed to weigh 270 pounds and to have production costs of \$15.25. Hogs were priced using monthly price data for U. S. Grades 1–3 hogs during the 1956–67 period. Decisions were made at the appropriate 4- and 5-month intervals. The most profitable planning horizon using this set of data was found to be 6 periods. Profits were compared assuming a 6-period planning horizon and 400 hogs on feed at all times. Profits per month using the decision model were \$582.40 compared with \$551.45 per month for the continuous sequence of 4-month periods and \$374.62 per month for the sequence of 5-month periods.

The general decision model is adaptable or modifiable in several respects. The 2-month flexibility period was chosen for simplicity only; the model will accommodate any flexibility period by substituting the desired period for months. Variations of the model permit net revenue maximization by those with varying degrees of risk aversion as well as with differing abilities to predict future prices. The model is equally adaptable to study marketing decisions for other livestock, such as cattle and sheep.

---

[1] This is the normal combinatorial symbol where exceptions are defined for values of p and k for which the normal symbol would be undefined.

Implications

The model permits adjustments in the length of feeding in the present period that are brought on by expected price changes in the future. If prices in the medium-to-late planning horizon are expected to peak and begin to descend, the model will initially encourage longer feeding of each production cycle and then shorter feeding periods as the price peak is passed. This places more pork on the market at the expected peak prices (through heavier weights) while less pork is marketed as the expected price descent begins. Thus, the model will tend to encourage contracyclical production. If reliable and reasonably accurate estimates can be made of future prices for live hogs, it is hoped that the proposed model can work to smooth the cycle and stabilize production at profitable price levels for most producers.

A Game Theoretic Model for Farm Planning Under Uncertainty*

MAHFOUZ E. TADROS AND GEORGE L. CASLER

UNCERTAINTY has long been recognized as an important aspect of farm planning. It was only recently, however, that different approaches to the problem of uncertainty in farm planning have been suggested [2, 5, 6, 7, 9]. These approaches employed techniques such as dynamic programming, game theory, quadratic programming, simulation, and stochastic linear programming. The game approach suggested by McInerney [5] was the first attempt that we have found in the farm management literature to incorporate farm constraints in a game against nature. McInerney's model, however, provides solutions only for the Wald maximin criterion. Decision criteria other than the Wald maximin may be more appealing to some farmers. This paper presents a model that incorporates farm constraints in a game against nature in a different manner from that of McInerney's model. The proposed model enables a farmer to obtain solutions for the maximin criterion and other decision criteria.

The Model

Decision making under uncertainties in factors such as weather could be specified in the form of games against nature [4]. Thus, one can conceive of a farm planning problem as a farmer game against nature.

A game against nature has three basic components, states of nature, alternative courses of action (decision maker's strategies) and a payoff matrix. The proposed model is a game against nature; the elements of this game are specified in the following pages.

The states of nature for this game represent different possible combinations of gross margins of the farm activities (activities in the linear programming sense) which might occur in the planning period ahead. Thus, each state of nature is characterized by different production and price conditions. Let us assume n states of nature are possible in the next planning season, namely, $S_1, S_2 \cdots S_j \cdots, S_n$, where n is a finite number.

The farmer's strategies, for this game, are defined by various combinations of farm activities (farm plans). These farm plans are derived by linear programming. A deterministic linear programming model for planning farms is developed for this purpose:

---

* The comments of K. L. Robinson and B. F. Stanton on an earlier draft are sincerely appreciated.

MAHFOUZ E. TADROS *is research associate in agricultural economics and* GEORGE L. CASLER *is associate professor of agricultural economics at Cornell University.*

$$\text{Maximize} \quad \sum_{j=1}^{N} c_j x_j$$

$$\text{Subject to} \quad \sum_{j=1}^{N} a_{ij} x_j \leq b_i \qquad \text{for all } i \ (i = 1, 2, \cdots, M)$$

$$x_j \geq 0$$

where

c_j = the gross margin per unit of the jth activity, $(j = 1, 2, \cdots, N)$

x_j = the level of the jth activity, $(j = 1, 2, \cdots, N)$

b_i = the quantity of the ith resource (or activity constraint) available (or allowed) to the farm, $(i = 1, 2, \cdots, M)$

a_{ij} = the quantity of the ith resource (or activity constraint) required by one unit of the jth activity i.e. input—output coefficient, $(i = 1, 2, \cdots, M; j = 1, 2, \cdots, N)$.

To define a particular strategy for this game, let us assume that a given state of nature (say S_j) is going to prevail next season. The question then arises as to what combination of farm activities (farm plan) should the farmer adopt in order to maximize his returns. Our definition of a state of nature for the game model is the same as the objective function for the linear programming model (i.e. the gross margins of the farm activities). Thus, the gross margins associated with a given state of nature (say S_j) could be used as the objective function for the linear programming model. Solving this linear programming problem provides the farmer with an optimal farm plan for the S_j state of nature, if one exists. Let X_i denote that optimum farm plan where X_i is a vector of farm activities $(x_1, x_2, \cdots x_j, \cdots, x_n)$. This optimum combination of farm activities (X_i) is one of the strategies for the game model. Other strategies are defined for each state of nature in the same manner. Thus, n linear programming problems have to be solved to define the strategies for the game model. Let m designate the total number of defined strategies, where m is a finite number. A particular state of nature could have more than one optimal farm plan. It is also possible that a particular farm plan could be optimal for more than one state of nature. Therefore, the total number of strategies (m) could be greater than, equal to, or less than the total number of states of nature $(m \gtreqless n)$.

The payoff elements for the game are the values of the various strategies $(X_1, X_2, \cdots X_i, \cdots, X_m)$ under the different states of nature $(S_1, S_2, \cdots, S_j \cdots, S_n)$. Let o_{ij} represent the payoff (outcome) to the farmer if he plans strategy X_i and the S_j state of nature prevails, where X_i is optimal for S_j. This payoff (o_{ij}) is the value of the objective function that results from solving the linear programming problem using the gross margins of S_j. Now assume that the farmer had planned strategy X_i but S_k prevailed, where $k \leq n$ and $k \neq j$. The payoff to the farmer in this case is the value of X_i with the gross margins of the state S_k. Let this payoff be designated by o_{ik}, where o_{ik} could be greater than, equal to, or less than o_{ij} ($o_{ik} \gtreqless o_{ij}$). The same relation could hold for the gross margins of any farm activity in both states (S_k and S_j).

Let us formulate the payoff matrix for a special case of this game. It is assumed, for this special case, that each state of nature has only one optimal strategy and each strategy is optimal for only one state of nature. This assumption results in as many strategies as states of nature, i.e., $m = n$. Thus, the payoff matrix is a square matrix and could be presented as:

$$\begin{array}{r|lllll}
 & \multicolumn{5}{c}{\text{States of nature}} \\
 & S_1 & S_2 \cdots & S_j \cdots & S_k \cdots & S_n \\
\hline
X_1 & \boxed{o_{11}} & o_{12} \cdots & o_{1j} \cdots & o_{1k} \cdots & o_{1n} \\
X_2 & o_{21} & \boxed{o_{22}} \cdots & o_{2j} \cdots & o_{2k} \cdots & o_{2n} \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\text{Farmer's } \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\text{strategies } X_i & o_{i1} & o_{i2} \cdots & \boxed{o_{ii}} \cdots & o_{ik} \cdots & o_{in} \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
X_k & o_{k1} & o_{k2} \cdots & o_{kj} \cdots & \boxed{o_{kk}} \cdots & o_{kn} \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
X^m & o_{m1} & o_{m2} \cdots & o_{mj} \cdots & o_{mk} \cdots & \boxed{o_{mn}}
\end{array}$$

Each of the diagonal elements of this payoff matrix represents the highest payoff that the farmer could obtain if the state of nature corresponding to a given diagonal element prevails. This implies that none of the strategies defined is dominated by any other strategy i.e., none of the rows is an inferior row. This feature holds for the general case (i.e., $m \gtreqless n$), except under the unlikely situation where there exist more than one optimal plan for a particular state, and one of those plans is dominated by another plan also optimal for that state.

Once the payoff matrix is formulated, the farmer may select a farm plan (or a linear combination of two or more farm plans) that corresponds best with his objectives, attitudes and financial obligations. Various decision criteria, including the Wald maximin [4], Savage regret [4], Hurwicz [4], benefit [1], and Laplace [4], have been suggested to help the decision maker choose among his strategies. Each of these decision criteria implies different objectives or psychological characteristics of the decision maker. Both pure and mixed strategy solutions are allowed in this game. A mixed strategy solution specifies a linear combination of two or more strategies. Mixed strategies could be derived by linear programming [3].

The framework of the proposed model provides the farmer with useful means for identifying the main components of this decision problem. It also allows for a meaningful consideration of the pros and cons of alternative farm plans. In addition, the game approach can be easily rationalized and its results can be presented in a simple format. The proposed model also has the advantage of using a standard linear programming computer code that is readily available.

The proposed model has been applied to a cash crop farm in New York State [8]. Both yield (or technical) uncertainty and price uncertainty were considered. Twenty-two states of nature were identified for the game. The gross margins of these states were derived from time series data. Solutions were derived for seven decision criteria. It was noted that the maximin solution derived by the model proposed in this paper and that obtained by McInerney's model [5] were exactly the same for this farm. This, however, should not imply that the two models would result in the same solution in other cases.

Perhaps a crucial part of this model is the definition and specification of the states of nature. If the states of nature are defined so that their probabilities can be determined, the Bayesian approach could be incorporated in the model.

Application of Linear Programming to Individual Farm Planning

DONALD C. HUFFMAN AND LYNN A. STANTON

The Problem

FARMERS, Farm Management Extension personnel, and farm organization leaders are interested in the possibility of using computers for assisting in making management decisions for individual farm situations. Private farm management firms tend to be more interested in providing a farm management service while some of the Extension personnel are more interested in the service as a catalyst for educational programs with farmers. The relatively high cost of programming a resource situation and the difficulty of defining precision input-output relationships have retarded the adoption of these techniques for extension work with farmers.

A research study at Louisiana State University was designed to explore the similarities in farm organization when short cuts were taken in the linear programming process by (1) using standardized input-output coefficients, such as would be available in a data bank; and (2) by using a simplified programming matrix, which included only key resource restraints and production activities based on the experience of professional farm management specialists. A second phase was designed to evaluate the range of farm organizations for which income levels approximated that obtained with optimal organization. The primary purpose was to determine whether relatively low cost linear programming solutions were sufficiently accurate to be offered as a management service to farmers.

We began with the assumption that a detailed linear programming model utilizing the farmer's input-output data is both too costly and too time consuming to have widespread acceptability among farmers. A second limitation of this procedure is the lack of sufficient data to estimate many of these relationships for the individual farm.

If we can obtain basically the same farm organization using "standards" or "norms" that we get with the "best estimate," the cost per farm could be reduced considerably. Given a set of structural models, a data bank, the primary resource restraints and potential production activities, relatively low cost personnel, using routine procedures, could select the appropriate model and input-output coefficients.

A reduced size model would require the services of trained specialists

familiar with the farm situation to structure the production alternatives and resource restraints. However, the planning job could be performed in no more time than would normally be spent in "budgeting" a farm situation. A larger number of variations in the plan could be considered than would be likely with budgeting procedures. This type model could improve the effectiveness of the farm management specialist, if satisfactory solutions can be obtained at a reasonable cost.

If a range of alternative organizations exist which provide income levels near that achieved by the optimum organization, the less precise techniques may provide acceptable organizations even though they may not be "the optimum" organization. A range of near optimum organizations may be of more importance than identifying the optimum. This has particular relevance when considering managerial preferences.

The Procedures

Three farm resource situations were selected for case studies, representing varying degrees of complexity in terms of feasible production alternatives. A detailed matrix (approximtely 60 × 60) was developed for each farm situation. The matrix structure and coefficients included were developed from data obtained from the farm managers during a number of intensive interviews. The solutions for these models were then used as the best estimate of the optimum organization for each of the respective farm situations.

A second matrix (structurally the same as the first) was developed for each farm situation using the type input-output coefficients that could be maintained in a data bank.

A third matrix (approximately 20 × 20, or less) was developed for each farm situation. Resource restraints and production alternatives were more aggregative and less inclusive than for the detailed models. A priori decisions by the farm planner provided the basis for eliminating production alternatives, options within alternatives, and resource restraints. (This model is also adapted to standardized coefficients.)

The coefficients for the standardized detailed model and both the coefficients and structure of the reduced size model were probably more tailored to the individual farm situation than would be expected within the framework of a farm planning service, because of the bias of a priori knowledge acquired by the farm planner during the intensive interviews with the farm managers.

A number of modifications of resource restraints and production activities were imposed upon each of the "best estimate" matrices to develop a range of alternative organizations for each farm resource situation. This was done to evaluate the degree of accuracy for acceptable solutions.

Results

The farm organizations determined using standardized coefficients deviated considerably from those determined using the best estimate coefficients. They deviated in terms of enterprises included, quantitities of enterprise included, and production practices within enterprises. In general, these solutions were unacceptable for all resource situations.

A superficial inspection of the results from the reduced size models suggested considerable similarity in organization to that obtained with the detailed best estimate model. However, the production practices assumed in the smaller model were not consistent with those selected in the detailed model, the choice of feed grains to produce was not consistent, and the mix of feed grains and soybeans included was not consistent. The choice of combinations of these enterprises was highly interrelated with the production practices utilized. The deviations were greater for the more complex resource situations. Thus, the solutions from these models were unacceptable in terms of similarity in farm organization.

Changes occurring in farm organization due to changes in the resource restraints imposed on the model were predictable. Approximately 30 variations in the restraints were imposed on the model for the most complex resource situation. These included some rather severe limitations simulating managerial preference. Approximately 20 percent of the solutions yielded net income levels within 6 percent of the income for the optimum and about 40 percent yielded net income levels within 12 percent. About 80 percent of the solutions were within 20 percent. A wide range of organizations were included within both the 6 percent and 12 percent ranges. The most drastic reductions in income were caused by eliminating or imposing arbitrary maximum limits on high value enterprises.

Implications

The results of this study provide little optimism for the direct use of linear programming as a farm management service. The solutions obtained from the reduced size matrix are probably neither more nor less acceptable than budgeing solutions. A fairly wide range of alternatives appears to be acceptable by a net income criterion, considering our limitations for accuracy in coefficient determination. The question remains: "Will the benefits derived from utilizing 'optimum linear programming solutions' from a reduced size matrix in a farm management program justify the costs associated with providing a linear programming service to farmers?" The benefits will be greater if the farmer is provided a package of solutions for evaluation rather than a single optimum solution.

There is a note of optimism for indirect use of linear programming in farm planning. The manipulation of restraints on the more detailed models provided considerable insights into the factors affecting farm organization. There may be considerable merit in developing data banks (if sufficient stratification is provided) and using these to update a series of solutions for selected benchmark farm situations. A study of the results from a series of solutions can be a valuable aid in determining what alternatives to consider in a budget analysis for a particular farm situation, what factor(s) affect a particular choice, and the kind of effect the factor(s) have on a particular choice. This endeavor would be expensive, but we believe it could be justified if emphasis is to be placed on providing farmers with intensive assistance in management decisions.

Farm Capital and Credit Projections to 1980

EMANUEL MELICHAR

WITH the approach of a new decade, several projections of farm capital in 1980 have appeared. Conceptually, such long-run capital projections ought to be particularly useful to agencies that can influence the volume and terms of credit available to agriculture. For instance, availability of bank credit might be increased by developing secondary markets for farm loan paper, improving access of rural banks to discount facilities of the Federal Reserve Banks and Federal Intermediate Credit Banks, or promoting branch banking. Such efforts are more likely to be seriously pursued if greater future credit demands can be well documented.

Unfortunately, most capital studies have not served this purpose. Common shortcomings and omissions are discussed below, along with some thoughts that may help point the way to improved work. Throughout, one recently published projection is used simply to provide an empirical example of the considerations discussed, not because it is necessarily better or worse than other available projections.

Capital Stocks

The National Advisory Commission on Food and Fiber sponsored a study to "get the best possible estimate of the resources and farm structure needed to produce food and fiber in 1980" [1, p. iii]. From several projections of 1980 capital stocks made in that study, the Commission chose to present the "feed grain model" in which the 1980 stock of real estate, machinery, and livestock was projected at $275.6 billion "in 1965 dollars," up from $200.9 billion in 1965. This "suggests that the total value of capital employed in agriculture will increase by 35 to 40 percent in 1980" [2, p. 240].

As physical quantities of farm assets rose by only about 11 percent during the preceding 15 years of great agricultural change, this was an exciting projection. Thus, what a letdown to find that a unique concept of "1965 dollars" had been employed. The machinery and livestock projections did refer to physical quantities, but two-thirds of the projected gain in total capital reflected only the land price appreciation that would occur if projected increases in rents (in 1965 dollars) were capitalized into land prices at the 1965 capitalization rate. This partial estimate of land price

---

EMANUEL MELICHAR *is an economist in the Division of Research and Statistics at the Board of Governors of the Federal Reserve System, Washington, D.C.*

inflation was added to the projected real increases in machinery and livestock to get a total that represents—what?

If stability in physical real estate assets is projected—an expectation consistent with the relatively insignificant growth experienced since 1955—the adjusted 1980 projection for the three assets in 1965 prices totals $225.9 billion, an increase of only 12 percent during 1965–80 (Table 1, part B).

But a projection in truly real terms remains of limited value to those concerned with capital requirements and credit demands. In 1950, for example, how helpful would it have been to have had perfect foreknowledge of the 11 percent real increase that was to take place by 1965—but not to have known that current-dollar stocks would double and aggregate credit demands triple?

Table 1. Past and projected farm capital stocks (billions of dollars)

Type of asset	1950	1965	1980
A. Heady-Mayer "feed-grain model" projection for 1980			
Land and buildings			210.5
Machinery and equipment			43.3
Livestock inventories			21.7
			275.6
B. Actual values and adjusted Heady-Mayer projection (1965 dollars)			
Land and buildings	148.3	160.9	160.9
Machinery and equipment	18.4	25.5	43.3
Livestock inventories	12.2	14.5	21.7
	178.9	200.9	225.9
C. Actual values and adjusted Heady-Mayer projection (current dollars)			
Land and buildings	75.3	160.9	283.3
Machinery and equipment	12.2	25.5	62.7
Livestock inventories	12.9	14.5	21.7
	100.4	200.9	367.7

The general price level has on average been rising by 2 percent annually since 1950, further increases are generally expected, and several studies have indicated a proportional response in land prices. This prospective contribution to land price inflation might be added to the rent capitalization effect already in the model. Also, farm machinery prices have exhibited an average annual increase of 2.5 percent since 1950, and a continuation of this rate might be projected. With these crude but plausible price adjustments, projected 1980 current-dollar stock becomes $367.7 billion, up 83 percent from 1965 (Table 1, part C).

Capital Flows

Capital flows, rather than changes in stocks, constitute the capital requirements that must be financed and can lead to credit demands. Flows can be much different from the changes in stocks, if any, that accompany them. Flows may be defined as capital required for (1) replacement of buildings, land improvements, and machines that wear out or become obsolete; (2) physical additions to the stock of land, land improvements, buildings, machinery, livestock, stored crops, and working capital; and (3) transfer of real estate by sale rather than inheritance [3, p. 134].

USDA estimates provide annual data on all past capital flows except real estate transfers. But this data gap can be approximately filled by using new USDA data on the value of farms sold in 1965–67 plus some heroic assumptions, enabling complete capital flows to be estimated. Annual requirements fluctuated around $8 billion in the late 1950's and early 1960's but rose to $11 billion in 1965–67, as machine stocks were increased and land price inflation accelerated (Table 2).

Table 2. Average annual farm capital flows (billions of dollars)

Type of capital requirement	Estimated actual				Projected—feed grain model		
	1950–54	1955–59	1960–64	1965–67	1965–69	1970–74	1975–79
Gross capital expenditures:							
Machinery	3.1	2.8	3.2	4.6	5.1	7.0	9.4
Buildings, etc	1.5	1.4	1.3	1.3	1.3	1.3	1.4
To increase:							
Livestock inventory	.5	.1	.3	0	.4	.5	.5
Stored crop inventory	.1	.2	0	.4	.1	.1	.1
Working capital	.1	−.1	0	.3	.1	.2	.2
Real estate purchases	2.5	3.0	3.5	4.4	4.5	5.4	6.5
Total	7.8	7.4	8.3	11.0	11.5	14.4	18.1

Given a projection of farm capital stocks that shows its real and price inflation components, together with projected depreciation and real estate transfer rates, the implied capital flows can be derived. Capital flows under the adjusted feed grain model are estimated to rise to an annual average of $18.1 billion in 1975–79, up 118 percent from the average level 15 years earlier (Table 2).

Credit Demands

Projection of capital flows is but a first step toward estimation of credit demands, that is, of net changes in farm debt. Minimum further needs are

Table 3. Sources of capital (annual average billions of dollars)

	Estimated actual				Projected—feed grain model

(F) as percent of (C)	38	36	31	31	31	31	31
Sources—Model II							
(I) From total cash flow	6.8	6.0	5.7	6.7	6.7	8.1	9.6
(J) Increase in debt	1.0	1.4	2.6	4.3	4.8	6.3	8.5
(H) Capital requirements	7.8	7.4	8.3	11.0	11.5	14.4	18.1
(I) as percent of (E)	27	26	22	21	21	21	21

projections of farm income and of the relative distribution of capital financing among income, depreciation allowances, and debt—all consistent with the capital projection. Ideally, all projections would be the output of a model in which the capital, income, and savings equations are jointly developed. Here, a crude procedure will be used to illustrate the considerations involved and perhaps inspire more sophisticated future efforts.

First, depreciation allowances consistent with projected machinery and building stocks are calculated. In the adjusted feed grain model, allowances rise rapidly because of the large buildup in the real machine stock. Second, to project net farm income, we might assume that in the long run countervailing political forces will keep growth in real per farm income roughly parallel to growth in national real per capita income, which the National Planning Association has projected at 3.25 percent annually for 1965–80. If in addition the general price level rises by 2 percent and farm numbers decline by 3.3 percent annually, aggregate net farm income would advance by 1.84 percent yearly. Annual farm cash flow—the sum of depreciation allowances and net farm operator and landlord income—would then average $28.2 billion in 1975–79, compared with $21.5 billion in 1965–67 (Table 3, line C).

Next, how have capital flows been financed in recent years? We know the past increase in debt; by subtracting it from the estimated total capital outlays, we obtain a sum that we can regard as financed from farm

Table 4. Farm debt

	Estimated actual				Projected—feed grain model		
	1950–54	1955–59	1960–64	1965–69	1965–69	1970–74	1975–79

Projected—feed grain Model II					10.4	8.6	7.8

cash flow. On an average annual basis, capital flow requirements in 1965–67 were $11.0 billion and the increase in debt was $4.3 billion; thus $6.7 billion was financed from cash flow. This amount was 31 percent of farm cash flow of $21.5 billion.

Suppose that this rate of internal savings continues. Then in 1975–79, for example, 31 percent of farm cash flow, or $8.7 billion annually, would be applied toward total annual capital outlays of $18.1 billion. Therefore, the remaining annual outlays of $9.4 billion must be financed by increase in debt (Table 3, Model I).

Alternatively, perhaps farmers' nonfarm income should be included in cash flow (Table 3, line E). Similar calculations show that farmers have recently been applying about 21 percent of total cash flow toward capital requirements. If this savings rate is projected, and nonfarm income continues to rise at the 1957–67 annual average of 5 percent, slightly lower estimates of future growth in debt are obtained. Annual increases would average $8.5 billion in 1975–79 (Table 3, Model II).

These models project farm debt outstanding in 1980 at $140 and $136 billion, respectively. They indicate a slowing in the rate of increase of outstanding debt from recent annual rates of 10 percent to around 8 percent a decade later (Table 4).

Observe that many steps beyond the capital projection were required to obtain the projection of credit demands desired by policymakers. Suppose that additional work enabled monetary authorities to project annual deposit growth averaging 5 percent at rural banks. Given the above credit demand projections, the authorities would be concerned about the ability of rural banks to maintain their relative share of the farm credit market.

But the prevalence of assumptions in the above projections indicates their insecure foundation. More analytical work is sorely needed, and it should include the often neglected considerations discussed herein. Hopefully, it will be possible to build structural models in which these interdependent financial variables are jointly determined.

A Method for Analyzing the Effect of Taxes and Financing on Investment Decisions

GORDON E. RODEWALD, JR.

ONE of the critical problems faced by those who contemplate investments is the effect of taxes and finance charges on investment decisions. While it is known that these costs reduce the expected annual return available for retiring the investment cost, there is at present no readily applicable method of taking this known reduction into consideration in the decision process. This paper develops a method by which taxes, investment credit, and financing charges can readily be included in the decision model. A more meaningful economic appraisal of investments results. At the outset the requirement is made [1] that:

$$(1) \qquad I \leq V_0 = \sum_{t=1}^{k} \frac{E_0(Yt)}{(1+r)^t} + \frac{E_0(Mk)}{(1+r)^k},$$

where

I = the investment cost,
V_o = the value of the investment to the operator at t_o,
$E_o(Y_t)$ = the expectation at t_o on income to be generated in t,
$E_o(M_k)$ = the expectation at t_o on the value the market will generate for the asset in year k,
r = the rate used to discount expected income and market value,
t = unit of time, and
k = the number of years the asset is expected to be used.

Equation (1) can be thought of as an investment decision model in which future income and the future market value are compared with the investment cost.

Missing from equation (1) are the elements necessary to quantify the effect of borrowed money and the effect of taxes on the value of the investments. These factors can be incorporated into equation (1) without unduly complicating the arithmetic involved.

Finance charges can be incorporated by adding:

$$\sum_{t=1}^{j} \frac{C_t}{(1+r)^t},$$

where

C_t = the yearly financing charge;
j = the number of years the payments are to run.

GORDON E. RODEWALD, JR. *is an agricultural economist in the Economic Research Service. USDA.*

The modification necessary to include income taxes in equation (1) is:

$$\sum_{t=1}^{k} \frac{E_0(Y_t)(1 - Tr)}{(1 + r)^t},$$

where $Tr =$ the tax rate used to compute the income tax liability.

To reflect the investment credit provision, equation (1) is modified as with:

$$\sum_{t=1}^{i} \frac{Ic}{(1 + r)^t},$$

where

$I_c =$ the investment credit,

$i =$ the number of years the credit is carried.

In the decision model, if $k \geq 8$ the investment credit is allowed in its entirety. For $k < 8$ only a portion of the credit is allowed: if $k \geq 4 < 6$, the credit is 33 1/3 percent; and if $k \geq 6 < 8$, the credit is 66 2/3 percent [2].

The potential effect of capital gains must also be considered. A capital gain occurs when the sale value exceeds the investment cost adjusted for depreciation. For the individual the tax on capital gains can be paid one of two ways: (1) he can exclude one-half of the gain and pay tax at the ordinary rate on the remainder, or (2) he can pay tax at the rate of 25 percent on the entire amount. The effect of the capital gains can be handled by modifying the last term of equation (1).

$$\frac{\left[I - \sum_{t=1}^{k} D_t - E_0(M_k)\right](1 - Tc)}{(1 + r)^k}$$

where

$D_t =$ the annual amount of depreciation

$T_c =$ the tax rate on capital gains.

The modified decision model now appears as:

$$V_0 = \sum_{t=1}^{k} \frac{E_0(Y_t)(1 - Tr)}{(1 + r)^t} - \sum_{j=1}^{j} \frac{C_t}{(1 + r)^t} + \sum_{t=1}^{i} \frac{Ic}{(1 + r)^t} + \frac{\left[I - \sum_{t=1}^{k} D_t - E_0(M_k)\right](1 - Tc)}{(1 + r)^k}. \tag{2}$$

Using equation (2) as a basic equation, the required annual increment can be determined with:

$$E_0(Y) = \left\{ \left[I + \sum_{t=1}^{j} \frac{C_t}{(1+r)^t} - \sum_{t=1}^{i} \frac{Ic}{(1+r)^t} + \frac{\left[I - \sum_{t=1}^{k} D_t - E_0(M_k) \right](1 - Tc)}{(1+r)^k} \right] \frac{r}{1-(1+r)^{-k}} \right\} \frac{1}{(1-Tr)}, \tag{3}$$

where $E_o(Y)$ is the minimum annual return required to retire the investment cost in k years after adjustment for taxes.

The expected value remaining to be recovered if the asset is disposed of after k years of use is determined by:

$$I - \sum_{t=1}^{i} D_t - E_0(M_k) = \left\{ \left[I - \sum_{t=1}^{k} \frac{E_0(Y_t)(1-Tr)}{(1+r)^t} - \sum_{t=1}^{i} \frac{Ic}{(1+r)^t} + \sum_{t=1}^{i} \frac{C_t}{(1+r)^t} \right] (1+r)^k \right\} \frac{1}{(1-Tc)}, \tag{4}$$

where

$$I - \sum_{t=1}^{k} D_t - E_0(M_k)$$

is the tax adjusted expected value remaining to be recovered at any year k.

The effect of the taxes and financing charge, using a cattle feeding system to illustrate the decision model implied in equation (1), is shown in Table 1. The investment cost was \$112,264 of which \$75,000 was financed to be repaid in 5 years with interest at 7 percent of the remaining balance. Investment credit was carried forward according to the yearly tax liability. Equation (3) is used to calculate the required annual increment shown in Tables 1 and 2. The consideration of all costs in the investment decision reduces the economic feasibility of an investment by (1) extending the period required to recover the investment cost and (2) decreasing the allowable rate that can be used for discounting. The magnitude of these expected effects is great enough to demonstrate that, if adequate investment evaluation is to be made, the investor needs to make good estimates

Table 1. Annual required increment for an investment of \$112,264 when taxes and financing charges are included as costs

r \ k	Annual required increment			
	6	7	8	19

15	35,391	32,191	29,160	21,807
	Annual required increment with no taxes or financing			
6	22,830	20,111	18,079	10,118

of the added costs that result when investments are to be made in income generating assets.

In Table 2 the required annual return is shown when only taxes are considered. The effect of both taxes and financing can be seen by comparing Tables 1 and 2. When *k* is less than 8, the investment credit offsets a part of the tax liability, lessening the effect of taxes on the required return. The effect of the credit diminishes as *k* increases.

The decison model presented in this paper provides insights into the importance of taxes and finance charges in investment evaluations. The analysis demonstrates that not including taxes and finance charges would overestimate the repayment capabilities of the investment for any specified expected use period. Overestimating the repayment ability could lead to a loss to the decision maker if the expected value remaining to be recovered is subject to test in the market before the end of the expected use period. The method is flexible in that any part of the costs that do not pertain can be dropped without altering the remainder of the equations.

ECONOMICS OF ENVIRONMENTAL CONTROL

CHAIRMAN: MAX M. THARP, ECONOMIC RESEARCH SERVICE, USDA

Economic Issues in Controlling Agricultural Pollution*

GARY C. TAYLOR

OUR present problems of environmental pollution result from more intensive use of our natural resources and from slow rates of collective adjustment to rapid technological changes. They also result from rapidly rising standards of environmental quality demanded by a better educated, better informed, more affluent, and more mobile population. Environmental pollution may be defined as those interactions of men with their physical surroundings that result in diminished levels of well-being. This definition emphasizes the importance of changes in perception of the observers as well as changes in the characteristics of the physical environment. Thus, pollution problems result from changes in the presence or perception of the "victims" as well as from changes in the activities of the "pollutors."

Discussion, controversy and confusion concerning pollution of our physical environment has risen sharply in the past few years. Increasing anxiety about pollution among the general public is leading to actions through all levels of government. The agricultural industry and rural people are directly involved in their roles as both pollutors and victims of pollution. However, the major issues involved are much broader than agriculture alone, and the problems of agricultural pollution can seldom be considered in isolation from the general problems of environmental quality.

The objectives of this paper are: (1) to stress the multiple decision-making aspects of controlling environmental pollution; (2) to highlight a number of significant economic issues involved; and (3) to suggest some significant areas where economic research can contribute to reduction of agriculturally related pollution.

Agriculturally Related Pollution—The Problem Areas

The agriculturally related pollutants now considered problems are pesticides, animal wastes, sediment, plant nutrients, inorganic salts and min-

GARY C. TAYLOR *is chief of the Environmental Economics Branch of the Natural Resource Economics Division of the Economic Research Service, USDA.*

erals, forest and crop residues, agricultural processing wastes, and smoke, dusts and other air pollutants [9]. The discussion of pesticide residues is particularly audible at the moment. The persistent chlorinated hydrocarbons are of major concern. Several states have imposed or are considering spray bans or other stringent controls on the use of persistent pesticides.

Animal waste production is approximately two billion tons per year. Roughly half of this waste is associated with concentrated livestock production. This problem is expected to become more serious as economies of livestock production are exploited through fewer and larger operations and as cheaper chemical fertilizers more completely replace the use of animal manures.

Sediment is our largest single pollutant of surface waters. Approximately a billion tons reaches major streams annually. Sediment is important as a carrier of plant nutrients, pesticide residues and infectious agents.

Plant nutrients from soils, animal wastes, and fertilizers have contributed to locally serious problems of excess aquatic growth (eutrophication) and nitrate contamination of ground water supplies. Saline irrigation drainage waters are an important problem in arid areas.

The high organic content of forest and crop residues and agricultural processing wastes is a major problem in many areas. Low utilization values present solid waste disposal problems. Burning may create air pollution. Serious water pollution can result from placement or wash into surface waters.

Decision Making for Environmental Management

Decisions on environmental management are made by millions of individuals and organizations. Optimum patterns of environmental management require that these decisions be directly or indirectly coordinated. The difficulties of achieving coordination are enormous. Objectives are multiple and conflicting. Information is limited. Decisions are sequential and constrained. Furthermore, our political economy and social value systems have so evolved as to make it relatively easy to mobilize sufficient power to effect rapid technological changes. But at the same time it is more difficult to launch efforts of similar force and speed to attack pressing social problems that may result from ongoing technical changes.

I propose to highlight a number of economic issues within a three-tier hierarchy of decision-making levels [4]. These levels are: first, the individual or firm; second, the bureaucratic and legal systems that operate to facilitate and constrain decisions at the first level; and topmost, the arenas of the legislatures, the commissions, the high courts, and even the industry board rooms where broad decisions affecting the second level framework are made.

Decision Making in the Legislative Arenas

Much of the present turmoil over environmental quality results from inadequate representation of the perceptive pollution "victims" in the political decision-making process. These "third parties" are currently being represented to a large extent in the national communications media. What is a socially desirable and economically efficient means for their representation within the political process? Citizen advisory groups? Scientific advisory boards? Court actions?

What level of government should assume responsibility for control of specific environmental problems? Involved are the specific instruments appropriate for program action—taxation, subsidy, education, regulatory powers; the representation of concerned parties; and the capability to build effective bureaucracies with adequate technical competence and research support. To oversimplify, the preponderance of discretionary spending power rests at the Federal level, the broadest regulatory powers reside with the states, and it is widely believed that the views of the citizens are best represented through their local governments. Allee and Clavel, in their study of poultry waste pollution, concluded that effective compulsory regulation would probably require the technical capability and legal powers residing at state or regional levels [1].

It is analytically frustrating when legislatures do not specify clear and definitive objectives for public programs. Part of this situation results from sequential decision making on problems at hand combined with a general lack of capability to simultaneously review previous decisions for inconsistencies. However, part of the specification problem results from uncertainty about the probable effects of alternative decisions. The responsibility for vagueness lies partly with those individuals and institutions who should anticipate information needs and make it their business to reduce the areas of uncertainty at the time of decision. In the complex area of environmental quality, the probability is particularly great that legislative objectives will be either vague or overly narrow.

Decision Making in Bureaucratic and Legal Systems

The issues at the second level are concerned with the structure and performance of systems of constraints and incentives influencing decisions and actions by individuals, firms and groups [3]. We know relatively little about the influence of our legal framework, e.g., courts, tax systems and financial regulations, within the web of constraints and incentives surrounding our individual environmental managers. In action programs, what are the effects on management decisions of subsidy, regulation, education, or technical assistance activities?

At the program levels, there is the same universal need to make decisions based on incomplete information about feasible alternatives. How much time and resources can be allocated to reduce areas of uncertainty? Under recent Federal legislation, air and water quality standards are established on a Federal-state basis. How can these standards be met? Which instruments or combinations of regulation, financial incentives, education and technical assistance are effective, efficient and desirable for different environmental problems and situations?

If regulations and police power are to be employed, the regulations must be reasonable, equitable, effective, enforceable, widely understood, and reasonably "popular." What will various systems of regulation cost? Given the relatively high tolerance of Americans for illegal activity, what are reasonable assumptions as to levels of compliance under compulsory regulations?

McNabb has observed, regarding feedlot pollution control, that the effectiveness of extension education programs in achieving satisfactory vouuntary regulations is in doubt but that compulsory regulation, if eventually needed, will be achieved more easily and will no doubt be more effective if based on widespread understanding achieved through earlier efforts toward voluntary regulations [5, p. 36].

The economic issues surrounding the use of financial incentives for pollution control; subsidies, loans, general and specific taxes or fines are familiar to us. Who benefits? Who pays? What is efficient and what is equitable? If A pollutes B's environment, does A owe B or should B pay A to control pollution? What is an effective and/or efficient cost sharing arrangement?

There are also the issues of income distribution. Carlson has pointed out that the current establishment of air and water quality standards is a struggle between groups who will bear the burden, e.g., municipalities and industry, and the beneficiary groups, often of higher socioeconomic status, such as outdoor recreation enthusiasts [3, p. 85]. He feels, in the case of water pollution, there is evidence that redistribution of income will be regressive, benefiting higher income groups. However, in our political decision-making process, we may anticipate some adjustments between the setting of standards and their achievement.

Pollution controls may result in redistribution of incomes from upstream to downstream water users and from established resource users to subsequent resource users. Stepp has discussed the interregional income distribution issue regarding the nondegradation requirement that Federal-state waters be maintained at least at present quality levels. Had the founding fathers enforced a nondegradation erosion standard, as part of our land policy, agriculture might be limited to the thirteen original states [8, p. 6]. The point, of course, is the necessity to consider the distributional effects of environmental controls in a broad context.

The establishment of environmental controls requires compromises between the need to maintain a reasonably stable system of constraints and incentives for efficient programming of production and consumption and the need to provide sufficient flexibility to adapt the incentive system to changing technology, changing sets of tastes and preferences, or new pollutants.

The question of bureaucratic flexibility has both organizational and technical information aspects. Are generally coordinated groups of environmental agencies with narrow objectives more effective and flexible over time than superagencies with broad objectives? Federal-state programs may be more or less flexible than separate programs. How effective are advisory groups or expert consultants in achieving bureaucratic flexibility?

Decision Making by Individuals and Firms

In considering decisions by individuals and firms, it appears we have returned to more familiar ground. Perhaps, but there are still the continuing unresolved issues of benefit-cost analysis. There are the continuing ignorances surrounding the incentive effects of various taxation systems and the continuing lack of research effort on them. One of the most important questions is how governmental actions can be designed to strengthen incentives for private or voluntary decisions to manage the environment in socially desirable ways. Voluntary action in our society is considered the key to solving social problems. Even the use of police power must be predicated on voluntary compliance by the vast majority. What are the feasible and effective alternatives for achieving a widespread sensitivity about relationships between individual actions and environmental problems? What legal or program changes would reward ingenuity, development of new technology, or changed patterns of operation to reduce environmental problems?

There is the question of how individuals in various situations and various roles perceive environmental pollution situations. What do they want changed? How should it be changed? Who should change it? Who should pay for it? Because of the technical complexity of many environmental problems, large groups may be unaware, misinformed or apathetic. If so, how can this situation be reflected in decision making on environmental control?

A Strategy for Socioeconomic Research

Having considered some of the issues, what research should we undertake? It would be fine to be able to conclude that we should research the economic aspects of all these issues plus those new questions uncovered in the process. Realistically, we must content ourselves with some selected efforts.

Although there are some serious deficiencies in our theoretical concepts, the pressing need for improving the pollution control decisions involves empirical economic information. The lead priorities should be given to the empirical problems, most of which are within range of our present conceptual grasp.

Empirical case studies of pollution situations are needed. There is little information on costs and benefits for specific situations. We need to determine who is really burdened by pollution by tracing through the effects in real situations. Information is needed on the timing of pollution damages. The costs of alternative means of control are often very sensitive to the probabilities of critical pollution occurrences. It is only through development of valid information from empirical studies that the widely conflicting claims of benefits and costs can be narrowed and significant progress made toward the development of efficient means of environmental control.

The complexity and interrelated aspects of environment management support a systems approach to many of the problems involved. Both the economic effects and environmental effects should be considered. The economist and ecologist share a common systems concept in the initial stages of problem solving at least. The potential for mutually beneficial collaboration on environmental problems should be more fully explored.

Ayres and Kneese, in considering solid wastes as a materials handling problem, have demonstrated the usefulness of the systems approach for considering possible alternative actions and for highlighting critical needs for additional research [2]. For example, there has been some agitation for banning chemical fertilizers because of high nitrate incidence in food and drinking water supplies. Smith has pointed out, however, that a third of our present crop production is dependent on chemical fertilizers [7, p. 174]. A general study of nitrates using the systems approach could be useful in delineating the possible effects and costs of various fertilizer use controls.

Relatively little information is available on the reaction patterns to environmental control programs that might be anticipated from firms and groups in various representative situations. Pollution regulation may have a significant effect on the location of individual agricultural firms and the competitive positions of various producing and processing areas. Water pollution regulations, for example, might be expected to give those areas with heavy rainfall and fast moving streams a competitive advantage for firms generating large volumes of oxygen-demanding waste water.

More information is needed on the costs to the agricultural firm of alternative means of pollution control. In addition, we need to look ahead and design efficient systems of food and fiber production that will minimize pollution as a way of doing business.

While the present sources of agricultural data are not completely adequate to support environmental control decisions, there is still considerable potential for useful exploitation. Additional sources of data on the extent, location and severity of agricultural pollution will need to be developed. Some efforts have been made toward developing indicators of social welfare [10]. These efforts should be continued and expanded to more accurately gauge trends in environmental conditions.

For many important questions, it is obvious that the economic researcher will be dependent on inputs from other disciplines. Studies of environmental perception, for example, will require collaboration with other social scientists. The agricultural economist, by training and experience, is often able to work effectively in this type of situation. The particular vehicle for including other disciplines in the research approach—literature review, consultation, coordinated projects or operations research groups—depends on the nature of the problem, the resources available, and the personalities involved. However, the complexity of the problems of environmental control makes it extremely difficult to keep adequately informed on research developments in the several related disciplines.

The complexity and dynamic aspects of environmental quality problems insures that we will not lack for challenging research questions. In fact, the variety of questions provides abundant opportunity to satisfy both our intellectual curiosity and our professional obligation for relevance to pressing social issues.

Environmental Effects of Rural Land Use

J. DELPHENDAHL

ECONOMIC growth in the United States generates various phenomena, one of which is its urbanizing effect on the entire society. This urbanization process likewise affects rural communities and the use of land resources in rural areas. National attention has been focused recently on social and economic conditions in rural America [11]. Economic growth brought also a much greater interdependence of people, regions and resources. The economic hinterland of a "fundamental community of 1968 is about 50 miles and its area is about 5,000 square miles . . . the functional economic areas of 1968 include from 100,000 to 200,000 or more people" [5, p. 1139].

The term rural land use, might be subject to different interpretations because the differentiation between urban and rural land use has recently become blurred, especially when analyzed from a sociological and economic point of view [1]. The use of land resources is frequently associated with the resource oriented industries such as agriculture, forestry, mining, and, in coastal areas, the fishing industry. Rural land use is sometimes used as a synonym for sparsely populated areas of the United States. I wish to define rural land use as the physical and economic supply of natural resources in non-urban areas, where urban is to include the urban fringe area. Rural land use, or somewhat rephrased, the use of the open country, currently receives national attention as a "by-product" of the emphasis placed on the quality of environment.

Several trends are affecting the current use of land resources in rural areas. Clawson observed in this respect that "a major but unplanned and unguided redistribution pattern of the population on land is underway in the United States" [4, p. 65]. Rising disposable income generated an increase in demand for a large number of outdoor recreation opportunities, as well as for seasonal (or second) homes. The location of these homes has an impact on the land use pattern in rural areas. The interstate highway system provides easy access to rural areas and connects these areas with metropolitan regions. It, too, is a major factor affecting the use of land resources in these areas.

I wish to divide my paper into three major parts. First, trends in rural land use will be briefly discussed, followed by a discussion of externalities and their effects on the use of the open countryside. Finally, some alter-

---

Table 1. Major uses of land, United States, 1964

Land use	Acreage	Percentage of total
	million acres	percent
Cropland, including land in rotation	444	19.6
Grassland pasture and range[a]	640	28.3
Forest land[b]	732	32.3
Special uses[c]	173	7.6
Miscellaneous other land[d]	277	12.2
Total land area[e]	2,266	100.0

Source: [6, p. 2]

[a] Excludes cropland used only for pasture.

[b] Excludes 30 million acres in special uses.

[c] Urban and transportation areas, areas used for recreation and wildlife purposes, public installations and facilities, farmsteads, and farm roads.

[d] Marshes, open swamps, bare rock areas, desert, tundra, and other land generally having low value for agricultural purposes.

[e] Includes streams and canals less than $\frac{1}{8}$ mile wide; and ponds, lakes, and reservoirs less than 40 acres in area.

natives will be advanced related to the minimization of the effects of externalities.

Trends in Land Use

A superficial examination of land use changes in the United States between 1959 and 1964 might easily lead to misinterpretation. The aggregate data do not reflect regional differences in local shifts in the use of the wide open countryside [4, p. 90]. Major uses of land in the United States are given in Table 1. Twenty percent were classified as cropland but only about 15 percent were actually utilized for this purpose. Land resources in the "special use" categories account for about 8 percent [6].

A comparison of these two land use classes is made because national and state parks, wildlife refuges, and wilderness are included in this classification. It is hypothesized that parks, refuges, and wilderness areas are generally located in the open countryside. The trend of cropland use during the last several decades is well known, and therefore the discussion of land use changes is confined to the special use category. The distribution of this use category, however, varies among regions, as can be seen from Table 2.

In the Northeastern and Pacific regions, 17 percent of the total land area is used for special purposes. The percentage declines in the Lake States, Corn Belt, and Mountain areas to 12 percent. The Appalachian region follows with 9 percent. Only 6 and 5 percent of the land area of the Northern Plains and Southern Plains, respectively, are classified as "other type" of land use. The distribution of cropland, pasture, and range land, and

Table 2. Regional percentage distribution of cropland, pasture, and range, and special use categories

Regions	Cropland, pasture, and rangeland	Combined special uses[a]
Northeast	23	17
Lake States	44	12
Corn Belt	69	12
Northern Plains	92	6
Appalachian	32	9
Southeast	25	11
Delta States	32	9
Southern Plains	79	5
Mountain	65	12
Pacific	39	17
Average 48 states, excluding Hawaii and Alaska	57	11

Source: [6, p. 8].

[a] Includes cities and towns of 1,000 or more population, highway and railroad rights-of-way, airports, national and state parks, wildlife refuges, wilderness areas, national defense lands, Federal flood-control areas, farmsteads, feedlots, ditches, farm roads and lanes, swamps, bare rock, deserts, and tundra.

the combined special use category for the northeast region shows only 6 percentage points difference between these categories.

Shifts in Land Use 1959-64[1]

Between 1959 and 1964, an annual average of 3.4 million acres were shifted to special uses. The shift of land resources to rural transportation uses should be mentioned not only from the aspect of "consuming" natural resources but also as a type of externality affecting the land use pattern in rural areas. About 160,000 acres annually were shifted during the period 1959 to 1964 to rural transportation. The construction of the national network of interstate and defense highways accounts for a large portion of the shift in land resources. Estimates made suggest that about one million acres per year are shifted to special uses. An additional one million acres annually are converted to what Frey et al. called "extensive-type public acreage (recreation and wildlife and public installation and facilities)" [6, p. 29].

Effects of Externalities

In broad terms, land use in the United States is subject to two major constraints: the institutional framework and the market mechanism. The broad institutional framework always plays an important role in land resource use and management. The operation of the market mechanism that facilitates the movement of resources to the highest bidder does function to some degree within the institutional constraints of numerous public policies. These two major constraints permit both public and private activities in the management of natural resources, though Castle observed that "government intervention undoubtedly has been greater for land than for other factors when one views the entire economy" [3, p. 545].

---

[1] This section draws heavily from Frey et al. [6, pp. 27–29].

One may hypothesize, however, that public policies related to the management of natural resources may become more restrictive if the recent spur in public concern about the quality of environment serves as an indication of future developments. This comment should not be construed as a value judgment about the merits of public management of natural resources.

It is the basic premise of this paper that externalities have an impact on the use of land resources in rural areas. I would like to treat the numerous public policies related to the factor and commodity market as externalities because the decision making unit is geographically removed from the area affected by the particular policy. Examples of such externalities include the vast array of policies ranging from land retirement programs to soil conservation programs, and especially the large number of area development programs. The following will illustrate this point. Many resource-based outdoor recreation areas, especially those located in the northern tier of the country, experience an influx of a large number of users during the relatively short summer outdoor recreation season. Since frequently no entrance limitation exists, except a nominal user fee, many of these areas are over-used. The majority of the users are out-of-state residents.

A 1966 study of second (seasonal) home ownership in northern New England showed that 46 percent of the owners resided in "surrounding and nearby states" [14, p. 5]. Many seasonal homes are located in rural areas where little or no land use planning exists. Many of these second homes cause "scenic pollution" because they spoil locations that have been aesthetically attractive.

I selected the term "beneficial" externality to denote policies that are generally considered to have a beneficial impact on rural land resource use. The location of a new industry in a rural area might be desirable, if it creates employment for the local labor force and therefore increases the local aggregate income. Jordan found that about "13 percent of the increase in total personal income in an eight-county Ozark area in 1960–63 can be attributed to employment" in an industry which began operation in 1960 [8, p. 4]. The results of the study of the economic impact of a state park indicate that campers spend $3.10 per person per day in the economic area of the park. It was estimated that the local income effect, using a multiplier of 1.55, generated by the state park from 1962 to 1967 amounted to

$718,798. The largest percentage of users of this outdoor recreation area are non-residents [2].

Another type of externality is characteristic of rural areas adjacent to an urban center in a radius of approximately 50 miles. They are becoming part of the living space of "rural" urban-residents who commute to their urban jobs. These are people who prefer the low density living of the rural area [12, p. 5]. Again, decisions made by the decision-making unit located outside the area under consideration will have a profound effect on land use.

Turning now to some examples of "detrimental" externalities, one can cite numerous examples of poorly designed subdivisions, uncontrolled development along country roads, or uncontrolled "cottage" development at the shores of many lakes. The pattern of regional economic growth is another type of development that affects rural land and should probably be treated as an externality. External cost savings will lead to agglomerations of industries and services that are interdependent. This process of agglomeration is one reason for the continuous growth of the metropolitan areas as well as stability or relative decline of many rural areas [10, pp. 25–26].

Alternatives to Minimize the Effects of Externalities

Externalities do exist and they exert considerable influence on the use of land resources. I would like to pose a question related to alternatives for minimizing externalities: What type of land resource use and settlement pattern do we as individuals, and as a society, prefer in the future; or, rephrased, what kind of environmental quality do we want?

Allen Kneese, in his recent monograph, suggested that "economists interested in public policy problems associated with resource development and use have usually worked within the conceptual framework of welfare economics" [9, p. 165]. As observed above, land resource use is partially determined by institutional arrangements and by the market mechanism. Thus, anticipated policy alternatives to change the effects of externalities must be politically feasible. Such an alternative was suggested by a Congressional Committee: ". . . society begins to accept common sense trade-offs" [13, p. 12]. Closely related to the concept of trade-offs is the question whether society is willing to pay for such trade-offs.

Several states enacted preferential property tax laws for the purpose of influencing land resource use in rural areas and in urban fringe areas [7]. This measure to influence land resource use is still relatively new, and its effectiveness therefore has not yet been fully appraised.

Rural zoning is another alternative frequently mentioned. Theoretically rural zoning is a possibility, but at this point in time it can be considered a novelty of land resource planning for most rural areas of the United States. Rural zoning has not yet gained broad political support and public acceptance.

Summary

To summarize, it has been shown that externalities influence the use of rural land resources. Examples of beneficial and detrimental impact of externalities have been cited. Alternatives suggested to minimize the effects of externalities include trade-offs, tax incentives, and rural land use planning.

Externalities in Pesticide Use*

Max R. Langham and W. F. Edwards

THERE is in this country a growing desire for participatory decision making. People want their views considered in policies which may affect them, and they are encouraged by the successes of modern technology to demand policy solutions requiring little personal sacrifice. Evidence of this attitude exists in the current pesticide controversy. Many people who are opposed to the use of chlorinated hydrocarbons do not take the agriculturalist seriously when he states that the banning of these "hard" pesticides would reduce the quantity and quality of food available. These opponents do not see the problem as a choice of an adequate quantity and quality of food *or* a clean environment, but rather as one of determining how to have a clean environment without sacrifices in food production. Anyway, there is this growing pressure for our socioeconomic system to become more sensitive to all potentially relevant externalities and to include them in decision processes. Our work with pesticides was partially motivated by this pressure.[1] Specifically, we have attempted to incorporate externalities from the agricultural use of pesticides in Dade County, Florida, into a decision model to help provide a basis for more socially acceptable decisions regarding pesticide usage.

Externalities

Buchanan and Stubblebine [2, p. 372] state that an externality exists when the actions of one party (B) affect the utility (production) function of another party (A) who has no control over B's action. Their definition is exhaustive, since the end result of all economic activity is to affect and influence individual utility and/or firm production functions. They indicate that an externality is potentially relevant when it generates a desire in A to try to influence the action of B. Such will be the case whenever A's utility is not at its global optimum with respect to B's action.

Buchanan and Stubblebine's definition is myopic from the point of view of policy, since it assumes a given set of property rights and a given in-

Max R. Langham *is associate professor of agricultural economics and* W. F. Edwards *is research associate at the University of Florida.*

come distribution. In policy formulation, however, rights and income distribution are potentially variable. Herein lies a measurement dilemma for the researcher. If the policy making process is to make acceptable and somewhat durable decisions, it must consider the total costs and benefits of alternative courses of action for each participant in the system without regard to established rights. But if measurement is to have an empirical basis, it must of necessity be founded in a given set of rights. Since we found no solution to this dilemma, our measurements of cost and benefits are based on the set of rights that existed at the time our data were generated. However, from this point on, we submerged the problem of property rights and were concerned with measuring the net benefits of alternative pesticide usage policies without regard to rights. Therefore, the concept of a potentially relevant externality, as defined by Buchanan and Stubblebine, constituted the framework within which we attempted to define a measure of social welfare.

Externalities cannot be meaningfully studied independently of the system which generated them. In looking at policy alternatives with regard to pesticide use, one must attempt to measure the total impact of a policy on the system. This task requires that one look at the participants (individuals or groups of individuals) in the system to see how each is affected by a particular policy. For example, we defined three participants—consumers, producers, and others. Each of these is a role oriented aggregate of individuals (that is, a given individual might play any combination of the three roles). The aggregate termed "others" included those people who were affected by the system while not engaged in a role as consumer and/or producer. The measures we chose to determine the effect of various policies on the participants were consumers' surplus, producers' surplus, and a dollar measure of external effects on the group termed "others."

One's definition of welfare for each participant of a system provides the criterion for identifying which potentially relevant externalities require explicit treatment. For instance, our measure of producers' surplus included some potentially relevant externalities as defined by Buchanan and Stubblebine. Therefore, our concern was with identifying and measuring those externalities that were *not* included in the surplus calculation.

We undertook the identification of externalities for empirical measurement in a systematic way but found it to be a rather ad hoc process. Each externality tended to be unique and could not always be objectively identified. For example, since insurance premiums are a cost of production, one could reason that the costs of an accidental poisoning of an agricultural laborer would be included in the computation of producers' surplus. However, insurance companies have no actuarial basis in their policies for accidental poisoning. As a result one could argue that the social cost of accidental poisoning is not reflected in the cost of production and to date has been so minor that it has not been of explicit concern to insurance companies in determining their rate structure.

Measuring Externalities

Considerable effort is required to get even crude measurements of externalities. First, there is little basis in economic theory for nonmarket measurement.[2] Second, because of past research inactivity in the area of non-market measurement, there has been little pressure for the collection and reporting of some very basic kinds of data. In the case of pesticide pollution, however, data availability is improving somewhat. Pesticide residue monitoring work on air, soil, water, food and feed, people, fish, wildlife, and estuarine sediments has been started.[3] But little is being done in a systematic way to measure the inputs of pesticides into the environment.[4] This lack of information on inputs will delay the determination of relationships between inputs and subsequent levels of residues as determined by the monitoring efforts. Furthermore, little is known about the relationships between damage to an environmental element and its level of pesticide residue.

In our pesticide work an attempt was made to by-pass the physical cause and effect relationships that exist between pesticides and externalities. Effort was aimed at relating a dollar measure of the social costs of externalities to the amount of a pesticide used. This effort had some rather severe limitations, however. First, only those externalities that could be observed were measured. By and large, these were acute external diseconomies which created controversy. Second, in many cases the measurement of an externality was uncomfortably subjective in that it lacked a market determination. Finally, the use of a dollar measure for social cost also required some strong assumptions concerning the marginal utility of money and income effects of price changes.

Our objective in measuring externalities was to obtain structural estimates of the function:

$$(1) \qquad C(t) = h[z_1(t), z_2(t)]$$

---

[2] A recent paper by Ayers and Kneese [1] relates environmental externalities to some conventional models of production and consumption.

[3] A description of these programs is contained in [4].

[4] Two nationwide surveys to obtain regional (multistate) estimates of the agricultural use of pesticides have been coordinated by the Farm Production Economics Division of the Economic Research Service. A third is being considered and future plans call for obtaining similar estimates as part of the soil monitoring work. The effort helps fill a complete void, but it does not provide data at the local and state levels and it is limited to agriculture.

where $C(t)$ is a net dollar measure of externalities in period (t) and $z_1(t)$ and $z_2(t)$ are organic phosphates and chlorinated hydrocarbons, respectively, both in pounds of 100 percent active agent used on farms in Dade County in period (t).

The pesticide controversy mainly revolves around the two groups of pesticides defined as z_1 and z_2. The organic phosphates are highly toxic but non-persistent in the environment. Most accidental deaths and illnesses are caused by pesticides from this group. By contrast, the chlorinated hydrocarbons are relatively non-toxic and cause very few problems in the short run. But they are persistent (the half-life of DDT is over 10 years), and the possibility of their detrimental effects on the environment has created considerable social anxiety.

We found the specification and empirical estimation of equation (1) to be an interesting but frustrating experience. The conservationists view this equation as increasing at an increasing rate in z_2. Others, including most farmers, believe that the majority of costs are associated with accidents and suicides, which increase at a decreasing rate as more z_1 and z_2 are used.

After considerable effort, we were able to obtain an estimate of one point on this function for the 1966–67 crop year. We plan to use sensitivity analysis to test the stability of the model solution as the form of the function through the point is varied. Work to date indicates that pesticide usage policies are somewhat insensitive to the level of the point when one assumes a linear function through the origin.

To obtain an observation on the arguments in equation (1), we used the records of farmers and suppliers of pesticides. An average per acre usage by crops and by type of pesticide was developed and then expanded to obtain the county estimates. Sources of information on externalities included growers, insurance claims, veterinarians, biologists at the Everglades National Park, the National Audubon Society, and the Community Studies on Pesticides Program of the United States Public Health Service.

The diagnosis of pesticide poisoning of humans and pets was not precise. If pesticide poisoning was diagnosed, it was usually attributed to an organic phosphate—most often parathion. Our total cost estimate of $4,600 for the 1966–67 crop year in Dade County included those cases about which there was doubt and in this sense was biased upward for the organic phosphates.

There was very little substantive information on chronic effects of the chlorinated hydrocarbons. We have done some conjecturing (again through sensitivity analysis) about the consequences of different levels of chronic effects upon pesticide usage policies.

Incorporating Externalities into Policy Decision Models

Since Marshall first developed the concepts, economists have vacillated about the use of consumers' and producers' surplus as a measure of social welfare. Hotelling [8] and Hicks [7] revived professional interest in the surplus concept, and it now appears to have a growing acceptance as a measure of welfare for policy decisions [5, 10, 11]. Samuelson [9] remains one of its strongest critics.

The social welfare function has been useful as a theoretical construct, and revival of the surplus concept has provided one measure of welfare that is not only empirically operational but has a theoretical basis. This gain in operational significance for empirical work is probably one of the most important factors in the growing professional acceptance of the surplus concept—probably more important than the merits of the concept itself.

In their work Headley and Lewis stated society's objective "as securing that level of pesticide usage, given the technology at any point in time, that provides the maximum positive benefits over and above the negative benefits or costs associated with that level of usage" [6, p. 24]. To help attain this objective they suggested an empirical approach to the study of alternative pesticide usage policies, which was based on the concept of consumers' and producers' surplus with modification for "spillover effects" that were relevant from society's point of view but were not included in the surplus calculation.

Our approach to incorporating externalities into a decision framework for pesticide usage policies was essentially a generalization of the method suggested by Headley and Lewis. For selected pesticide usage policies, our model maximized a measure of consumers' and producers 'surplus over production alternatives available to the region. In each case the objective function explicitly recognized measurable externalities not accounted for in the consumers'-producers' surplus calculation. The maximization was restrained by flexibility constraints derived from historical cropping patterns. Finally, the policies were ranked by their maxima.[5]

Model work is under way on policies to reduce the use of chlorinated hydrocarbons. In the range from 50 to 100 percent of current per acre usage of chlorinated hydrocarbons, entomologists with whom we have consulted agree that under "average" conditions 0.3 pounds of organic phosphates will replace 1.0 pound of chlorinated hydrocarbons, both 100 percent concentrated. With this rate of substitution, results indicate that the usage of chlorinated hydrocarbons can be reduced with only minor implications for consumers, producers, and others. And the growing indication of some chronic risks associated with the use of chlorinated hydrocarbons may justify such adjustments.

---

[5] The model was quadratic in the objective function and linear in the constraints. A specification of it is available from the authors.

The model has proven to be efficient in using data and is an empirically operational device for obtaining added information on the effects of externalities on the solution determined in a free market decision framework. Use also indicates that the model will be helpful in appraising policy alternatives. Our work supports the hypothesis that economists are better equipped to determine the implications of externalities than they are to measure them.

Concluding Remarks

We would like to conclude with a value judgment and a plea. The value judgment is that the responsibility for insuring that externalities are recognized in decision processes should not rest solely on externally affected parties. Society instills in each of us a great tolerance for the status quo, and if improvements in the operation of our socioeconomic system depend on individuals being "fedup," the process of improvement will be slow—perhaps dangerously so if the affected parties hold few resources and little political power. Social scientists need to be concerned with minimizing the "true" social cost of change.

Our plea is for greater support for measurement of the inputs and outputs of the environmental production function. Little is known about the quantity of potential pollutants going into our environment, and even less is known about the physical effects that are the outputs—even those that are acute and can be observed. Economists are being asked to help make decisions about environmental processes, and they know neither the quantities nor values of their inputs and outputs.

Such monitoring of inputs and outputs would not be a simple task. There would be problems of identifying the true cause of certain observed phenomena, and there would be uncertainties about "who killed Cock Robin." The social question of "so what" would also remain, and the role of value judgments would come to the fore. But if it is important that society consider the consequences to its welfare of alternative courses of action, we as economists must encourage appropriate observational processes. The existence of data will in turn encourage more economists to empirically study environmental problems.

CHAIRMAN: HARRY C. TRELOGAN, STATISTICAL REPORTING SERVICE, USDA

A Rural Economic Indicator System

CLARK EDWARDS

THE demand for indicators describing the nonfarm economic environment of rural residents is increasing faster than the supply. A rapidly changing economic environment for farmers and other rural people is leading to accelerated economic and social adjustments for residents of farm, rural nonfarm, and urban places. Continued maldistributions of income among families, places of residence, and geographic areas are leading to increased dissatisfaction with the current economic situation. A comprehensive data base for thoroughly describing and explaining the economic environment of rural residents is nonexistent. Obstacles to setting up such a base are formidable. Collecting primary data for different project areas at different times not only limits the comparability of results among project areas but also limits the geographic range of applicability. Secondary sources of data can offer uniform coverage with respect to time and place. But the concepts reported often fail to correspond with user requirements, the reports quickly get out of date, and estimates are occasionally grossly inaccurate.

This paper deals with some activities in ERS to carry on research on rural area economic development in the widening breach of data. Given the constraint of an exceedingly limited budget, the approach has been to squeeze as much information as possible out of secondary sources. When available data didn't meet theoretical demands for empirical information, the theory was bent a little in preference to collecting new data. The approach is leading to a helpful set of descriptive indicators of regional variations in the economic environment of rural people, as well as to analytical appraisals that help to explain these variations and suggest economic development policies. An important byproduct is an improved automatic data processing environment in ERS for analysts who know economic research methods and data sources, but don't know much about computers.

Retrieval System for Secondary Data

Appraisal of the quantity and quality of secondary data available for

---

CLARK EDWARDS *is an economist with the Economic Development Division, Economic Research Service, USDA.*

economics research is sometimes reminiscent of the story about an Ozark preacher who was invited to Sunday dinner by a farmer and his wife. As the preacher was wiping his chin on his napkin after dinner and searching for just the right compliment, he heard himself saying, "That was a mighty fine dinner, what there was of it." Realizing that something was wrong, he hastily edited his remark and said, "I mean, there was plenty of it, such as it was." The latter sentiment is generally the more appropriate one in describing available secondary data sources for regional economics research, although, on occasion, one finds oneself adopting the former. Three rules used to limit the quantity and uphold the quality of data assembled were: the data source likely would be useful; the data were available at the county building block level; and the data were uniformly available for all counties. Using these rules, we estimated that there were available some 10,000 pieces of information for each of the 3,000 counties—approximately 30 million pieces of information.

Experience in copying some of these numbers onto penciled worksheets, and running up totals and means on desk calculators, soon caused us to question the word "available" as an adjective modifying "secondary data." We sought a way to automate. The Economic Development Administration (EDA) of the Department of Commerce had asked the same question about a year earlier. With their larger budget, they were working out an answer. They invited ERS to join them when they found that our data needs and user requirements were similar.

More important than the common data needs of EDA and ERS was the common approach to data assembly and extraction. Both agencies were interested in something that would become operational as soon as possible with a small core of useful data but that could be expanded as funds became available. Both agencies were more concerned with the ease of data extraction by users than with ease of data assembly by the designers of the system.

County data currently stored and operational in the system include attributes for population, agriculture, manufacturing, wholesale and retail trade, government, employment, income, and banking. The result is a useful source of benchmark information as of 1958–64. It is scanty with respect to descriptions of activity annually since. But we are working on that.

The data may be conveniently imagined as a two-dimensional array having 3,000 rows and approaching 10,000 columns. Each row represents one county; each column one attribute. Extraction of data from the system merely requires identifying rows and columns (counties and attributes) on punched cards and running them against stored data files. This merely reproduces published tables. The power of the system comes from the ease with which data can be manipulated. For examples: One can select from the 3,000 counties only those that meet certain criteria such as income per capita below $1,000; he can rank the selected counties from lowest to highest incomes; and he can generate new attributes (such as income per capita) from stored attributes (such as income and population) about as cheaply as he can simply extract data. This bypasses not only the published source but also the 10-column worksheet and the desk calculator. Users with a little computer sophistication quickly learn to move stored data into canned programs useful in economics research such as regression analysis and plot routines; or into software of their own making, say in FORTRAN.

Descriptive uses

Descriptive uses of the data retrieval system may not sound as elegant as analytic uses, but simple indicators come first and they are important. Descriptive summaries of the large volume of data into a small handful of indicators are probably the first thing brought to mind by the title of this paper. The data on file may quickly be extracted to form a *table* showing, for example, various aspects of population, income, and employment of a multi-county planning region compared with some other region during the same year or compared with itself as of an earlier period. The raw totals for the region, in conjunction with percentage distributions and various comparative ratios, make handy do-it-yourself kits for policy makers. Investigations for *associativity* suggest hypotheses for further research but, in themselves, belong on the descriptive list of products of the system. This is done by computing cross tabulations, correlations, and regression coefficients, and by preparing scatter diagrams. *Index numbers* have proven a convenient descriptive summary of large blocks of data which are used to flag geographic regions most likely to have relatively severe problems of intense poverty, underemployment, or generally poor economic health. By way of illustration, we used principal component analysis to assign weights to 10 economic and social characteristics associated with the economic health of multi-county regions.

Analytic uses

The first step in proceeding beyond the brute-force empiricism of the descriptive statistics was a multi-county delineation of the 3,000 counties into a few hundred more-or-less functional economic areas. Three candidates for this purpose undergoing testing in ERS now are about 200 regions assembled by the Office of Business Economics of the Department of Commerce, about 300 regions assembled by ERS, and about 500 regions assembled by Rand-McNally. Observations on population, income, and employment for several hundred regions are used to test hypotheses about economic development. The economic theory proving most useful in our static models is that of Keynes and the macro-economists. Micro-economic formulations have not been as fruitful in suggesting hypotheses with respect to multi-county or multi-state economic activity. Either theory has needed extensive supplementation with respect to demography and location. Analyses over time have veered away from growth models depending on capital accumulation (for which we have little regional data) towards labor force expansion through changes in migration, natural increase of population, or willingness of the population to participate in the work force. To fill these theoretical boxes with data from our information system, we have incorporated matrix algebra, simultaneous systems of equations, input/output, linear programming, and simulation algorithms.

Summary

A rural indicator system is under construction in ERS. An input to the system is a data bank containing county population, income, employment, and other characteristics. A unique feature of the bank is that all data are converted to a standard format which, while making it harder to build data files, simplifies the procedure for data extraction and manipulation by users. The data are being summarized into descriptive indicators of regional variations in economic activity, for example, with index numbers. And the data are being combined with structural information, such as that relating to resource productivities and elasticities of demand, to build analytic models for appraisals of prospects for growth in rural areas. Results so far suggest that a good deal of useful description and analysis can be derived from secondary data sources.

Farm Panels as a Source of Farm Management Data: The Cornell Producer Panel

GEORGE J. CONNEMAN

ALTHOUGH panels have been used in consumer research for a number of years, the use of a panel of producers or farmers as a source of farm management data or for studying changes on farms over time is a more recent development. Basically, a producer or farm panel is a group of farmers questioned and revisited over a period of time to obtain various types of information.

Studies using the panel technique were initiated at the University of Minnesota [9] and Cornell University [2] in 1959. These panels were directed to analyzing changes over time in the quantity and characteristics of resources associated with changes in milk production on dairy farms and to projecting future changes. At Ohio State, panels have been used as a technique for obtaining input-output data [8].

The purpose of this paper is to describe and evaluate the Cornell Producer Panel. The sampling technique and cost of obtaining data are discussed. The usefulness of such a panel in determining rates of change in size and technology and in assessing farmer behavior is considered. The advantages of producer panels over other techniques and the future use of a panel of this type are indicated.

The Sample of Farms

One of the distinguishing features of the Cornell Producer Panel is that producing units within designated areas or segments rather than "farmers" were the sampling units. The farms included in the Cornell Producer Panel represent a statistical sample from a universe of farms in the New York milkshed area.[1] The random sample is of *farm segments* or groups of farms rather than individual farms.[2] The panel was based on a 2.5 percent

---

[1] Cornell University Agricultural Experiment Station State Project 502, *An Economic Analysis of Long-Run Changes in Milk Production in the New York Milkshed,* financed by a research grant from the New York-New Jersey Market Administrator.

[2] The probability sample of milk producers selected for study was based on the geographic, systematic sample of small area segments drawn from the producing area, after stratification by region. Each segment was drawn to contain either five or ten dairy farmers whose milk was priced by the New York-New Jersey Milk Order. Although sampling was on the basis of producers delivering to New York-New Jersey plants, dairy farmers delivering to other markets and farms not producing milk were identified within each of the segments chosen. Sampling was at a rate

---

GEORGE J. CONNEMAN *is associate professor of agricultural economics at Cornell University.*

random sample of small area segments. All dairy farms and all other nondairy farms that fell within the segment area were enumerated. Area segments made it possible for farms that were not producing milk at the outset to enter the sample at a later date. Segments also allowed the measurement of the effects of farm consolidation. All potential "producing units" in each segment were interviewed regularly.

Data Obtained

Data on milk production and farm characteristics during the period June 1960 to June 1968 were gathered from a sample 1,700 milk producers in the New York milkshed area[3] included in the producer panel. Several universities in the Northeast cooperated in the project. The farm data were gathered by a combination of personal interviews and mail surveys. The initial visit to each farmer was made in 1960. Repeat personal interviews were conducted during the summers of 1961, 1962, 1963, 1964, and 1967. A mail questionnaire in June 1965, 1966, and 1968 provided some data. (A mail questionnaire was also used between personal visits in January 1961, 1962, 1963, and 1964.)

Detailed information on farm business organization and resources and the personal characteristics of the farmer and his family was obtained during the first visit. This included detailed information on current cropping systems and livestock enterprises, buildings, machinery and equipment, and labor supply. Data on the farm operator included family composition, age, off-farm jobs of the operator and his family, and tenure. Data on changes in resources and production were obtained in subsequent personal visits. The mail questionnaire in 1965, 1966, and 1968 provided current data on cow and heifer numbers as well as any change in the method of delivering milk.

Information was obtained from this panel not only on continuous producers but also on farms that went out of production (exit) and those that began production (entry). Thus, the full spectrum of changes in milk output was included. Exit producers were interviewed as to the reasons for discontinuing farming, the present use of land and building resources, and their present occupation.

On personal interviews, the rate of non-cooperation averaged approximately 2 percent each year, but the people who refused to supply infor-

---

of 2.5 percent of the New York-New Jersey Order producers. This sampling procedure is the equivalent of dividing the entire milkshed into area segments of approximately five or ten producing units, and selecting the appropriate number of sample segments by a random sampling process that ensured geographic distribution of the segments. The mechanics of drawing the sample and of evaluation of the sample from a statistical standpoint are given in [5, pp. 7–14].

[3] The New York milkshed covers parts of six states: New York, New Jersey, Pennsylvania, Maryland, Delaware, and Vermont.

mation were not the same each year. Thus, over the entire period only 14 farmers of the original 1,700 were never interviewed. This high rate of cooperation was attributed to several factors:

1. Well-trained enumerators.
2. A relatively short well-designed interview schedule, relevant to the purposes of the study as explained to the producer. Interview time on each visit was 45 to 60 minutes and dealt with resources and change in resources and not total inputs.
3. The return to producers of preliminary findings of the study between visits.
4. The between visits contacts provided by the mail questionnaire.
5. Continuity of the supervision of the project.

The mail questionnaire averaged better than 85 percent return (with an additional 5 percent return by field follow-up). Usually 50 percent of the first mailing was returned, about 25 percent after the second mailing, and the remainder following a third mailing. The mail questionnaire consisted of a 3 × 5 card with 3 questions to be returned in an enclosed self-addressed envelope. A "gimmick" was used on several occasions to encourage the return of questionnaires. The gimmicks were generally educational yet personal in nature and included: a black and white snapshot of the producer's barn, a topographic map of the area in which the farm was located, a physical map of the area, and a rain gauge. The relatively high returns by mail are attributed to the contacts by personal interviews, as well as the interest developed by the gimmicks. The gimmicks were mailed with the questionnaire rather than being offered in return for a completed questionnaire.

Cost of Obtaining Data

The data gathered by personal interview cost approximately $10.00 per dairy farm interview. This includes all direct costs except professorial direction and planning. It includes salaries and travel expenses of field enumerators but *does not* include the salary or expenses of the project leader or secretarial and office help used in tabulating records after field work was complete, although field enumerators usually were used for this purpose. The quoted cost does not include the expense of drawing the original sample.

The data obtained by mail questionnaire cost about $0.75 to $1.25 per returned questionnaire, depending on cost of the "gimmick" included. Only a limited amount of data on cow and heifer numbers and change in method of delivering milk were obtained by the mail questionnaire.

Advantages of the Panel Technique

The Cornell Producer Panel has definite advantages over other methods of studying and analyzing certain types of changes. Since the producer panel uses the individual farm as the basic unit of inquiry, the panel provides a record of the actual changes in milk output (and other factors) on individual farms over a period of time, as well as a means for relating changes in aggregate supplies to individual farms changes. Thus, panel data presents opportunities not possible with time series data, i.e., the estimation of changes in aggregate statistics. Furthermore, the type of data obtained over time from a panel of dairy farms documents the adjustments that occur on dairy farms and describes the mechanics of change in milk output. Panel data are useful in identifying and analyzing changes in resource use associated with change in milk production.

In addition to these description data that are generated over time, a producer panel also provides detailed data of the type required for a research technique such as the Markov process. The initial Markov matrix and transition probabilities developed from the producer panel data provide a wealth of information about the dynamics of changes in herd size and permit the examination of the crosscurrents of change taking place *within the overall trend.* The Markov process also can be used to generate distributions of factors other than size of herd. Crop acres, age of operator, or a combination of these factors with size of herd illustrate possible distributions. Production per cow and number of cows and the distribution of herd size could also be used to estimate total milk production. Producer panel data are currently being summarized on the changing land use pattern on dairy farms.

Panel data provide useful insights into dynamic aspects of dairy production, including importance of entry and exit of farms [7]. For example, in New York State, nearly 22 percent of the farms in production in 1960 had exited by 1965 and nearly 5 percent of the farms in dairy production in 1965 had entered during the previous five-year period. The data on exit and entry of dairy farms in the New York milkshed area and New York State illustrate the need for an explicit method for this type of data in designing a sample and in collecting and analyzing the data. A producer panel is one such technique of data collection. Estimates of supply response can be improved with accurate data as to the numbers of farms that enter the industry, leave the industry, and continue in the industry. The producer panel is a good method for obtaining these data for a fixed geographic area.

A panel of the Cornell type also is useful in conjunction with specific or general surveys, and farm account group data. The panel data, which is a representative sample, allow a perspective to be gained on the representativeness of the surveys and account data.

Data from the panel have been used as an input in a large-scale project designed to examine the agriculture in New York State toward the year

1985. Markov process analysis formed the basis for projecting trends in cow numbers and milk production.

Producer panel data also has been useful in testing various hypothesis concerning supply response. The magnitude of exit and entry and the relationship to farm size and resources and differing by size group and resource group have important implications for the changing resource base of representative farm studies. These data provided an opportunity to test the representative farm concept and the assumptions which underlie it [1]. The study suggested several possible ways in which classification for representative farms may be improved.

Future Plans

The future of the Cornell Producer Panel is currently under study. If financing can be obtained, current plans are to revisit the farms during the summer of 1970. Also, the Northeast Dairy Adjustment Committee has discussed the possibility of expanding the present panel to include the remainder of the Northeast region.

Farm Panels as a Source of Farm Management Data: The Ohio Plan*

E. T. SHAUDYS

FARM management surveys, cost route studies, and farm business analysis summaries were employed successfully as farm management data collection techniques prior to the decade of the 30's. Considerable debate about the merits of each of these techniques ensued. Costs, accuracy, representativeness, applicability, and information detail capability continue to be deliberated by farm management researchers.

Most farm management students are knowledgeable about the evolution and limitations of farm management surveys, cost accounts, and farm account record analysis and summary projects. M. K. Bennett and the Taylors have made extensive reviews of the development and evolution of these techniques [1, 2]. Farm operators and change agents working with farmers have benefited from much useful managerial information resulting from the employment of these information collection methods. Availability of information obtained from studies in which these data collection techniques were used has enabled farm operators, owners, and managers to make better decisions than might have been possible otherwise.

Ohio farm management personnel were involved in the developments and have used most of the data collection techniques cited. Development of farm firm structural changes, increased capacity to handle data, and more sophisticated programming and planning techniques, coupled with increased data collection costs have again caused us to seek data collection improvements. Need for specific operational and organizational managerial production transformation information has increased. Data users demand and need "up-to-date" and "accurate" information in order to use existing and developing data programming and processing capabilities in an efficient and useful manner. The continued quest for improvement and the increasing costs associated with data procurement have resulted in the development of the "farm panel" technique.

A farm panel is a purposefully selected group of operating farmers, who, with professional assistance, provide detailed business and operating information for a two- or three-year period. The panel is originated after a research need is carefully identified and sample criteria are established

---

* The author is indebted to R. H. Baker, R. H. Blosser, J. H. Sitterley, and others for reviewing this paper and for jointly guiding the development of the farm panel techniques.

E. T. SHAUDYS *is professor of agricultural economics at The Ohio State University and the Ohio Agricultural Research and Development Center.*

dependent on the research requirements. Typically, a purposeful sample of farm firm operators and/or owners has been used; however, most direct response sampling techniques can be used to identify the respondents.

Rigid sample criteria have been established and the respondents have been rotated off the panel and/or the panel discontinued as deemed desirable for the established research needs. For the Ohio projects it was originally proposed that carefully selected rotating participant panels be established and continued for each of the major farm types. Other panels could be established to procure data for specialty crops and minor enterprises as needs were identified. These panels would be continued for two years and then discontinued. For example, dairy, hog, cash grain, beef, and selected combination enterprise farm panels could be operated on a continuing rotation with vegetable, fruits, sugar beet, and other important but secondary enterprise types operated periodically. Within each panel the farmer respondents would be selected and rotated in accord with the defined need. This rotation of panel participants could be based on such criteria as facilities used, livestock numbers, cultural practices, geographic location, etc.

Area extension farm management agents serve as the local cooperator contact in Ohio. This important local contact relationship has been beneficial, resulting in realization of accurate and meaningful information flows. The area farm management agents have established a continuing relationship with farm clients and county agents and are amenable to a centralized research control. Both research and extension budgets contribute to support the project. A significant ancillary contribution has resulted in the wedding of extension with research interests and programs. The personal involvement of the area farm management agents has proved to be an important component in using the farm panel technique. Cooperation of farmers is much improved when the agent makes the direct contact and can provide useful information feedback to the respondent. Phone, mail, and personal contact with and through the research coordinator, area agents, and farm respondents has been developed in a meaningful manner. All the personnel involved appreciate their responsibilities and benefits; thus, cooperation has been excellent.

Empirical deviations have often plagued researchers in the assemblage of input-output transformation studies of farm firm activity. Some deviation results from variations in conditions beyond operational research data procurement control. Other variations may result from the desire to use particular production practices, equipment complements, and production procedures by a farm operator. Often the production methods used by the farm operator become routine; consequently, he may not realize the need to provide the detail needed by the investigators. Data gathering agents in frequent contact with respondents have a much higher probability of identifying causes and evaulating information deviations.

Samples have been purposefully selected within the established criteria. Lack of representation for descriptive purposes may be a shortcoming for some research needs, but no more so than with many other techniques. Voluntary samples and the non-response bias found in many farm surveys have caused data collected to lack the representative quality often sought. With the purposeful sample control, possible with the farm panel, the population can be accurately identified. Sample size as used in Ohio has been varied with the range in the control criteria. For example, in a two-year cost of cattle feeding study we used 91 records for the first and 77 records for second year of study. Sixty-seven records were used the first year and 81 for the second for a study of swine production. This study was designed to procure input-output transformation rates for the breeding herd to weaning and the feeding of market hogs. In a crop production cost study we used 33 and 47 records for each of the two years.

Our panel respondents provide a complete and detailed farm business financial record for the firm. We have used the Commercial Ohio Farm Account Book as the basis for the farm business financial record. Additional special data collection instruments are used for the collection of detailed physical and other operational information sought. The activity or enterprise can then be investigated during the course of the panel's existence with a more complete knowledge of the operator's and the firm's activities. The use of farm panels has provided useful data for many research needs that were not available in data collection techniques used earlier.

Farm data panels have been used in Ohio for hog, beef, cash crop, dairy, and some specialty farm production activities. Results have been good. Cost of acquiring input-output information has been less than for other methods we have tried capable of yielding accurate information. The use of carefully selected purposeful farm panels, coupled with a responsible personal proximal to respondent contacts and a centralized research control has yielded a very desirable result.

Schedules of input-output transformation have been generated in a most satisfactory manner. We believe the technique is a definite improvement over the survey or modified cost route survey method and plan to continue using farm panels for the procurement of farm production coefficient information.

Response Problems in Probability Sampling

JOHN W. KIRKBRIDE

"ONE of the curious features of statistics is that the more closely data represent the actual facts and the wider the appreciation of their accuracy, the more subject they become to criticism." This was an observation made in 1904 by Mr. John Hyde chief of the Statistics Division, USDA. He attributed this phenomenon to the fact that as their general accuracy is more widely recognized, data necessarily exercise a greater influence upon the markets, thus inevitably favoring or antagonizing those engaged in the game of agricultural production. Adverse comments of the losers are generally by far the most vociferous.

The present day economic structure feeds on a wide array of statistical facts. However, the statistical appetite of the economic society continues to demand broader coverage, greater detail, and increased accuracy. The use of objective methods of sampling will assist in bringing about improvement in accuracy. Probability sampling is such an objective method.

Probability sampling is an apparently simple term. Yet this appearance is deceiving and often leads to simplistic treatments that generalize too broadly, start from a doctrinaire position predetermining answers to problems, or concentrate on a single aspect of a survey to the exclusion of others. Probability sampling is a term of rich conceptual and empirical meaning; conceptually, it can designate statistical truth. It is not easy to conduct successfully in our pluralistic society.

Requirements

Probability sampling requires of each element in the population a known non-zero probability of being sampled; therefore, the implementation of probability sampling requires the establishment of a sampling frame. Frames may be characterized as accurate or inaccurate. In an accurate frame, all units resulting from the adopted definition of the population are included once and only once. Frames not meeting this criterion are called inaccurate. A common weakness in such frames is incompleteness. Seldom is the accurate sampling frame readily available. However, good sampling frames, properly constructed even though incomplete, have much potential for improved accuracy.

Constructing sampling frames to measure agricultural needs is particularly difficult—the number of establishments is large—change occurs daily —an increasing number of establishments are complex business enterprises

---

JOHN W. KIRKBRIDE *is director of the Survey and Data Division, Statistical Reporting Service, USDA*

interwoven with agricultural and non-agricultural activities. There is an increasing problem in defining the operator for these complex enterprises.

Coverage

Corollary with the requirement that each element in the population be provided a non-zero probability of being sampled is the need for each element selected in the sample to be represented in the survey results. Satisfaction of this requirement presents a challenge to the success of probability sampling. How to obtain complete response? Lacking that, how to provide accurate information for elements missing due to the absence of an informed person or outright refusal? Use aerial photography? Useful to the extent it is available and for selective items. Make ground observations? Limited to what one can see. Talk to relatives, neighbors or anyone handy and willing to talk? How reliable are responses to items such as intentions, living and production expenses, and income, that can be accurately supplied only by the operator? Lacking his presence or cooperation, how is this element represented in the sample? By substituting data from an establishment that responded and has a similar operation—or the one listed just ahead or behind the missing report—an average of a selected group of responses—the average of all responses—or is information manufactured based on all the threads of evidence that can be pieced together about the establishment? This is done, utilizing means that seem best for a particular situation. Can one have confidence in results derived from such procedure, especially results that include data imputation for a significant number of large operations?

One can speculate about the missing respondent problem in the future. Numbers of farm establishments are declining, though the current three million still provide a large population to sample. The trend toward commercialization and larger operating units gives substance to the idea that 300,000 farms will soon be marketing two-thirds of all farm products marketed. Shrinking the population to be sampled to about one-half million may mean a whole new ball game in data collection. Can information be imputed for one large operation? Will the trend to bigness lead to mandatory reporting—an unpopular term in the present climate of invasion of privacy?

Size Versus Response

Is there a relation between size of operation and willingness to cooperate? We think it is inverse, but the reluctance of large operations to cooperate may reflect a press for time, the multitude of inquiries received, and that they get involved in numerous surveys. Survey design and collection procedures need to recognize the many demands on this person but, if selected, there is no alternative but to attempt to get the facts about his operation. Otherwise, the survey results may not be accurate. What is the magnitude of missing reports in a probability sample survey? A conclusive answer may not be possible as the magnitude will vary with the survey and the population. However, a series of recent livestock surveys demonstrated a rate of about two percent in the smallest size group progressing through a rather uniform rate of increase to a level of 15 percent in the largest size group. Rate for the surveys averaged about six percent. These rates are disturbing, particularly rates in larger size groups that exert significant control over the total population. Data indicate the rate is increasing in larger size groups more rapidly than in smaller groups. Surveys that relate to crop acreage tend to have lower rates as the land use can often be observed by an enumerator. As an example, for the 1969 June Enumerative Survey, the refusal rate was 1.5 percent and the observed rate was 2.0 percent. It should be noted that the major thrust of the June Enumerative Survey is for crop acreage and land utilization. These items lend themselves to visual observation and measurement on aerial photographs.

Who Is the Respondent?

In mail surveys, questionnaires returned voluntarily are usually completed by the operator. Data for their farms should be accurate. Instructions for probability surveys stress that information should be obtained from the farm operator or other well informed person. Repeated contacts are required to meet this condition, but surveys with limited data collection periods may encounter operations where no one connected with that operation can be located. The enumerator must get it by the best means available. How much information is obtained through such means? For the 1969 June Enumerative Survey, information was obtained from the operator for 65 percent of the farm operations in the sample, nearly 11 percent from the operator's wife and about 7 percent from another relative associated with the operation. This frequently was a son or daughter. Hired workers employed on the farm made up two percent of the respondents. Thus, it can be assumed that information for 85 percent of the operations was obtained from persons well informed about the farm. Nearly 10 percent was reported by neighbors and about 2.5 percent by other persons in the area. Refusals and observed reports accounted for 3.5 percent. Again, the June Enumerative Survey may not be typical in view of the nature of much of the information to be obtained. Also, these percentages do not indicate the portion of the agricultural data represented by the 85 percent. But the results are indicative of the difficulty in obtaining response directly from the farm operator.

The Cost Alternatives

It is expensive to collect data by personal interview. A cost of $15 per personal interview is not unusual. Cost considerations focus attention on other methods of collecting data. Mail is a time honored method and is inexpensive. It is used extensively. Telephone interviewing is relatively inexpensive and is on the increase. What is the consistency of information provided by mail versus telephone versus personal contact? Evidence is accumulating in this respect as the combined tri-method of conducting probability sampling is expanded. There is reason to believe there may be a difference in level of reporting, at least for certain kinds of data. A recent livestock survey had about the same number of reports received by mail and by telephone. The mail averaged more livestock units per report than the telephone. The survey contained six size strata. Each stratum showed a consistently larger number of units reported by mail. Another survey relating to crop information showed no significant difference by the method of collection. Does this indicate that bias may be introduced for some kinds of information by the method used to collect the data?

The telephone also has the potential to increase the refusal rate. It is easy to terminate a telephone conversation by just hanging up the phone. This generally precludes further follow-up on a personal basis, and may trigger a position of permanent refusal on the part of the respondent. One cannot overlook the rather glowing reports of the success encountered by some that have used the telephone interviewing technique. We are optimistic that our endeavors will be equally as successful.

Trials, Errors, and Successes in Agribusiness Education at Purdue

JAMES C. SNYDER

THIS paper summarizes briefly our experience at Purdue in developing an agribusiness management curriculum. Specific educational goals of the program are given in subsequent discussion. Four overall goals represent our current thinking in undergraduate program development. The undergraduate curriculum should include:

1. A broad and liberal education in the social and natural sciences.
2. Adequate professional emphasis to enhance student placement and performance with business firms upon graduation.
3. Adequate academic emphasis to provide the foundation for graduate work in business management and/or economics.
4. Adequate agribusiness emphasis to provide the student with special insights into the unique problems of agribusiness without becoming involved with the specific trade practices and problems of any one agribusiness industry or job activity.

Overall graduate curriculum goals have emphasized excellence in academic performance, with sufficient applied problem analysis to acclimate the student to the workings of the business world. In this manner, both academic and industrial placement needs are met.

Undergraduate Curriculum Profile

The undergraduate curriculum emphasizes basic management principles and techniques useful in the managerial decision-making process. These are taught within the context of a broad academic base that provides a foundation for future growth and specialization. Based on a core course offering covering the major business functions, the curriculum encompasses a wide range of allied and underlying disciplines, of which economics is most heavily emphasized. Major features and structure of the program can be highlighted as follows:

(1) Training in agricultural economics and economic theory constitutes a fundamental foundation in the curriculum (22 semester hours).

(2) The agribusiness management core consists of four broad-gauge

---

JAMES C. SNYDER *is professor of agricultural economics at Purdue University.*

management courses that are taught within the department. Six hours of managerial accounting are prerequisite to these courses. The core courses —financial management, marketing management, production management, and policy formulation—permit rigorous exposure to the basic problems, principles, and approaches in each of these major areas of business activity. Specialized subjects such as advertising management, food retailing, and transportation are religiously avoided.

(3) A minimum of 28 hours in physics chemistry, biology, and related "hard core" science is required. This type of training provides some degree of science superiority over traditionally trained business students.

(4) To ensure a broad exposure to the social sciences, all business students are required to elect from 6 to 15 hours in *each* of the following areas: psychology; sociology; humanities; social, economic, and legal foundations; communications; and mathematics and statistics.

(5) Modest use is made of modern decision techniques. All students gain familiarity with linear programming, exponential smoothing, queuing theory, network analysis, and systems simulation. About one-half of the students gain some working knowledge of these techniques.

(6) Significant progress has been made in the generation of original agribusiness teaching materials, including case problems and computer oriented management planning and control systems.

It should be emphasized that the core courses are taught by members of our department. Extensive use is made of other departments, including those of the business school, for elective course offerings, but the student has his primary academic and counseling home within the department. In our opinion, it is unreasonable to assume that staff members not trained in business can plan and execute a business management curriculum wisely.

(7) The agribusiness curriculum is sufficiently independent to be identifiable as well-planned, high quality management training program, distinct from traditional agricultural economics. We attempt to hold for well-defined standards of performance in the core areas of business management. These standards have been fairly clearly established by the leading business schools, national studies, and general consensus within the business community. The agricultural label is sufficiently muddy without reinforcing past prejudices through uneven, unbalanced, and inadequate exposure to areas of study most businessmen consider important.

Undergraduate Curriculum Problems and Progress

The undergraduate program has been well received by students and business. Two major issues in the program involving both problems and progress relate to (1) the status of business management per se within an agricultural economics department and (2) the role of the underlying disciplines.

Recall that we have emphasized the idea of a well-coordinated core of professionally oriented business courses endogenous to the department. It has proven to be a good one. Departmental control can assure quality instruction and proper course content. In this manner we have provided a somewhat unique synthesis of traditional business management and modern decision theory within an agribusiness environment.

The essential problem in this approach has been one of staff continuity and training. Hiring and promoting staff people with an academic background different from traditional agricultural economics presents an administrative challenge. Moreover, the emphasis and content of truly management oriented courses is liable to be under question by those who view the world strictly in terms of economics

A second major area of both progress and problems is that of the role of the underlying disciplines. We are well pleased with the liberalizing influence that study of these related disciplines has brought to our students. We are much less pleased with the extent to which these disciplines have actually been integrated into the management decision-making process. Lack of integration and effective use of the behavioral sciences, economics, and mathematics is partially a function of the type of instruction and course content in the underlying disciplines as well as in the management courses. We have room for growth in both areas.

Graduate Curriculum Profile

Graduate training in agribusiness management is highly diverse. All students must demonstrate proficiency in agricultural economics and economic theory. Students choosing the business management specialty elect 9 semester hours of management courses at the M.S. level and 15 semester hours of management courses at the Ph.D. level. In actual practice, management training may be emphasized more heavily than these requirements indicate.

Considerable diversity of opinion exists among our faculty as to a proper curriculum balance between professional vs. academic emphasis. Most of our faculty do not favor a major emphasis on the professionally oriented business management courses, such as marketing or financial or production management. The priority of interest is in the development of research scientists and teachers and/or in line oriented personnel with research capability. From this standpoint, management science courses are more compatible with the educational philosophy of the department than the applied professional courses. Fortunately a wide range of both types of courses is available within the graduate business school. Additional management science courses are offered within the department.

The dissertation research for agribusiness students focuses primarily on management science projects conducted in close cooperation with agribusness firms. These cooperative projects require original contributions in management science that have current or potential application in decision making. Thus, the student is expected to demonstrate proficiency in both theoretical development and applied problem solution.

In addition to a successful wedding of theory and practice, this approach provides the student with excellent insights into actual business operation and management practice. Moreover, the nature of the research necessitates establishment of rapport with both line and staff people in middle and top management positions. In our opinion, these experiences are of major benefit to the student, whether he is interested in academic or business research or in line management.

In summary, then, our business oriented graduate student will be (1) well grounded in economic theory and its applications to agriculture, (2) capable of developing and using modern management science techniques, and (3) well prepared for either staff research or line management positions. Judged on the basis of industry financial support, student interest, and academic and industrial placement of graduates, there have been few problems to hinder our progress.

The Illinois Agricultural Industries Forum*

HAROLD G. HALCROW

THE Illinois Agricultural Industries Forum is a two-day seminar program for leaders and decision makers in the agricultural industries field. The program has been held each year for the last 11 years in late January or early February, except for one year. The primary theme of the Forum has been related to change in the agricultural industries or anticipated change, implications, and alternatives for development and public policy. Its first theme, in 1959, "Tomorrow's Farm Challenge to Food and Agricultural Service Industries," was an idea of interest throughout the succeeding decade. Themes generally have related to agricultural development potentials, to financing, new products, new systems, anticipated changes ahead. The Forum's theme this year was "Issues and Choices in a Changing Agriculture," as viewed by speakers, panel members, and other participants.

Purpose

The general purpose of the Forum is chiefly educational—to serve the 500 to 800 people who generally attend and to bring the results of the papers and discussions to a wider audience through publication and subsequent meetings. The program is designed to permit people to participate in open discussions about common problems. More specifically, the purposes are (1) to study, evaluate, and report changes in the techniques and management of resource use; (2) to consider problems and organization, operation, and changes in resource requirements of modern agricultural industries; (3) to anticipate direction and magnitude of change in size, organization, and operation of production units; (4) to understand changes in market organization techniques and to review changes in organizations and structure required to get products from the farm to the consumer; (5) to review changes in the agricultural input industries and alternatives for improvement in supplying resources to agriculture; and (6) to review alternatives in public policy as they pertain to changes or improvements in the agriculture industry and farm sector.

Program Planning and Development

During the first several years of the Forum, planning meetings were

---

[*] The assistance of E. E. Broadbent and H D. Guither was instrumental in the development of this paper. Broadbent served as the general chairman of the Forum during the first four years and carried the major responsibility for organization and development. Guither is serving as general chairman in 1969 and 1970.

HAROLD G. HALCROW *is professor of agricultural economics and head of the department at the University of Illinois.*

held in Chicago and St. Louis with representatives of industry and members of the department staff in agricultural economics. These were invitational meetings, sometimes with a luncheon or dinner sponsored by a bank, association of commerce, or some other agricultural industry interest. At these meetings suggestions were made regarding current major problems that needed discussion. Usually the general theme was suggested and approved, and committees were assigned to discuss further the program for each special interest area. Suggestions were brought back to the general college Forum planning committee and were refined and organized into the basic Forum program.

In recent years chairmen of the general and special sessions, appointed by the head of the department, have met as a committee and then consulted informally with industry leaders, either individually or in small group sessions and discussed themes, topics, and speakers for the various sections of the Forum. Other staff members have also been asked to submit names of potential speakers. Major strength of the Forum has been this personal involvement in program planning and in selection of knowledgeable speakers and panel leaders.

Program Format and Topics

The basic structure of the Forum is a combination of general sessions at the beginning and at the close of the two-day program and special group sessions representing commodities or special interest areas. Speakers and panel members are drawn from the staffs of the University of Illinois and other universities, state and federal governments, and industry.

The general sessions are planned to discuss current problems that hold a common interest for all segments of our economy. This year, for example, the general sessions discussed "Today's Problems and Alternatives for Agriculture as Viewed by an Economist, a Newspaper Editor, a Farmer." Another session considered "A Changing Agriculture and the Responsibilities and Needs of the College of Agriculture," and a luncheon speaker discussed "Issues and Choices for the Future of the Agricultural Industry." Other broad topics in earlier forums were "The Impact of the St. Lawrence Seaway on World Markets" and "Managerial Strategies for the '70's," including "Strategies for Rural Development," "Financial Strategies for Commercial Agriculture," and "Organizational and Operational Strategies." Topics sometimes range beyond the national situation; in 1967 the major theme was "Implications of the World Food Situation for United States Agriculture." The 1966 theme was "Financing Market Development" with related topics on "Expanding Role of Credit in Agricultural Industries," "The University's Role in Agricultural Finance," and "Capital Requirements in Modern Agricultural Business." A complete list of Forum themes over the years is appended.

The special group sessions are intended to bring more micro-economic discussions before smaller groups representing commodities or special interest areas, such as grain, livestock, dairy, poultry, farm supplies, food processing, building and equipment, feed and fertilizer, area resource development, and agricultural finance and credit.

Financing the Forum

The Forum is financed by registration fees and small supplemental appropriations from university funds and by use of university facilities for producing programs, papers, and publications. Those not on the program pay a registration fee, $6.00 in recent years. This does not include housing and meals. Convenient and adequate facilities are assured by advance registration. Block reservations are usually made at local motels and hotels.

A heavy commitment of staff and university facilities is required for a successful forum. The program can be made effective only if staff members are willing to invest time in organizing, developing, and promoting different phases of the program. People in agricultural industries and in the business community also need to contribute considerable time and enthusiasm if a successful program is to develop.

Opinion Survey

Participants at the 1969 Forum were surveyed to obtain their opinion about program and other matters. Two hundred and twenty-four participants responded: 59 percent were listed as managers, employees, or board members of business firms; 16 percent were farmers who were board members or officers of business firms or cooperatives; and the remaining 25 percent were trade association representatives, employees of government agencies, university staff members, members of the press, or unidentified. The majority of those attending had attended previous forums; only 38 percent of the respondents were attending for the first time, while 94 percent said they would like to attend future forums. Special sessions in grain marketing, finance, livestock marketing, and dairy marketing rated a high percentage of excellent and good responses. The general conclusion from the survey is that the program topics must be current and relevant to the interests of the participants and present ideas that are useful to those working in agricultural business and industry.

The 12th Agricultural Industries Forum is scheduled for February 3–4, 1970. The general theme will center around policy choices for agriculture and the implications for agricultural industry. The central idea is to view policy choices in relation to the growth and development alternatives in agriculture during the 1970's, the changes in structure that are likely to occur, and the alternative ways of organizing for efficient growth and development. Topics will relate to the money problems of agriculture, to anticipated developments in the managerial revolution, and to new ways of doing business in the agricultural industry field, including the increasing use of contracts, new roles for bargaining, and the like. We hope that many of you will be interested, and we invite you all to attend.

Conclusions

The success of such a forum program requires a number of things: (1) There must be a firm commitment by a significant number of the department staff; (2) staff members committed to work on the forum should have very good contacts with industry and must be respected for their leadership and competence in the area; (3) contacts with industry people should not be sporadic, and discussions concerning program and development of the forum should be undertaken in some depth; (4) thorough discussion of theme and program is needed prior to organization of the forum, with full consideration given to views of industry representatives; and (5) the concept of industry leaders working with university and government personnel is crucial in developing a spirit of cooperation and participation. American industry contributes to many educational and research activities. Participation in our forum provides an opportunity for the agricultural industries to make their contributions.

Themes of Agricultural Industries Forums, 1959–1970

1959	Tomorrow's Farm Challenge to Food and Agricultural Service Industries
1960	Planning for Dynamic Growth
1961	Meeting Changes in Agriculture and Industry
1962	Meeting Changes in Agriculture and Industry
1963	Projecting American Agriculture
1964	Building Markets at Home and Abroad
1965	The Market for Agricultural Industries
1966	Financing Market Development
1967	Implications of the World Food Situation for United States Agriculture
1968	Managerial Strategies for the '70's
1969	Issues and Choices in a Changing Agriculture
1970	Policy Choices and the Impact on Agricultural Industry

Extension Transportation Programs to Improve Marketing Efficiency

WESLEY R. KRIEBEL

MANY marketing firms face sharply higher costs of operation, due in part to the service costs and other problems of owning a truck fleet. Relief from these headaches is a strong selling point of the truck-leasing companies. Large-truck maintenance now surpasses 3.8 billion dollars annually, and delivery expenses in the urban environment are approaching $9 per hour. Profit-seeking managers are looking for ways to control transport as they control other production expenses.

Because transportation is not their primary business, many agribusinesses have limited management knowledge and capability in this field. Transportation expenses cannot be avoided entirely, yet few marketing firms know what it costs to own, operate, and maintain company trucks. Fleet records, if they exist, are usually incomplete, lack timeliness, and are too general for use in planning and effective decision making.

Furthermore, many agribusinesses need help as they search for more efficient assembly and delivery operations. Severe traffic congestion, restrictive unloading hours, small orders, frequent repeat deliveries, duplication of services, and cross hauling can become a managerial nightmare. Given the tools to work with, Extension marketing specialists can increase their contribution to improved food marketing in the area of transportation economics and management.

Management of Company Fleet Expense

Several demonstrations were conducted with marketing firms to point out methods of increasing managerial effectiveness over private trucking operations. We were able to document excessive and unnoticed repairs to individual vehicles. For example, one truck operating 27,000 miles in a 17-month period required three rebuilt engines at a parts cost of $867.67. In one dairy, we estimated the potential savings in repair costs at 25 percent. Needless to say, after top management verified their repair costs and considered the downtime involved, they became especially interested in fleet cost control.

Vehicle and fleet repair problems were diagnosed or confirmed by a truck manufacturer's service representative. Extension recommendations usually included preventative maintenance inspections and operations and the adoption of routine simple records and reports.

WESLEY R. KRIEBEL *is assistant extension professor of agricultural economics at The Pennsylvania State University.*

Results of the demonstrations were made available to at least 300 agribusinesses through a series of workshops held in Pennsylvania and nearby states. According to Extension commodity marketing specialists who assisted in the workshops, many companies were represented by operations people who have direct responsibility for fleet activities. Requests were received for additional information on fleet management. A publication, made possible through the Farmer Cooperative Service and The Pennsylvania State University, was developed to help those who wanted guidelines for controlling truck-operating costs [1].

Last year six Pennsylvania poultry processors registered 99 vehicles in a demonstrational truck-records program. This one-year program was designed to provide industry with data for review of maintenance practices on specific groupings of equipment, an indication of operational practices, and a basis for discussing specifications for new equipment. Each month individual truck operating expenses were recorded uniformly and mailed to the Extension Service. Cost per mile comparisons according to vehicle type, use, and age were developed. Cooperating firms requested expansion and continuation of the program for another year.

Management of Routing Company Trucks

In recent years there has been considerable development of mathematical procedures for more efficient routing and scheduling of trucks. Unfortunately, presentation of these techniques has often had a high "fog" index," so that the busy executive has been left confused as to how to apply them to his own operations.

Last year Schruben and Clifton [2] unveiled a truck-routing procedure that produced potential distance savings from 8 to 12 percent when applied to the actual routes used by agribusiness. While the theory involved rests upon mathematical analysis, the Lockset procedure can help dispatchers design delivery routes quickly and simply. Better procedures may improve services to customers, reduce delivery costs, and contribute to market development.

The Lockset method was field-tested with a Pennsylvania grocery chain to evaluate its potential in achieving economies in delivery operations. By this procedure, the stores and the vehicle to be included on a given route were selected and the most favorable sequence of stops determined. Ex post routing discovered by the new program were then compared with the actual delivery results.

The results were encouraging. Routes discovered by the new method produced potential savings every time. Top management, encouraged by the outcome, decided to implement the new system. Operations personnel concurred that the deliveries for the specific day were accommodated with one less truck and driver and 160 minutes less driving time. Savings were estimated at $70 for the day.

This venture turned out to be just the beginning. A traffic manager was hired to tackle immediately the most difficult problems in scheduling and transporting. His attention has been directed to advance planning, i.e., to establish optimum schedules for all delivery to 18 supermarkets and to develop and implement a program in fleet cost control.

A delivery strategy that optimizes delivery cost and frequency of service has probably not been achieved. Although solutions for three assumed patterns of produce and dairy delivery were compared using the Lockset method, the smooth interface of delivery with store ordering, data processing, and warehouse selecting has not been accomplished. Routing and scheduling decisions cannot be optimized when only partial physical distribution and information considerations are available.

The Lockset model can be used to explore the effect of alternatives, such as changes in vehicle capacity or availability, changes in demand patterns due to seasonal variations, or the addition of a new store or a new market territory. As with other operations research activities, complex systems are most easily handled with a computer.

Team Approach Essential

The demands by agribusinesses for answers to complex physical distribution questions require the team approach. Today's technological advancement involves teams of specialists; it can't be done otherwise. The industry can help by collecting and providing the input information needed.

If we are systematically to examine and contrast the performance of "what is" with "what might be," a coordinated approach to physical distribution and transportation problem solving is essential. In this way we are more likely to improve the performance of the agricultural marketing system by providing a more efficient transport route for agriproducts.

Education for Institutional Food Service—On Wheels

JOHN M. WELCH

IT gives me much satisfaction to be able, at long last, to bring to the attention of the agricultural economists of this nation some concept of a major market for agricultural products that has been long and flagrantly neglected, some of the vital characteristics of this market, and a suggested method of reaching the numerically largest portion of it through the Extension service.

I refer to the great market of public food service and lodging. It is defined as comprising all establishments serving food for immediate consumption and/or lodging accommodations outside of the home. This industry is the fourth largest in dollar volume of sales and the third largest employer of labor in the United States [1]. Its composition, in terms of types of establishments, is shown in Table 1 [3]. In 1966 it consumed agriculturally produced food products to the value of over 22 billions of dollars [4], and employed over 2.1 millions of people [1]. Its continuing rate of growth is shown in Table 2 [1, p. 3]. While no statistics are available for the acres of textiles that food service and lodging establishments consume annually in sheets, pillow cases, towels, uniforms, draperies, upholstery, etc., or for the miles of carpet they use, it is apparent from even a casual examination that this consumption must be a significant factor if the market for agriculturally produced fibers.

I am amazed and often disheartened that a market of this magnitude and importance for agricultural products has received so little attention from either agricultural economics or the Extension service. This neglect may be caused by the high segmentation of the industry, which is composed primarily of small volume units, largely independently owned and operated. For example, in my own state of Missouri, the composition of the food service segment for 1963 [5] is as shown in Table 3. It will be interesting to compare this with the 1968 Census when that becomes available.

Please note that of the 4,619 food service establishments open for the entire year, 708, or about 13 percent, had *no* payroll (i.e., were family operated), while an additional 2,000 had fewer than four paid employees. These comprise over 58 percent of the total number of establishments; and, while they made slightly less than 20 percent of the total sales, they are numerically a significant part of the market.

JOHN M. WELCH *is extension specialist in food service management at the University of Missouri.*

Table 1. Composition of the food service industry, 1966

	Establishments		Gross food sales		Daily transactions	
	number	*percent*	*billion dollars*	*percent*	*millions*	*percent*
Public eating places	343,749	93	18.5	84	85.6	82
Institutions	27,645	7	3.4	16	18.3	18
Totals	371,394	100	21.9	100	103.9	100

A 1960 survey of the owners and managers of restaurants in Missouri showed (1) that the average level of education was tenth grade; and (2) that success in the industry, as measured by unit sales volume, correlated at the one percent level of confidence with the formal education of the owner or manager [2, pp. 8–9]. It would appear that these people badly need educational and technical aid.

Furnishing this aid, however, is complicated by the fact that owners and managers, of the smaller places, which comprise the majority of the industry, perform a significant part of the technical or skill operations. Therefore, they find it difficult to absent themselves from their businesses to attend educational activities, even when such activities are highly decentralized to Extension centers. In this respect, they are quite similar to the small family farm with which the agricultural economist is familiar.

"If the mountain will not come to Mohammed, Mohammed must go to the mountain." In this case, if agricultural economics marketing education function is to reach these people, the Extension economist must go to their individual places of business. This has been a major problem in communication. It is complicated by the fact that each industry unit is in itself an entire marketing enclave. It receives raw or partially processed materials, transports, stores, processes, packages, sells, delivers, services, collects its bills, and disposes of its wastes—all within a small circumscribed area. It deals in the most perishable of products. Its timing schedule is arbitrarily fixed by custom in peaks and valleys of activity.

The extent of this marketing enclave indicates the number of managerial and technical skills required for success in this highly competitive in-

[a] These two categories comprise 58 percent of all establishments.

dustry—knowledge and skills that the great majority of its practitioners are seriously lacking. And this lack results in the high mortality characteristic of the industry.

When an Extension specialist does reach these people, it is a problem to have on hand the right forms, references, demonstration, instructional, and training aids to meet the specific problems of each individual.

While in Europe on sabbatical leave recently, I purchased a Volkswagen camper in order to be free of schedules and of the tyranny imposed by hotel reservations. Returning to the United States, I converted it to a mobile office-classroom. It is identified by a sign in the wardrobe window (next to the curb when the vehicle is parked) as the University of Missouri's "Food Service Program Mobile Consulting Clinic."

With its wide opening side doors, its work tables and utensil racks, backed by a refrigerator for perishable food supplies and supplemented by a two-burner propane stove, a complete set of cooking utensils, a ten-gallon water tank, and service for six persons, the mobile unit provides a facility for food production demonstrations.

A convenient electrical connection and an extension cord provide electricity for the operation of visual aid apparatus—projectors of all types.

The main cab seats five persons comfortably for small class work; its top is elevated to provide comfortable standing height for the instructor.

A folding table may be utilized for instruction in service or as a desk for managerial consultation.

Drawing equipment is carried for layout and design applications.

Library shelves have been provided in the rear compartment for necessary references, forms, tables, and texts.

Other equipment carried includes a portable typewriter, a compact dry copier, a folding work table, a small blackborad, and a small projection screen.

Equipment not in instructional use may be cleared from the main cab to the rear compartment, the driver's compartment, or to a hammock stretched over the driver's seat.

On occasion, the Extension specialist may use the comfortable bed for quarters, particularly when working in our beautiful Ozark vacation area.

I drove the machine with all equipment to this conference; it will be on display during the break, at which time I shall be glad to answer any questions about it and its use.

VIGNETTES: POLICY–PAYMENT LIMITATIONS

CHAIRMAN: JOHN O. DUNBAR, PURDUE UNIVERSITY

Payment Limitation: Effect on Supply Adjustment and Income Distribution*

RUDIE W. SLAUGHTER, JR.

MY assignment is to present in ten minutes some possible effects of farm program payment limits on production adjustment and income distribution. There is little time for preliminary remarks, but I must disavow any intent to state a case either for or against payment limitations per se.

Payments to farmers in our present set of farm programs have at least three functions: (1) compensation for public control of private assets, granted either voluntarily or otherwise, (2) income transfer, and (3) production incentive. However, the labels currently used for the several kinds of payment do not necessarily denote their function.

I am not aware of any precedent for, or egalitarian justification of, limitation of compensation for public acquisition of control of private assets. Surely, equity requires that such acquisition be fairly compensated.

A long standing precedent for limitation of income transfers indicates that farm program payments have been rationalized on other grounds. That these payments are now seriously challenged suggests that their original rationalization is at least suspect. Demands for across the board limits suggest that the challengers don't appreciate the diverse functions of the payments. It remains to be seen whether new programs now being considered will reflect recognition of the several functions of payments.

Production Adjustment Effects

From a preliminary analysis of 1968 program participation data, we can infer some effects of payment limits on production adjustment (as summarized in Tables 1 and 2).

Cotton

Table 1 summarizes the estimated impact on cotton production of three kinds of assumed limits at four levels. The estimates are based on

---

RUDIE W. SLAUGHTER, JR., *is an agricultural economist with the Farm Production Economics Division, Economic Research Service, USDA.*

hypothetical but, in my opinion, probable reactions of two kinds of cotton producers: (1) those planting only that cotton for which they receive a price support payment, i.e., the domestic allotment; and (2) those planting cotton for which no price support is paid. Producers in the first group, subject to a limit on total payments from all programs or total cotton program payments, are expected to forego diversion payments and plant the non-domestic portion of their cotton allotment to other crops as the limit denies them compensation for diversion. Additionally, I would expect that the portion of their domestic allotments for which the limit would deny them price support payments would be planted to other crops. These two actions are reported in Table 1 as acres released from cotton. The second of these actions would reduce cotton production by these producers, but this reduction would be countered with production increases by the other group of cotton producers.

Table 1. Estimated cotton production impact of specified farm program payment limits

Limit: kind and amount	Producers whose planted acres: Exceed domestic allotment: Number of producers	Exceed domestic allotment: Increase	Do not exceed domestic allotment: Number of producers	Do not exceed domestic allotment: Decrease	Do not exceed domestic allotment: Acres released from cotton	Net production effect
dollars		*thousand bales*		*thousand bales*	*thousand*	*thousand bales*
Total all programs						
3,000	34,800	864	34,200	1,170	2,764	−306
5,000	23,400	774	20,300	689	1,907	85
10,000	11,400	626	8,400	283	1,004	343
20,000	4,300	437	2,400	69	428	367
Total cotton program						
3,000	30,400	831	24,300	1,444	2,772	−613
5,000	19,600	728	13,400	1,012	1,960	−284
10,000	9,300	570	5,[illegible]00	530	1,044	40
20,000	3,500	386	1,[illegible]00	230	459	156
Cotton price support payments						
3,000	27,100	765	18,400	1,494	0	−729
5,000	17,500	663	10,600	1,058	0	−395
10,000	8,100	500	3,500	571	0	− 71
20,000	2,900	327	1,400	258	0	69

Those producers planting more than their domestic allotment would, I expect, forego diversion for payment as the limit reduces their total payment eligibility. However, rather than plant their previously diverted cotton allotment to other crops, they are likely to plant it to cotton. Hence,

Table 2. Hypothetical grain production response to specified farm program payment limits

Limit: kind and amount	Production increase		
	Corn	Sorghum	Wheat
dollars	*thousand bushels*		
Total all programs			
3,000	356,100	151,100	233,600

their cotton production would be increased. The cotton marketing quota would prevent them from planting more than their allotment acres to cotton. Thus, their action would not counter the cotton acreage released by the first kind of producer, although their increased cotton production would counter reduced cotton production of the first group. Payment limits below $10,000 tend to decrease cotton production, while those above $10,000 tend to increase it.

Feed grains and wheat

The hypothetical effects on the production of feed grains and wheat under three kinds of assumed payment limits at four levels are summarized in Table 2. The hypothesized reaction for feed grain producers affected by a limit is that those producers otherwise entitled to 150 percent of the limit would forego all feed grain program benefits and plant to feed grain an acreage equivalent to 120 percent of their feed grain base. For wheat farmers affected by a limit, the hypothesized reaction is that those otherwise entitled to 200 percent of the limit would forego wheat program benefits and plant acreage equivalent to 150 percent of their wheat allotment to wheat.

Both hypotheses are grossly over-simple. They are not intended as estimates of what would actually happen, but as illustrations of the probable different impacts of the three kinds of limits at varying levels.

In summary, production effects of payment limits vary by type and

Table 3. Gini ratios: Cotton, feed grain, and wheat program payment distributions, with and without assumed payment limitations, 1968[a]

Item	$3,000	$5,000	$10,000	$20,000	$30,000	No limit[b]
Cotton	.54	.61	.67	.71	.73	.75
Feed grain	.48	.52	.54	.55	.55	.55
Wheat	.53	.58	.6[illegible]	.62	.62	.62

[b] 1968.

level of limit and as price relatives and benefit relatives vary. Limits below $10,000 probably would impair the effectiveness of the wheat and feed grains programs in containing productive capacity.

Payment Distribution

Analysis of the effects of payment limits on the distribution of payments requires some speculation on the real effectiveness of the nominal limit. The simple assumption is that the nominal limit would prevent accrual of more than the specified amount of program payments to current program recipients. Though this assumption is naive, the resultant payment distribution is the one which would be revealed by program payment data. A more realistic assumption is that significant avoidance of the nominal limit would occur among those payees presently receiving small multiples of the nominal limit. I know of no statistical basis for estimating the extent of such possibilities.

If pressed for a judgment on the real effect of current payment limitation proposals, I would expect the real effect to be an increase in nominal payees with only nominal effects on payment distribution and no production effect discernible in the aggregate. Should the limits be made effective by law and administration, the major impact on distribution of income, in my opinion, would emanate from truncation of farm sizes at the upper limit of payment eligibility on cotton and wheat farms rather than from altered distribution of program payments. The same would obtain for any farms realizing a major part of their incomes from program payments. The structural effect of real payment limits on such farms would be similar to the structural effects of a limit on gross or net income.

Table 3 shows Gini ratios of program payment distribution made in 1968, and what they would be under assumed limits. The no-limit ratios are calculated with 28 strata. Each of the ratios under limit is calculated with fewer strata.

Payment Limitations: The Economic and Political Feasibility*

ARNOLD PAULSEN

IN an extreme sense, payment limitations are of course feasible. We can have them if we are willing to pay the political, administrative, and economic price. The U.S. economy and the federal budget would be affected less than one percent. The votes needed on congressional committees and on the floor of the House and Senate could, I believe, be obtained one of these years for some form and level of payment limitation if a coalition of administration and bipartisan congressional leaders are willing to give its passage sufficient priority. The U.S. Department of Agriculture could administer effectively and achieve the intent of any one of several forms of payment limitations. The question is not absolute feasibility, but relative desirability: Would the consequences of specific payment limitations be judged by our policy makers as improvements relative to what we have now?

Current agricultural payments are rather highly concentrated toward large recipients (Figure 1). The concentration ratio for agriculture payments in 1968 was larger than for the United States after tax income. The concentration of payments under sugar, cotton and wheat are more highly concentrated than feed grain payments (Figure 2). All payments were more concentrated in 1968 than in 1965. The concentration is really of no concern to the economic policy goal of resource efficiency for production of agricultural products, nor is it of any concern to the expenditure efficiency of idling agriculture's excess capacity. The concern comes from the equity goal, i.e., our concern that income and wealth are more unevenly distributed than we desire [1].

The Case for Payment Limitations

Payments could be limited in many ways; for example, for few or for many of agriculture's programs [7]. The commodity program of cotton, wheat, and feed grain are most frequently discussed, but wool and sugar, rice, and soybeans are also candidates. Payments under programs for land improvement (ACP) or land diversion (CRP, CAP, or CCP) could also be limited. Payments might be limited to each farm or to each individual producer (person) or to each family. The limit might be placed at

$20,000, or $10,000, $5,000 or $3,000. The payment limitation could apply only to price support direct payments (e.g. 14.74 cents per pound on 65 percent of allotment for cotton) [11], or be applied also to voluntary land diversion payments, (e.g., 50 percent of county loan rate times normal farm yield for wheat [10]. One could go on and limit the dollar volume of price support loans (e.g., $1.05 per bushel non-recourse loan on corn) [9], or extend the limits even to cost sharing payments for land improvement and conservation measures (e.g., 25 percent or more of the cost of providing more stock water on grazing land]. There are potentially a large number of possible alternative payment limitation plans.

Three schemes for payment limitations, representing radically different purposes and using different combinations of features, are listed below. They are arranged in descending order of total budget cost and tendency to preserve the status quo and in ascending order to their tendency to limit transfers in favor of the wealthy and give assistance to the very poor.

Plan A. A limit of some relatively small size, say $5,000, to any one farm for price support direct payments from each of the wheat, cotton, or feed grain programs.

Plan B. A larger limit, say $20,000 of total payments, to any one individual producer (a person) from all forms of agricultural payments, i.e., price support payments plus price support loans plus diversion payments plus cost share payments under all types of programs (wheat, cotton, feed grains, sugar, wool, peanuts, rice, soybeans, dairy, ACP, CAP, CCP, etc.).

Plan C. Establish a 2- or 3-billion dollar "negative income tax" for all

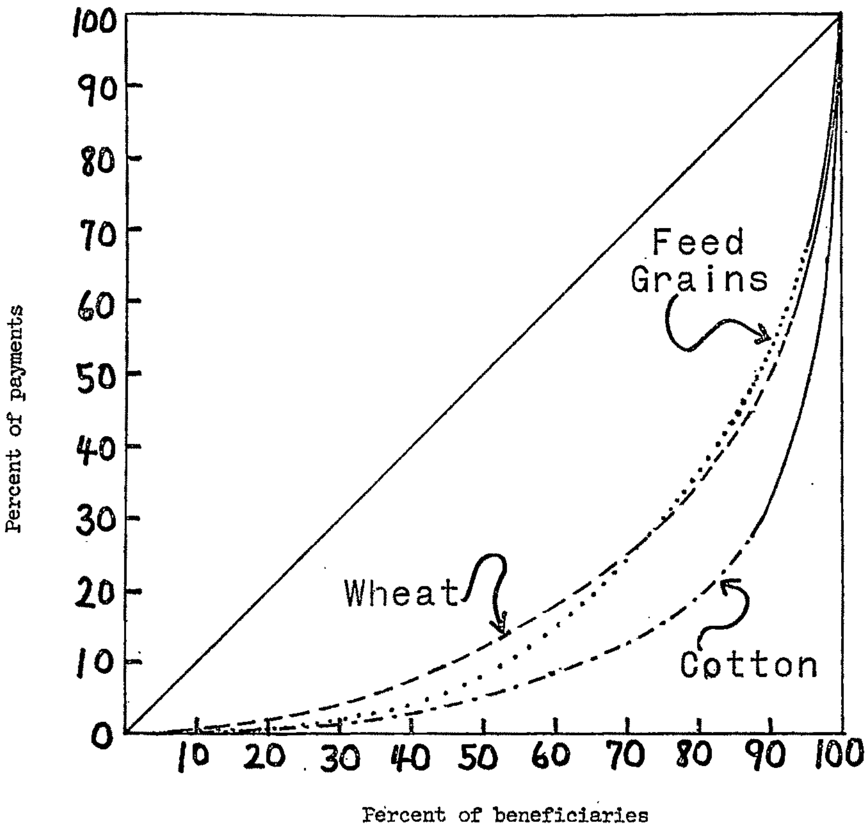

Figure 2. **Lorenz curves for cotton, wheat, and feed grain payments, United States, 1968**

needy farm families which would guarantee, say, $1,000 per year per dependent. Remove all other price support, land diversion, and investment cost sharing programs.

Plan A would reduce the range and average size of individual checks for direct income supplement. Probably fewer than 100,000 $5,000 checks would be required at first [4]. This would improve the public image of the agricultural price support programs. Individuals could still own several farms. It would still be possible, and not more expensive than now, to idle excess capacity through acreage diversion. It would be possible to support prices through production control and thus the United States could still strive for the standard of a rate of return for resources on large, well-organized farms equal to opportunity cost. The general price of land currently could be maintained. Government stocks could still be used to reduce price swings. The total treasury or government cost would be reduced. Smaller producers would still be able to participate fully in the two-price system now in effect. All could receive market prices at about the world level, but small farms could receive a price supplement by direct payment.

Plan B, with a $20,000 limit on all payments would result in only about 10,000 individuals receiving checks as large as $20,000 [5]. With high speed computers carefully compiling all payments to the same social security number, no one would need to receive more than $20,000 in total in one year through the Department of Agriculture. Two or more individuals of the same family could operate farms, of course, and each obtain a $20,000 check. With Plan B it would probably still be possible to idle enough total capacity by voluntary land diversion to maintain world price levels, but it might be slightly more expensive because fewer large marginal acreages that could be retired at low unit cost could be rented.[1] Land prices would fall, especially in areas of large holdings and specialized production of a supported crop, e.g., cotton or rice, with no close competing alternative [2]. The payment limit would become another restriction or resource for profit maximization, like land, capital, and labor. Farmers would need to learn to budget for the best use of their allotment of $20,000 of payments each year.

Plan C would place the entire basis for receipt of payments upon a criterion of need for disposable income. The poor would receive an income supplement regardless of what they produced. If his total income from all sources exceeded the poverty level, the large farmer would not receive any payment no matter how low farm prices fell. Under this plan it might be possible to completely free the agricultural markets for products and inputs from government intervention and do very little harm to small producers' level of living. If total incomes from all sources for a farm family, as reported on the income tax form, fell below the poverty level, a supplement would be sent to make up a portion of the difference between the earned income and a poverty line. The cost of providing income to the poor would be not over $1.10 for each dollar received, compared with $6–18 per dollar received now [11].

---

[1] This increase of supply control cost might exist only in theory because in actual practice the diversion payment recently has been nearly constant per bushel or bale of normal yield on all grades of land.

The U. S. excess capacity in agriculture could not be idled under Plan C, and full employment of agricultural resources would probably result. Lower product prices would follow but so would a strong competitive position for U. S. products in the export markets. With Plan C, generally lower land values would result, slightly lower consumer costs and a low rate of return to farm resources, especially on small poorly organized farms. Probably, resource return would also be below opportunity cost on large well organized farms, at least for a few years. Many land owners would find their net worth sharply decreased; some low equity farmers might even be bankrupt. However, the flow of farm products and gross national product and the purchase of most farm inputs would probably remain essentially unchanged.

A Political Deadlock Over Payment Limitations?

The clamor for payment limitations comes from a relatively new bipartisan coalition of large city congressmen who desire assistance for urban and low income problems and see large farm program costs plus payments over $20,000 as competitive for funds and as help for the rich rather than the poor. The resistance to payment limitations comes from the rural part of the west, southwest, and southeast. These areas and their representatives have respect for the big operator and for property rights and asset value. The commodities with most concentration are sugar, rice, and cotton, and the areas of most concentration of large-scale producers in general and especially of these commodities plus wheat and grain sorghum are in those dozen or so states rimming the United States on the west from Hawaii and California along the south to Florida and South Carolina on the east, plus Nevada and Arkansas. The senators and representatives from these states, whose large producers would be most adversely affected by payment limitation, hold influential positions on congressional agriculture and appropriations committees. Thus, while passage of payment limitations would seem to be quite feasible in a national popular referendum, it is not politically feasible in the agriculture committees and subcommittees of the Congress. A deadlock could develop if payment limitations cannot pass the Senate or congressional committees, and new farm legislation cannot pass the House without payment limitations next year [3].

Payment Limitation: Pros and Cons as Seen by Farm Organizations

W. E. HAMILTON

THE limitation of payments under government farm programs is a matter of concern to general farm organizations and organizations based on commodities with payment programs.

The National Association of Wheat Growers says limitations "would be unfair and discriminatory and would encourage widespread noncompliance and disrupt effective supply control" [3].

Delegates to the 1969 meeting of the National Cotton Council of America recommended that the Council:

> Oppose any governmental action which would place a maximum dollar limit upon any farmer's participation in, or benefit from, a price support program or payment program. . . .

This action was supplemented by the adoption of "guidelines" for future consideration and action which call on the Council to:

> Recognize that in the immediately foreseeable future, some form of cost adjustment must be provided in order for producers to sell (cotton) at a competitive price and receive a reasonable return for labor, management and investment;
>
> Provide that such cost adjustment be made to the commodity rather than to the producer, and that such adjustment be made on all bales actually produced on the acreage allotted for that season. . . . [4, pp. 4 and 3].

The Council, which includes processing and handling groups, apparently is more concerned with getting cotton produced than with the claim that limitations would "disrupt effective supply control." This view is clearly set forth in a statement by Council economists, Horne and Wellford:

> *Subsidy* is an ugly word, but the purpose of the subsidy is to help a great industry survive and work its way toward a better position by taking advantage of its tremendous opportunities to improve efficiency and expand markets. This kind of subsidy is needed just as much by big producers as by medium and small producers. It cannot be judged by the standards of a poverty program. The large producers, who get corresponding large payments, are not receiving any outrageous hand-out of government largess any more than the rest of the producers. There have been a number of studies by recognized authorities, indicating that the larger producers have no great cost advantage over efficient growers with

---

W. E. HAMILTON *is director of the research and commodity activities division of the American Farm Bureau Federation.*

> a few hundred acres. Since the subsidy is needed now to cover costs and a minimum return, a government policy withholding it from the larger producers would represent a government decision to put them out of business. . . . [2, p. 33].

The National Wool Growers Association views limitation proposals as "efforts to eventually kill present farm programs." It says that "limitations are economically unsound in any farm programs . . . and would create serious economic hardships" for wool. It also says that large flocks are necessary to provide economic units in semi-arid regions and that forcing large producers to liquidate would be inconsistent with the National Wool Act objective of "maintaining and increasing production of a deficit commodity" [7].

The National Sugarbeet Growers Federation takes the position that the limitation issue has been recognized by the scale-down provisions of the Sugar Act; however, it is opposed to any limitation. The Federation notes that sugar payments are made to producers for cooperation "in carrying out specific and well defined Governmental objectives," and says that an excise tax has been imposed on sugar to finance these payments and that a limitation would be "untenable" without removal or reduction of this tax [6].

The position of the National Grange is as follows:

> In order to have effective supply-management, we must have 'compliance' and participation by the producers of food and fiber, regardless of their size. The payments being made pursuant to the farm program are an integral part of supply-management and necessary to obtain producer compliance [5, p. 17].

The National Farmers Union favors a graduated system of limitations which calls for full payments up to $25,000, 75 percent of the next $10,000, and 50 percent of the next $10,000. This works out to a maximum total limitation of $37,500 for producers who otherwise would be entitled to payments of $45,000 or more.

In support of this position, Reuben Johnson, NFU director of legislative services, told the Senate Subcommittee on Agricultural Appropriations that:

> . . . we faced up to one of the toughest decisions that a farm organization like ourselves has had to make in a long time. . . .
>
> We didn't want to interfere with the workability of the farm commodity programs, yet we recognize we have a very serious problem, also somewhat political in nature. Therefore, we have decided on a graduated formula, to put a limitation on payments. It was a controversial issue at our convention, and there was a heated discussion of it [8, p. 1581].

The organizations thus far quoted generally favor existing government programs including direct payments. The American Farm Bureau Federation has proposed amendments to the Food and Agriculture Act of 1965 that would discontinue government payments and government supply-management programs for feed grains, wheat, and cotton effective with 1975 crops [1, p. 41].

Payments would be phased out by reducing the total amount used for this purpose for 1969 crops 20 percent per year for five years, with no limitation on payments to individuals during the phase-out. Effective with the 1971 crops, loan rates for wheat, cotton, feed grains, and soybeans would be limited to not more than 85 percent of the previous three-year average market price. Also effective in 1971, the government would be prohibited from selling CCC stocks of these commodities at less than 150 percent of the current loan rate plus carrying charges, except when sales are offset by equivalent purchases in the open market.

The Cropland Adjustment Program would be modified to require emphasis on the retirement of whole farms and the use of competitive bids to determine the land that is to be retired. The Secretary of Agriculture would be directed to retire at least 10 million acres per year for five years under this modified program.

A special transitional program would be instituted for farmers with gross annual sales of farm products of not more than $5,000 and average off-farm income of not more than $2,000 (including income of both husband and wife). Such farmers would be eligible to receive one or more of the following:

(1) Compensation for acreage allotments and base acreages surrendered to the Secretary for permanent cancellation.
(2) Retraining grants of not to exceed $1,000.
(3) Adjustment assistance of not to exceed $2,500 per year for two years.
(4) Loans under existing credit programs to further facilitate the transition of eligible farmers to more gainful employment.

Farm Bureau policy emphasizes the use of payments to get long-term adjustments in agriculture through land retirement and adjustment assistance to low-income farmers rather than to supplement commodity prices. This approach would largely, but not entirely, eliminate the limitation issue. The payments proposed to assist low-income farmers are relatively small. Payments made for the retirement of land on a bid basis would clearly be payment for performance, and the pressure for large units to participate would be much less than it is under commodity programs.

It may seem inconsistent to some that Farm Bureau should oppose limitations on commodity program payments when it seeks to phase out these programs. This is not necessarily so. Farm Bureau has long cited the "inevitability" of limitations as a reason for opposing commodity payments. It had argued that certain features of supply-management programs—such as acreage restrictions, the use of CCC stocks to limit price advances, the effect of guaranteed returns on per-acre yields, and the natural desire of administrators to protect themselves against responsibility for shortages—restrict individual opportunity and reduce farm prices below the free market level. The inclusion of limitations in such programs would be unfair because large operators do not have the alternative of producing for a truly free market.

In summary, organizations covered by this survey, with one exception, oppose the limitation of payments. The one organization that favors limitation supports a graduated system that would permit payments well above the $20,000 ceiling approved by the U. S. House of Representatives on two occasions. Farm organizations whose policies favor existing programs contend that government payments are earned by farmers. Consequently, they uniformly reject the type of limitations that would be dictated by the standards of a poverty program.

In its opposition to current programs, Farm Bureau argues that supply-management programs affect prices and costs in ways that make it unprofitable to produce without payments and that limitations would place a ceiling on opportunity in agriculture.

Consumer Knowledge for Sovereignty: Apples

LYLE SOLVERSON

IN the theory of consumer choice, the equilibrium solution represents maximum satisfaction because perfect knowledge is attainable and all alternatives have been considered. In real life this peak of satisfaction is out of reach because the typical consumer does not have available all the information needed to make such a decision. In the purchase of food products, the typical consumer does not have adequate information concerning quality, relative benefits of various brands and comparative nutritional values of substitute products. Furthermore, in the dynamic food industry, consumers would have to review and revise each purchase whenever any change occurred in the market, thus setting in motion an impossible information gathering procedure. Since securing additional information may be costly relative to benefits, the consumer operates with imperfect knowledge.

The question then becomes, what does the consumer base his choice upon? The information available to a consumer varies widely, depending on the commodity considered. One class of information is the objective but somewhat general reports from government or academic organizations.[1] For the most part, however, such sources tend to provide only background information and cover only a limited area of consumption expenditures. Information also comes from the less objective service publications, periodicals, and consumer testing organizations. However, none of these sources is systematically collected or presented in a form to meet the needs of many consumers. While both classes of information are available to all consumers, they are not generally used by the majority of consumers.[2]

[2] As an example, in the consumer interview conducted in St. Louis, Missouri, only 18 percent of the consumers stated they knew of any informational bulletins or pamphlets on apples.

LYLE SOLVERSON *is assistant professor of agricultural economics at Southern Illinois University.*

Table 1. Number and percent of consumers rating various purchasing characteristics very important, fairly important, and unimportant

Purchasing characteristic	Very important		Fairly important		Unimportant		Total	
	Number	Percent	Number	Percent	Number	Percent	Number	Percent
Lack of bruises	414	87.7	58	12.3	0	0.0	472	100
Lack of blemishes	294	62.1	159	33.5	21	4.4	474	100
Variety	285	61.4	142	30.6	37	8.0	464	100
Color	152	32.5	243	52.0	72	15.5	467	100
Size	66	14.0	273	58.1	131	27.9	470	100
Type of package	97	20.8	164	35.2	205	44.0	466	100
Brand[a]	48	10.3	86	18.4	333	71.3	467	100

[a] State of origin.

For the individual consumer, the most used and informative information is often his own experience with a given product. The importance of past experiences cannot be overlooked in analyzing factors affecting consumer choice.

This study dealt with the degree of importance of certain product characteristics in the purchase of apples. It sought to determine the relative importance of four kinds of attributes—quality, appearance, type of package, and "brand"[3]—in the purchase of apples. In particular, it was concerned with the relative importance of state of origin, or brand.

Source of Data

The data reported in this paper were collected through consumer interviews and mail questionnaires returned by the interviewees in six grocery stores in St. Louis, Missouri, during the spring of 1968. Additional data were collected by direct observation of consumer purchases within the same stores during the same time period.

Factors Considered in the Purchase of Apples

In the mail questionnaire, consumers were asked to rate seven factors that might have an influence on his purchase of apples: (1) lack of bruises, (2) lack of blemishes, (3) variety of apple, (4) color of apple, (5) size of apple, (6) type of package, and (7) state in which the apple was produced. Their responses are shown in Table 1.

Three of these factors may be considered as affecting or acting as proxies for quality and/or taste: lack of bruises, lack of blemishes, and variety of apple. These factors were considered to be very important or fairly important by 100 percent, 95.6 percent, and 92.0 percent of the respondents, respectively.

---

[3] Since a product may be differentiated by state of origin as well as by a brand name, "brand" is used here synonomously with state of origin.

Size and color of apples may be regarded as factors of appearance.[4] A smaller percentage of respondents considered size and color (71.2 and 84.5 percent, respectively) of some importance in their selection of apples.

Although the type of package is a factor not directly associated with the product, 56 percent of the interviewees considered packaging to be of some importance in their decision to purchase apples.

State of origin may be considered a factor not directly related to quality of product but may be one method of product differentiation. Only 28.7 percent of the respondents considered this to be an important factor in their selection process.

It appears from this sample that consumers put greatest weight on quality in the purchase of apples. Appearance of the product is also an important attribute, while characteristics external to the product (type of package and state of origin) are not as important in the consumers' decision process.

While the questionnaire results seem conclusive, Padberg et al. point out that problems may be encountered with consumer questionnaires "... when consumers are encouraged to explain motivations which they do not understand," or when "... questions may cause consumers to respond in a way that is different from customary behavior, in order to make their actions seem 'rational' " [1, p. 724].

Because of the importance to producers of the effect of state of origin on consumer purchases, the purchase of different brands of apples by consumers was observed directly. Red delicious apples of comparable size, quality and color were placed in a display with equal frontage given to the following three brands: (1) Washington Red Delicious apples, (2) Michigan Red Delicious apples, and (3) Red Delicious apples with no state of origin designated. An attempt was made to neutralize all factors affecting purchase of apples except state of origin. An audit was taken in each store at the end of each day. One observation consisted of the percent of apples taken per day of a given brand of apples. With equal display space and quality and equal prices, it was hypothesized that the sales of each brand would also be equal if there there was no preference for a given brand. Conversely, it was hypothesized that if there was preference for a given brand, the sales of that brand would be significantly higher than one-third of total product sales. The average percent of apples taken were: (1) 33.67 percent, Washington; (2) 33.61 percent, Michigan; and (3) 32.72 percent, unbranded.[5] Based on both consumer answers and observed consumer behavior, it may be concluded that state of origin appears not to have an influence on purchasing behavior.

---

[4] In some cases, these two factors may also be considered as proxies for quality.

[5] A one-way analysis of variance was used with state of origin as treatment. The *F* ratio was less than one and, of course, insignificant.

Conclusions

If the three factors, blemishes, bruises, and variety, do in fact represent quality and taste of product, and the other factors do not represent quality and taste to the consumer, it may be concluded that consumers put a heavier weight on quality and taste factors than on appearance and factors external to the product in making their purchasing decisions.

An important implication to apple growers, based both on consumer answers and observed behavior is that state of origin, by itself, has little effect on consumer purchasing decisions.

Louisville Produce Terminal: Its Changing Trends and Potentials, 1966-1975

B. Russell Robertson and Harold G. Love

PRODUCE terminals have long been an integral part of our agricultural system. It was there that producers could assemble and market their perishable products directly to various kinds of buyers. Over the years, produce terminals have been dynamic and colorful institutions rendering an essential service at competitive costs. Within recent years, however, the marketing system has been undergoing an evolution that is making marked changes in the way terminals do business.

The Louisville Produce Terminal is unique. It is not municipally owned or operated. It is a private corporation, with most of the stock held by firms operating on the terminal. Since its inception, the Terminal has experienced difficulty in determining whether its primary objective is to render some return to stock or to provide a least-cost facility for its tenant landlords. These two points of view are not entirely compatible.

Like many others, the Louisville Terminal continues to experience pains of competition and the shifting modes of doing business. In a sense, most terminals are relatively less important than they used to be. They have been displaced partially by another type of marketing system, because of (1) a shift to shipping point procurements by large buyers; (2) standardization of grades and packaging under the auspices of federal inspection; (3) forward pricing by large commercial farms dealing directly with large wholesale distributors; (4) centralization of district warehouses and prepackaging centers by corporate chains; (5) the decline of locally grown produce; and (6) the decline of "papa and mama" stores in favor of the supermarket. These changes are evidenced by the fact that the produce firms remaining in business on the Terminal tend to be larger but fewer. As firms specialize in products handled or services rendered, their sales volume increases. In the face of these changes, the management of the Louisville Terminal became concerned with the question of what lies ahead in the next decade.

As a result, the University of Kentucky Department of Agricultural Economics was requested to examine the demand and trends for terminal services, to delineate the market area, and to estimate its probable magnitude. To do this, commercial buyers and consumers were arrayed by zones radiating out from Louisville; e.g., Zone 1 embraced customers within a 50-mile radius, Zone 2 extended from 51 to 75 miles, and

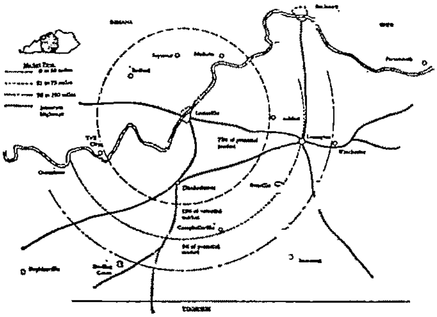
---

B. Russell Robertson *is extension marketing specialist and* Harold G. Love *is assistant extension professor of agricultural economics at the University of Kentucky.*

Zone 3 embraced an area 76 to 100 miles of Louisville (Figure 1). These zones, when analyzed in terms of number of consumers, indicated that 72 percent of the total population to be serviced by the terminal reside in Zone 1, 19 percent in Zone 2, and about 9 percent in Zone 3 [1]. The population in Zone 3 is declining as people shift their residence towards centers of business and commercial activities.

Income related to these zones was used as a measure of market size. In Zone 1, the aggregate income exceeded $1.8 million; in Zone 2, it exceeded $463 million; and in Zone 3 it was about $200 million [3]. Obviously, Zone 1, with its concentration of purchasing power, offered the greatest opportunity for market growth. Median family income ranged from $4,300 in Zone 1 to $2,600 in Zone 3 [4], again indicating the relative concentration of purchasing power by geographical zones.

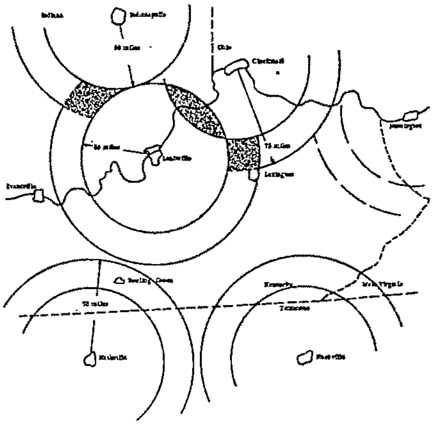
Figure 1. Percentage distribution of the projected 1970 market by market zones



The magnitude of the 1970 market can be estimated from linear projections using 1950–60 per capita consumption data and future population estimates. For the 1966–70 period, it was estimated that the market for fresh fruits and vegetables would increase by 52 million pounds representing a 9 percent increase to 634 million pounds. Obviously, the terminal corporation is interested in what portion of the estimated volume would move through the terminal rather than through some other distribution system. If the Terminal expects to capture an increasing portion of the market, each firm must recognize the question and aggressively serve the needs of its clientele.

Another factor affecting the terminal market is the number of retail stores in the market area that sell fresh fruits and vegetables. This number tends to decline as we move away from the primary zone. In 1966, the ratio of families per store varied from 160 in Zone 1 to 100 in Zone 3 [2].

Figure 2. Intermarket relationships and mileage zones



The study indicated growth would occur in public eating establishments, restaurants, drive-ins, schools, and institutional cafeterias. This expanding market sector will provide an excellent opportunity for aggressive service wholesale firms.

Size of orders were a major economic problem of produce firms. All too frequently, many terminal firms were hampered by small order deliveries, multiple stops, excessive handling, and pilferage, all of which eroded profits. There was therefore a need to analyze their physical distribution systems. As a consequence, some firms have changed their warehousing and handling methods, their modes of transportation and routing systems. These firms have reduced costs and, in many cases, customers have received an increased level of service.

We would be remiss if we failed to recognize the existence of intermarket competition, e.g., between Louisville and Cincinnati [Figure 2]. The market area was assumed to be primarily a function of distance. These boundaries are located midway between markets except when other factors such as quality of service or price and non-price concessions to customers pave the way for expanding the market area served. In these cases, a given firm can invade another market area. This has been happening in the Louisville market.

These are but a few of the highlights of the study. Although the findings indicate that the Louisville market will continue to undergo a significant change, they also foretell of opportunities whereby, sound, well managed, and aggressive business firms can achieve economic progress, provided they recognize the problems and proceed to solve them in a rational and economic manner.

The Economic Feasibility of an Integrated Broiler Operation

Richard W. Schermerhorn

THE objective of this paper is to discuss methodology used in conducting feasibility studies, using as an example an integrated broiler operation consisting of the following individual segments: a processing plant; a feedmill; a hatchery; a broiler production program; and a hatching egg production program.

Because of time limitation, I shall concentrate the discussion on the analysis of what I call "directly influencing factors." However, I should stress that in a complete feasibility study such general environmental conditions as population characteristics, community services, form of government and taxation, and the availability of education, health, and communication facilities should be analyzed relative to specific site location.

The analysis of directly influencing factors forms the basis of any feasibility study. It is generally required as a part of loan applications and is used to show whether or not the proposed operation can survive economically. Directly influencing factors are divided into three groups: (1) marketing; (2) raw material supply; and (3) production process. I shall limit discussion of the first two groups to a brief overview and place major emphasis on analysis of the production and/or processing elements of the proposed operation.

Analyzing the market feasibility of a project is usually the most difficult phase of the study. Usually, one prepares a comparison of local consumption and local production. However, we know that ready-to-cook broilers in ice or frozen form commonly reach markets within 1,000 miles or more; hence, we must analyze the national market situation, including production, consumption, cold storage holdings, and price trends. The difficulty in conducting the market feasibility study now becomes evident, i.e., the national and/or local market situation cannot insure that the firm can supply the quantity and quality of birds demanded by any given buyer, and the firm must deal with the buyer. Therefore, I generally interview prospective buyers and attempt to obtain commitments for the specified quantities and qualities that the processing plant will produce.

The second major item to be considered in any feasibility study is the economic availability of the various raw material supply items required in the operation. In the example "integrated broiler operation," it is a relatively simple task to insure, at least on paper, that these items are pro-

---

Richard W. Schermerhorn *is professor and extension economist in marketing management at Oklahoma State University.*

vided to the operation because the major input items to the various individual segments of the integrated operation are provided by one of the other segments. Further, it is relatively simple to determine the specific quantities of raw materials that will be required. For example, to produce 160,000 ready-to-cook broilers weekly will require the receipt at the processing plant of 165,000 live broilers; to produce this quantity of live broilers weekly will require a placement of 174,000 chicks weekly; to hatch 174,000 chicks weekly will require a weekly egg set of 210,000 eggs; and to set 210,000 eggs weekly will require a breeder flock of 83,000 breeder hens.

The economic availability of these raw material supply items for an integrated broiler operation depends primarily upon management's ability to schedule the production requirements of each segment of the operation and insure that this scheduling is carried out.

The third item to be examined in all feasibility studies is the production process itself, including an analysis of the availability of a dependable labor force, utilities, water, and sewage. Further, and most important in conducting any feasibility analysis, is a determination of the potential costs and returns that can be realistically achieved by the operation. To adequately determine this, one must determine capital investment requirements, operating capital requirements, costs of operation, and projected income.

In my feasibility studies, the following types of information are presented in the final report. First, operating cost budgets are presented; for the integrated broiler operation, this includes budgets for the processing plant, the broiler production program, the hatching egg production program, the hatchery, and the feedmill. A personnel projection need also is prepared for the entire operation—especially important today because many of our feasibility studies are conducted as a part of an Economic Development Administration or Small Business Administration loan. In these cases, the employment that the operation will generate in the area is one of the major factors determining whether a loan is granted.

Next, the data in the budgets are summarized to determine the specific investment needs, cost of operation, and cash needs. A projected income statement is then prepared to determine the profitability of the enterprise, and a cash flow summary is prepared in order to determine adequate levels of operating capital needed to insure the ability of the firm to meet its financial obligations. The projected income statement and the cash flow summary are, of course, the most important items in a feasibility study, both to the potential entrepreneur who wishes to analyze profit potentials and to the banker who has to evaluate repayment potentials.

The projected income statement is prepared from the operational costs and income budgets and shows the expected profit level for the operation. The level of profit will indicate the percent return on investment that the entrepreneur can expect and will show whether funds will be available to repay loans. The major annual income for the broiler operation would come from the sale of ready-to-cook broilers. In projecting this income, one must know the expected marketing weights and grades of the ready-to-cook broilers and the price variations by grade. Other sources of income would be from the offal produced by the operation, from the sale of spent breeder hens and cockerels, and from the sale of non-hatchable eggs.

With completion of the projected income statement, many feasibility studies are considered to be complete. However, it is my experience that the most important item has yet to be included—the cash flow summary. Adequate operating capital is perhaps the critical item for the successful operation of any firm, and this is certainly true for integrated broiler operations. Hence, it is necessary to prepare a cash flow summary to determine what the cash needs will be for the firm, and the sources of cash available to meet these needs. Usually a cash flow covering one year's operation on a monthly basis is adequate to show the cash needs and sources of cash available to the firm.

It should be emphasized that a cash flow summary must be complete; that is, it must include every item of expense and income to be incurred. If it does not, the firm may encounter great financial difficulty in a very short period of time. To illustrate the exactness that must be given to the preparation of a cash flow summary, I shall mention some of the items of particular importance in a cash flow summary for an integrated broiler operation: (1) chick placement schedule; (2) terms of payment by a buyer of the ready-to-cook broilers; (3) method and time of payment to the contract growers; (4) placement schedule for breeder hen requirements; and (5) credit terms for purchase of feed grain ingredients.

After all expense and income items have been considered, the real importance of a cash flow summary becomes evident because it allows one to determine: (1) those periods during which expenses will exceed income, pointing out the need for short-term cash borrowings; (2) whether enough operating capital will be generated over the long run to make loan repayments; and (3) whether interest payments on a particular loan can be met. I have also injected in some cash flow summaries, revolving fund situations which could provide additional types of financing for the operation.

In summary, a feasibility study must include an analysis of environmental conditions relative to site location, the market potential for the product, the economic availability of raw material supplies, and the profitability of the production process. The profitability analysis of the production process must include a determination of capital investment needs, costs and returns from operation, and projected cash needs and availability.[1]

Showing a Retailer that Meat Sanitation Pays—An Economic Approach

FREDERICK A. PERKINS

DEMONSTRATION, one of the oldest techniques of Extension education, is a most useful tool for implementing research findings into real world situations. Scientific research arouses interest and provides the basis for new developments. It also poses important considerations relating to the adoption of a new practice or procedure. Among these are the evaluation of income producing potentialities, the selection of optimum methods for implementing programs, and the creation of a favorable climate for employee acceptance of new ideas.

Extension marketing specialists can be effective in bringing about change by helping management to better understand and apply the results of research. The technique used, however, needs to be more sophisticated than the mass media approach of the past. More attention needs to be devoted to providing relevant information to key decision makers that is tailored to the needs of the individual firm. In many instances the specialist will require technical aid from other disciplines in order to provide total assistance to his client.

The following example shows how research originating at the University of Missouri is being applied to promote better handling practices for prepackaged meat in New Jersey supermarkets. Conceivably, a similar effort could be used with other areas of investigation where relevant information is needed for promoting new practices and educational programs.

Background

It is generally recognized that the appearance of prepackaged meat displayed in retail stores is of significance to consumers who presume color to be an indication of freshness. Discolored packages, therefore, must be promptly removed from the display case and reprocessed, thereby adding to operating costs. Basic laboratory work reported by researchers at the University of Missouri under a USDA contract reveals microbial growth to be a major factor causing discoloration. It further indicates that the display life of prepackaged meats can be extended by proper refrigeration and sanitation practices [1]. Increased display life can provide greater profits by reducing the number of rewraps, thus involving less labor, less material waste, and less product loss.

FREDERICK A. PERKINS *is extension marketing specialist at Rutgers University.*

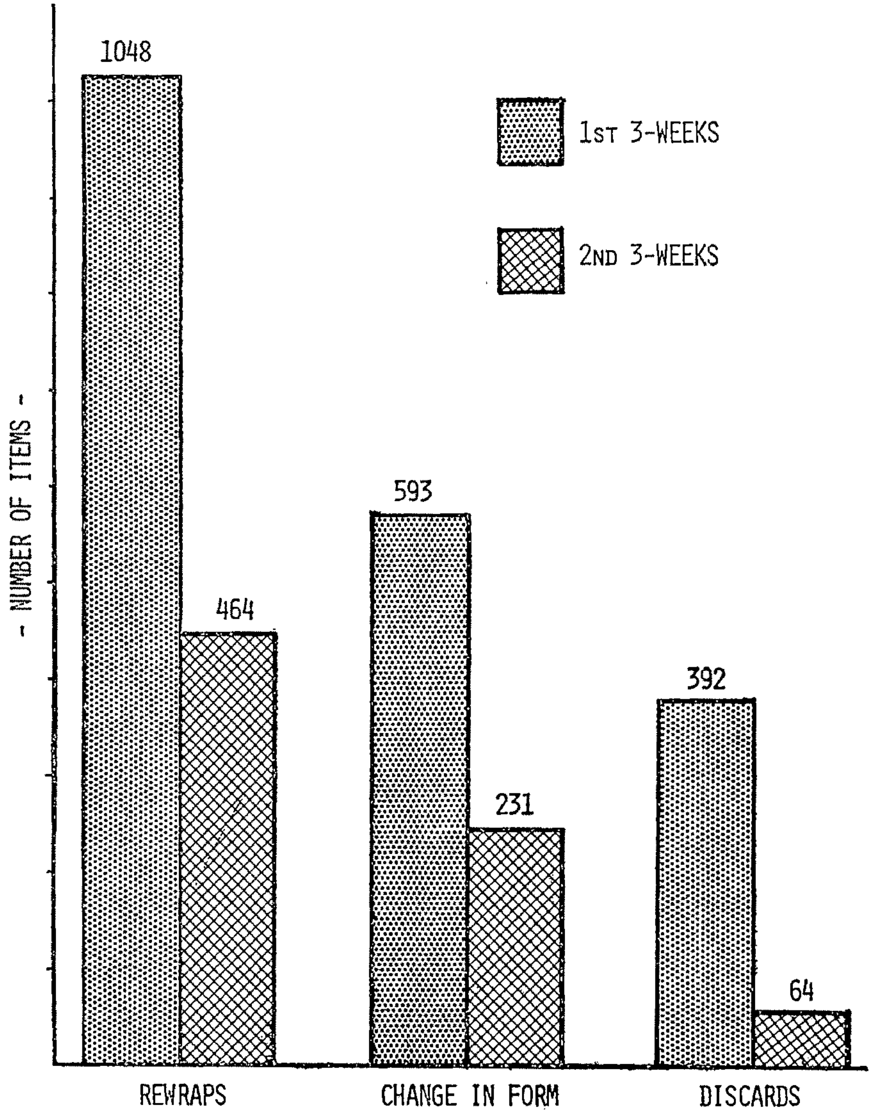

Figure 1. Comparison in number of items handled, by various categories, for two time periods

the product involved 362 fewer packages during the second time period. Weekly savings in product value for reprocessed items averaged $71, with a reduction of 61 percent in the number of packages handled.

Total gross savings for the second three-week period of operation was $757.

Net savings resulting from the sanitation-management program in the test store, after deducting costs, was estimated at approximately $169 weekly or $8,808 annually.

Incentive Program

Results of the study were reported to top management, who decided to implement a sanitation program in all it stores. Several meetings were conducted by Extension personnel and store supervisors to acquaint other employees with the program. To create employee interest in the program, the company sponsored a contest. Prizes and awards were based on criteria established to measure improved performance relating to how well each store put the sanitation program into practice. Also considered were resulting financial gains and overall improvements compared with past standards of performance. Winners of the contest were selected quarterly. The incentive program continued for one year to provide continuity and follow-through.

Conclusions

In the opinion of the author, similar reduction in losses and increased dollar returns as reported could be realized by most retailers who are willing to follow good sanitation practices, motivate employees, and manage their meat departments with the goal of maximizing profits.

Results obtained from this pilot study provide for a basic educational program in depth which can be extended to promote better meat handling practices among other food retailers.

It is hoped that, information on the case study approach will aid other marketing specialists to improve their teaching effectiveness and possibly stimulate other ideas for improved methods of implementing research findings.

THE ORGANIZATION OF AGRICULTURE

CHAIRMAN: MARSHALL HARRIS, UNIVERSITY OF IOWA AND USDA

Variants and Invariants in Comparative Agricultural Systems

FOLKE DOVRING

THE theme suggests a standpoint. Does agriculture have more invariants than other industries and other parts of society? The implicit standpoint is that it has. Its friends and admirers point to it as a stabilizing force in an unruly society, a bedrock of patriotism and good mores. Its detractors underline its seeming inertia, its sluggish reaction to innovations, its tendency to cling to outmoded ways of production and societal organization.

The value judgments rest on value systems, evidently; but before passing judgment, one way or the other, we should know the facts. Is the predominantly "invariant" aspect of agriculture a fact—or is it an optical illusion, and, if so, for what reasons? A question as generic as this one cannot be answered in the same generic form. It is necessary to examine some of the historical and contemporary evidence. The purpose is not merely an intellectual exercise. More than that, we need orientation for our thinking about the future—the future of the already high-income societies, which are about to enter developments without precedent, hence without direct empirical basis for expectations; and the future of the low-income societies, which may not merely repeat the past history of the advanced ones but may also leapfrog stages and otherwise telescope the known patterns.

The seeming inertia of "traditional" agriculture rests, in any event, on hindsight based on modern experience—over the last hundred years, hardly more. In the long perspective of the millennia, agriculture has been one of the most dynamic forces of human change; from the neolithic age to the Renaissance, most technical innovations of any consequence were agricultural innovations. Modern agriculture in advanced countries, again, is of course anything but static in its technology, productivity, and economic relationships; but many are impatient or uneasy about its institutional framework.

The stability dictum rests in fact mainly on observations about the institutional systems. At the center of agriculture's institutions stands the concept of tenure. It can be maintained as the centerpiece of a coherent analysis by regarding it, above all, as a system of decision making no less than as a device for distribution.

FOLKE DOVRING *is professor of agricultural economics at the University of Illinois.*

A Concept of Tenure

Tenure to what? Not just land, that is too narrow; ultimately we might talk about tenure to all the rights which the cultivator holds both as a producer and as a community member. The classical idea of fee simple or freehold was generated in the vacuum of abstract thought in the ages of enlightenment and classical liberalism, encountering the physical vacuum of the North American frontier.[1] The Middle Ages originally did not know tenure to land in any absolute sense; they knew tenure to specific rights, territorial or otherwise. The modern concept of "bundle of rights" again admits that separation of the sticks is normal, so much so that some sticks always (at least potentially) belong to the public powers.

Tenure in the conventional sense means one or more of three things: an opportunity to manage resources (on own account, in some sense), or an opportunity to perform real estate operations, or the right to receive rent. The first two regularly imply some degree of control (if sometimes only indirectly or negatively) of others; the rent receiving function does not necessarily extend beyond its own narrow scope.

The first category is the most important one in the study of comparative systems, and here we may expand the concept in the way indicated. Under resource management, we may discern several levels of decision making:

(1) Operational tenure, or the right to plan and execute day-to-day operations in the running of a farm;

(2) Production planning tenure, or the right to decide what to produce, when, where, how, and with what result, as far as that is within his power;

(3) Market planning tenure, that is, the right to decide or at least influence the terms under which firms may actually operate in the community or industry:

(4) Political tenure—participation in setting the ground rules under which economic decisions can be taken at the various levels.

The first two categories relate mainly to tenure as conventionally defined; the last two encompass the whole area of vertical integration with all its consequences for the actual meaning of the conventional tenure concepts.

The definitions of operational and production planning tenure shade over into the long question of "size of farm," which will be treated in the next paper. Part of the problem lies in defining: Size of what? Plantation or cropper unit? Internalities or externalities? Are work crews solely the "extended arms" of the central operator, or are they to some extent (what extent?) responsible, partly independent agents?

---

[1] Cf. [13].

Systems of control have their paradoxes. One of them is that the more narrowly control is conceived, the less efficient it sometimes becomes. For instance, the centralized Soviet system of State and collective farms leads to so much cheating at all levels that the central authorities in reality do not know what goes on in the country's agriculture. In Poland, by contrast, the operational decentralization of the small peasant farm system leaves agriculture much more open to inspection, hence more directly accessible to the kinds of control that really matter to planners at the national level.

Cultivator Control and Landlord Control

Cultivator control has culminated at two different stages of historical development: in the tribal village and in the semi-modern peasantry leading over to the modern type of family business farms, the latter type gradually surfacing in various countries as economic development proceeds. In between these two stages there have been various degrees of landlord control or even administrative control. In either case, the control of the peasant household was more in evidence on the production planning than on the operational level.

Landlord control sometimes took the form of large "manor households," as in Merovingian France and Saxon England and on many Latin American haciendas. On the whole, landlords did surprisingly little with their power to control the peasants. Most estate systems have been peasant farming under large-scale ownership, even when part of the land was under the direct management of the landlord or his agent. Their inefficiency was discovered in 18th century continental western Europe, hence the rising tendency for peasant liberation as typified by the Danish rural reforms beginning in the 1780's. The enclosures in England really flew in the face of this experience, and the compensating feature of some British landlords modernizing agriculture mainly through leasehold contracts has been vastly over-publicized [1]. Propaganda resulting from this English experience probably contributed to the expansion of latifundia in southern Europe and Mexico in the nineteenth century by the "privatization" of village commons.

Until recently, somewhat effective landlord control usually persisted in some of the situations where landlords were directly engaged in organizing the sale of products to markets outside the horizon of individual cultivators—thus, on the tropical and subtropical plantations, the Junker estates, and some of the south European and Latin American latifundia. In most of the grain farming areas of Europe and Asia, operational control (and often production planning control too) was ceded to cultivators, either by one leasing device or another or by outright ownership.

Under conditions of very slow-moving technology, and especially when population pressure was high, landlords and administrative authorities have had very little need to tell the peasants what to produce or how. The composition of farm rents and taxes was usually all it required to get the merchandise the markets wanted. The poorer the peasants, the more tightly they had to adhere to the going production system. The Communists in Russia never understood this basic logic of peasant existence, yet it is implicitly applied on the private plots. The present Chinese regime, facing an even tighter scarcity situation than the USSR did in the 1920's, also appears to be giving its peasants some more leeway.

As the time-tested efficiency of peasant farming shades over into the explicitly tested efficiency of modern family farming, let us remember that these systems both got established with very little help. Even in North America, the disposal of the federal domain created enough large ownership units to lay the basis for large-scale management if that had been in the cards, economically speaking [9]. Modern-time price supports have of course not been particularly favorable to small producers; yet, if anything, the prevalence of family-scale units is increasing in America and Europe—mechanization reduces the hired labor force faster than farm numbers.

Modes of Tenure

A connection between modes of tenure and the economic constraints that they occasion is often rather clearly visible when comparing the maps of tenure with those of farm types or specialized production areas. In the United States, the census maps indicate a connection between tenancy and field crops for cash disposal, while livestock areas and tree crop areas favor operator ownership. The validity of this observation is not even weakened by the fact that in some cases operator ownership is a managerial device to maximize the quality of work (the poultry broilers) or simply a means of spreading the risk (the Florida citrus groves).

Similar connections can be traced on the tenure maps of many other countries, e.g., several of those in Europe. On the face of it, it might appear that tenancy prevails where it always has ever since the medieval domain crumbled, but this only means that the best cash crop areas have remained such throughout the centuries. The converse truth is seen in the more outspoken subsistence areas of Europe (Norway, the French central massive), where landlords willingly sold out, on the strength of the "peasant rent" principle.

The inference is that the relative instability of short-term tenancy proves tolerable where the planning horizon is short and fixed investments of secondary importance.

The advantage of farmer ownership in providing security of planning is relative, because the situation leads to a recurrent drain on the farm's re-

Market Integration

The integration of individual production into large markets does not follow a single line of development from the subsistence household to the sophistication of today's urban society. Primitive societies had a great deal of local integration. The isolation of subsistence farming has been greatly overrated; even on very low income levels, peasant farmers nearly always produce some merchandise for a market. The increasing atomism of peasant farming in early nineteenth century Europe, for instance, did not mean that markets were served less well than before. Before prices began to fall in the 1870's, atomistic producer competition was necessary to prevent the starvation of cities.

Only under competition from cheap overseas produce did European peasants (and British landlords) begin to suffer seriously from their competition with each other. In England, this set off a long period of stagnation in agriculture. On the Continent, it became the starting point for farm cooperation.

Cooperation, to be effective, requires two basic conditions: market pressure under uneven bargaining position and a high degree of distributive equity among the producers [6, 7, 5]. It has accordingly been most efficient in Scandinavia, the Low Countries, Switzerland, Ireland, and lately also Japan. During the inter-war period producer cooperation also gained much ground in Eastern Europe. In the Soviet Union in the mid-1920's, farmers' cooperatives were well organized and even maintained their own trade missions abroad [11].

Cooperation was less successful in England and in the Latin countries than in Europe and America. The much more uneven property and farm-size distribution in these countries made the large landowners capable (or so they thought) of handling their own supply and marketing problems. In England and several commonwealth countries, publicly sponsored marketing boards have been established to assume some of the functions of cooperatives elsewhere.

There is a conflict between cooperative self-help and State support. Cooperation has reached some of its highest development in Denmark and the Netherlands, both of which until recently gave their farmers no price supports at all. In the United States, where depressed conditions came to agriculture only much later than in Europe, a promising start for farmer cooperatives seems to have been in part slowed down by the price support and other protective policy measures beginning in the 1930's. The same explanation may hold for Germany.

Credit, Price Supports, and Related Issues

Literature on economic development is nearly unanimous in repeating that peasant agriculture needs more access to credit. In specific develop-commented upon many times. They lead to special advantages of closeness and continuity and are the obvious reasons for the prevalence of cultivators' operational control. The differences in modes of tenure and type of tenancy also derive most directly from these factors and the specific risks which they entail. They also lend a peculiar dimension to the marketing and generally integration problems because the high risks would only be compounded if institutions were more volatile.

Factor proportions and relative factor prices have acted as brakes above all in the transition from traditional to modern technology. Given the fixity of the demand functions for food, the normal share of agriculture at different levels of per capita national product can be charted with some degree of confidence [2]. In the face of a storehouse of technically viable innovations, rates of substitution have quite rationally delayed the full-scale adoption of many of these innovations, as they still do in the low-income countries and many of those on the middle-income scale as well. Because of the basic nature of the relationships just mentioned, premature modernization (e.g., motorization) is done at the price of a very costly agriculture—in social account, at least. This is true whether the changes are rammed through by political authorities (the USSR, etc.) or adopted piecemeal by landed aristocrats lacking a comprehensive view of the whole economy. Economists pleading the agrarian-industrialist case in a capital scarce situation do not have the same excuse.

Inertia is often more apparent than real. The older stages of agricultural development have had fewer options than appears to the modern eye. The principle of "multiple lock-in systems" means that many situations which look inert to us have some hidden rationale that must be overcome before the system can be broken up or seriously modified.[3]

Nonetheless, a system once put in place tends to become a vested interest for those who draw more than average advantage out of it, and these people often include some of the most powerful members of the community. Thus, institutions have a built-in tendency to perpetuate themselves beyond the time when their original rationale has become obsolete. Possibly this tendency is accentuated in agriculture because of the virtually perpetual nature of the basic resource and the consequent fixity of its legal protection. Farm and property size distributions do appear to continue more unchanged over time than would follow from the needs of society; hence the pressure for land reform at certain junctures in development.

For the present low-income countries, it appears reasonable to draw certain lessons from at least the recent history of the developed ones (both free and Communist). The strength of small-scale, family based and cultivator operated farms is not only generally recognized in the free world but also, if grudgingly, in Yugoslavia and Poland; experimentation with small, self-reliant field crews in the USSR is an implicit concession to the advantages of closeness and decentralization inherent in the system of direct cultivator control.

---

[3] See, e.g., [10].

The application of experience from tenure systems is much less clear. It is difficult to argue that either owner farming or tenant farming is economically superior, from the viewpoint of society. The security of farm ownership hinges so much on other economic factors that the issue may have to be thought through afresh; the alternatives are either very long-term tenancy or some ownership construct similar to the Mexican *ejido*.

Also for low-income countries, the fostering of cooperation would seem to be one of the main roads toward farmer self-reliance and grassroots democracy. The outcome depends, for one thing, on the degree to which the peasants are prepared to receive and develop the idéa, and for another, on how essential it really is at the juncture when it is being launched. Ultimately the somewhat authoritarian character of centralized planning may get into conflict with producer cooperatives, precisely when the latter begin to be successful.

Toward the Optional Society

The lessons of the past are not as valid for the future of the high-income countries. The basic reason is in the widening range of options consequent upon rising productivity and per capita income. As W. A. Lewis has said so eloquently, the one aspect of development that renders it unequivocally desirable is the wider range of choice, hence the greater freedom, which it offers people [8].

Past periods, from the tribal village to "classical" or semi-modern peasantry, have had much fewer options. It is a misconception that archaic societies were more determined by cultural or social reasons and less constrained by economic ones. One does not have to swing full circle back to "dialectical materialism" to realize how many ostensibly non-economic institutions in traditional societies were economic ones in disguise.

At the level of affluence attained or attainable in a modern industrial society, the widening range of choices—for career alternatives and consumption alternatives–in the individual's life is quite obvious. A firm operating in a given societal setting may still find institutional constraints narrow and compelling; but for society at large, and for those who plan its future, wider choices are opening up. The higher the level of productivity, the less likely that it will hinge upon a precise set of institutions being maintained and established. There may still be choices that are unsuitable or clearly harmful; the giant farms of the USSR have still to show a profit. But among the classical alternatives (and some new ones, to be tested), the choice can increasingly be made on grounds other than that of economic necessity. Contrary to what Marxian dialectic assumes, the future becomes less and less "inexorable."

The point can easily be made in the case of American agriculture, for instance. Its share in the national product is already quite small and will, toward the end of the century, be so much smaller that widely differing alternatives of organization and institutional setup will not be noticeable to consumers. With a value product of, say, about one percent of the national product, agriculture may be a "ward of the state" or a "syndicate," and neither option has to be cumbersome. Whether farms are owned by their operators or by private landlords or by land trusts may be a source of convenience or inconvenience to operators, but society at large will not have to make the choice for them. Whether there are family farms or "factories in the fields" will affect productivity too little for society to object to the choices which are the farmers' own.

Precisely because the choices no longer hinge on compelling economic reasons, there is an increasing risk that they may be made for apparent ones. For instance, those who go on advocating "factories in the fields" might carry the day not because they are right but because they are believed. The leeway for propaganda is in fact widening with the options [4, pp. 359 ff]. The task of the economist is no less critical or beneficial because he sometimes can show that options are close to being equal economically. It should be no small triumph for "the dismal science" to be able to yield some of the stage to concerns which are closer to men's hearts than to their pocketbooks.

Economies and Diseconomies of Large-Scale Agriculture*

Philip M. Raup

THE American literature on economies and diseconomies of large-scale firms in agriculture is a curious mixture of riches and poverty. There are numerous empirical studies of size economies in agriculture, supplemented in the past decade by a growing volume of synthesized data, using simulation models and engineering-economic approaches [4]. But there are virtually no studies that explore in breadth and detail the problems that would arise if we had truly large-scale firms. The deficiency is easily explained though less easily excused. With a handful of exceptions, there are no truly large-scale firms in American agriculture. The few that exist are sensitive to investigation or study and remain generally inaccessible to economists and researchers if not always to *Fortune* reporters [3, 6].

There are no valid data on input-output relations, management problems, or marketing structures to use in synthesizing a 100,000-acre corn and oil-seed farm for Iowa, a 5,000-cow dairy farm under Minnesota conditions, or a 50,000-acre irrigated cotton farm in the Imperial Valley of California. Yet producing units (it is misleading to say farms) of these sizes and types exist in the Soviet Union India, in the Sudan, and elsewhere. It is not madness to suggest that they could develop in the United States, and some Florida, Texas, and California farms seem well on the way. The intent of this paper is to speculate (it cannot be more than that) on some of the probable consequences if they should.

A Brief Look at Available Studies

In summarizing studies of crop-producing farms (seven types of crop farms, fourteen different locations or situations, in five different states), Madden concluded, "In most of these studies, all of the economies of size could be obtained by modern and fully mechanized 1-man or 2-man farms" [4, p. 54]. Larger farms might increase total profits but would not result in lower average costs. Within the range of farm types studied, efficiency in resource use was thus largely irrelevant as an argument for increasing farm size above a two-man scale of operation.

---

* Paper No. 7044, Minnesota Agr. Exp. Sta. Scientific Journal Series. In developing this paper I have benefited greatly from discussions with Boyd Buxton, William Elder, Paul Hasbargen, Harald Jensen, Max Langham, Vernon Ruttan, John Sanders, and Richard Wagner.

Philip M. Raup *is professor of agricultural economics at the University of Minnesota.*

The acre size involved covered a wide range.[1] In California cling peach production, lowest average costs were achieved by orchards of 90 to 110 acres, if mechanized. In market vegetable crops, farms of 640 acres were almost as efficient as farms up to 2,400 acres and above, if use could be made of custom work for field operations.

In other California field crops, lowest average costs were attained by farms in the 600 to 800 acre range, producing some combination of sugar beets, tomatoes, milo, barley, alfalfa, and safflower. Average costs began to rise slightly for farms of this type above 1,400 acres in size, and (in another location) for farms above 3,000 acres in size, when cotton was included as one of the crop alternatives. For irrigated farms specializing in cotton, the most efficient California farms required four men and 700 to 1,400 acres (depending on soil type). In contrast, Texas irrigated cotton farms achieved lowest average costs with one-man operation on 440 acres. For wheat in Oregon, the one-man unit with 1,600 acres was also as efficient as larger farms.

Van Arsdall and Elder in Illinois used a simulation technique and linear programming to explore economies of size for cash grain and hog-producing farms over a size range requiring one to six men, with various combinations of four-, six-, and eight-row equipment [10]. Total acres ranged from 574 to 3,937 in the cash grain area and 355 to 2,104 in the hog area. Gross income ranged from $54,000 to $438,000.

In cash grain production (corn and soybeans), the efficiency reached by an optimally organized two-man farm, using eight-row equipment on 1,641 acres, was as great as that achieved by larger farms of up to 4,000 acres. In hog production, lowest average cost was achieved by a two-man farm using six-row equipment on 716 acres. Farms of up to 2,000 acres requiring a capital investment of almost one million dollars were included in the model.

In both cash grain and hog production, the efficiency achieved by one-man farms using eight-row equipment was almost as great as that computed for two-man farms, leading Van Arsdall and Elder to conclude that ". . . any size of farm considered in this study can compete effectively with the optimal two- or three-man units" [10, p. 53].

Although research methods and procedures differ, above a two-man scale of operation the studies show no significant economies or diseconomies of size throughout the size ranges studied. They leave us with no guidance to the central question asked in this paper: What are the economies and diseconomies of really large-scale farms in American agriculture? The question cannot be answered from available empirical data at the firm level.

---

[1] The summary data that follow are from Madden [4].

What Existing Studies Do Not Tell Us

In all of these studies the focus has been on efficiency in resource use and on profit. It is remarkable that none of them has considered the after-tax position of owners and operators, thus ignoring the question of income tax policy as it may effect farm management decisions. For truly large-scale farms the after-tax position is crucial to the analysis.

Another serious defect of studies of economies of size is their static nature. With few exceptions, time is not a variable, in the sense that the growth pattern of the firm over time is excluded. Studies of firm growth are currently fashionable, and good recent reports are available [1, 8, 11]. Although a beginning has been made, key questions remain unanswered. What sizes and types of firms are most likely to survive a variety of simulated shocks or crises? In what size or structure of firm is the capacity and incentive for internal saving and investment maximized? How are the benefits of growth distributed among labor, capital, management, and entrepreneurship?

Most existing studies provide little information about the capacity of firms of different size to adjust to rising land values. Van Arsdall and Elder did explore this question, with some surprising results [10, pp. 39–41]. The study was programmed with land values at anticipated 1969 levels of $491 per acre in the cash grain area (East Central Illinois) and $332 per acre in the hog area (Northwestern Illinois). As a part of the simulation study, land values were permitted to vary from $491 to $1,353 per acre in the cash grain region and from $332 to $848 per acre in the hog area. At simulated land prices above about $850 in the cash grain area, grain crops were forced out of the program, and livestock (hogs) took over, based on purchased feeds. In 1969, land prices are in the $800 per acre range in East Central Illinois, yet corn and soybean production continues. We can only speculate on the compensatory adjustments taking place within firms.

Few of the studies surveyed provided for "growth" in management skills over time. Most of the studies, in fact, regarded management as a fixed cost or "fixed residual" over the size ranges studied.[2] As farm size increases, management becomes a critical cost item. Management skills must be learned, and producing a superior manager is expensive. To discuss the efficiency of farms of alternative sizes without allowing for the differential costs of producing the managers, plus costs of management error, feedback and growth in skill, is to ignore one of the most important aspects of transition in size of farm.

---

[2] An exception is the study by Moore [5]. Labor supervision was charged in at the flat rate of $720 per man for farms ranging from one- to eight-man in size. The Ph.D. thesis by Thomas [8] is also an exception, in that specific allowance was made for increases in efficiency and output over time, due to improvement in managerial skill.

A potential advantage of large firms is greater capacity and flexibility in the purchase of management services. A scale large enough to justify employment of a resident nutritionist, entomologist, veterinarian, accountant, or tax consultant may be a critical measure of optimum size in some types of production. These services can also be retained under contract, but small farms typically do not have this capacity. Existing studies of size economies rarely include any discussion of the variable costs and returns for this aspect of the management input. Neither do they explore the possibilities that this source of potential economies of size might be made available to family-type farms through cooperatives or other forms of joint or communal enterprise. In theory, management services of this type should be among the most divisible of inputs. The farm operator ought to be able to contract for an hour, a day, or a week of these services. In a few places this is possible, but in practice they tend to be very lumpy inputs, available principally to the larger farms.

Big farms also achieve economies of size in bulk purchasing of fertilizers, chemicals, machinery, and other conventional inputs. On very big farms the cost of these inputs may be significantly lower than on one- or two-man farms, yet most studies have used constant prices for inputs in testing for economies of size. In this sense, available studies may understate the cost-reducing advantages of large farms.

Possible Diseconomies of Large Size

When firms grow very large, new problems emerge with regard to level of operation. In theory, a firm will vary output and factor proportions as prices change. One of the handicaps of the family firm is that it is often unable to behave in this manner, especially in the short run. Factors are committed to the production process and have a short-run marginal cost of zero. The family farm cannot fire its labor force and often has only two alternatives: operate at capacity or quit. Large, specialized firms in near-monopoly positions and faced with sloping demand curves may also in practice have only two choices: close the plant or operate it at capacity. Thompson and Proctor found this to be the case in a simulation study of a non-farm monopoly for which the product's demand was responsive to advertising [9].

The output responsiveness of large-scale firms to price change may thus be erratic, leading to large discontinuities in supply and in local employment. The response of organized labor in industry in similar situations has been to insist on stability-of-employment contracts. This is almost certain to occur in agriculture if large-scale firms develop. If fixed costs are a large part of total costs, and if labor contracts prevent layoffs, the net effect is to hold the firm at capacity operation long beyond the point at which marginal cost pricing would dictate a reduction in output. The large-scale firm in this respect may be comparable to the family farm in that its realistic options are to work at full capacity or close plants.

A major difference lies in the probability that the large firm would elect to increase its advertising budget rather than close plants. In the past, agricultural products at the farm level have been relatively undifferentiated. If production is controlled by a few large firms, this is almost certain to change. Where large firms are now important in the production of certain products (some fruits, nuts, and vegetable crops), we can already see the development of large-scale expenditures on advertising designed to create the illusion of differentiation. If this occurs, non-functional advertising will be an added measure of the diseconomies of large scale.

Another major difference lies in the fact that the quitting process for family firms is made up of many small withdrawals spread over time, allowing gradual adjustment in the communities and the industries involved. If a large plant is closed, it is a traumatic experience for the community. The reaction involves protective measures by the labor force and the community that become a major restraint on management decision making.

Large farms in the 50,000- to 100,000-acre class would also face problems with costs that are external to the small firm but internal to the large firm, including health, welfare, recreation, and a host of other responsibilities. The best illustration is provided by the experience of collective and state farms in Eastern Europe and the U.S.S.R. A major part of the farm manager's problems involves education, health, welfare, and maintenance of the local infrastructure. For example, in one large collective farm in the U.S.S.R. the account records revealed that farm road construction and maintenance costs in 1967 were over 200,000 rubles, equivalent to 21 percent of farm profits.[8]

The example reminds us that there are economies and diseconomies of size that can be measured only in terms of political or social welfare. Big firms in dispersed locations tend to dominate political processes. They either *are* local government, or control local government. There may be size economies in the provision of public services in a company town, but the price is often a stunted local political life. This emphasizes the fact that economies of size of big firms are often measurable, while diseconomies are typically intangible. It is not just magnitudes that differ; it is measuring scales.

This is nowhere better demonstrated than in problems of pollution control and environmental protection. The seriousness of these problems increases with size of firm. Manure on most family size farms is an asset; in very large feedlots, it is a liability. To date large firms in agriculture have often succeeded in evading responsibility for their contribution to pollution problems. This cannot continue. A major cost item for large firms in agriculture in the future will be for environmental protection measures that have been avoided to date or that are largely unnecessary when production is diffused over the landscape.[4]

---

[8] Interview with Director, Kolkhoz "Kirov," Krasnodar Krai, U.S.S.R., August 30, 1968.

The Potentials of Market Power

We have almost no data that show the existence of economies of size in a technical or production economics sense for farm sizes above the two- to four-man range. There are data that suggest that, above this size, potentials for size economies lie largely outside the firm. The tentative conclusion is that, if big firms emerge in American agriculture, it will be due to market power, in both factor and product markets, and not to production efficiency as conventionally measured.

The potentials for exercise of market power lie in three major areas: power to control supply, power to alter demand, and power to attract capital. Within the limited scope of this paper it is possible only to outline the major issues associated with size economies achieved in these ways.

Private firms or groups of firms large enough to control agricultural production would no longer be private. Control on that scale can be enforced only by a take-over of some of the powers of government. If this occurs, it makes a mockery of any attempt to measure economies of size in a conventional sense. The price signals in the market place would be falsified, representing not true costs or marginal value products but the rewards of an arbitrary reallocation of rights. Agricultural supply control in a democracy can be only a political decision, to be resolved by political processes. The production efficiency of various sizes of farm firms should be considered in making that decision, and for that the studies reviewed in this paper provide guidance. But the procedure cannot be reversed. Rights to control supply cannot first be acquired by private firms or groups, followed by attempts to measure economies of firm size. That answer is determined by the allocation of the right of control.

The power to alter demand is typically represented by advertising. If new and better products can be introduced to a wider market, advertising can play a valuable economic role. Given the low elasticity of demand for total food in the United States, it is difficult to see how a structure of farm firms large enough to command advertising budgets on the scale needed to influence demand could serve any economic purpose. We have little evidence of production economies to be achieved through larger firms.

---

[4] Environmental protection will be an item of increasing cost for agriculture in the future, whether or not production is concentrated in large firms. The magnitude of the cost item, however, will almost certainly be greater for large farm firms than the sum of the costs for small dispersed firms. This seems to be a clear case of diseconomies of size and concentration.

Economies of size do exist in processing and distribution, but it is not clear that these firms need to be integrated with production at the farm level. A large retailer may desire to obtain his supply from a large processor at specified qualities and known prices. The processor, in turn, may find it rewarding to control a part of his supply as a bargaining device in negotiating with farm producing firms. But the history of processor-producer integration is not a unilateral record of a take-over of control of farm production by processing firms.

This brings us to the question of power to control capital, which Shaffer has rightly stressed as one of the most important factors in determining the control of farming [7, p. 256]. Much of the capital in American agriculture is held in use by a combination of inertia, lack of information, and the difficulty of making occupational change. Over time, this capital may be replaced by other capital, attracted by rising land values and by institutional defects that result in favored treatment for certain classes of investors. The method by which we tax capital gains is an example. The increase in rural land values in the United States over 35 years has generated an expectation of continued increases. Inflation has reenforced the interest in land as an inflation hedge. This attracts capital from individuals less interested in current income than in capital preservation, or appreciation.

The owner or investor who can afford to forgo annual income in favor of capital gain can accept low annual rates of return while receiving competitive rates of return over time. If the nominal owner is heavily mortgaged, his return through capital gain may be especially high when computed on the base of his actual equity. High leverage and capital gains on the scale experienced over the past decade can convert a nominal rate of return on total investment of one or two percent into an effective rate of return on equity of eight to ten percent, or higher [2].

It is not only wealthy individuals who benefit in this way. Much of the cost of supplying land capital to American agriculture is apparently being carried by those who have left the farm but are willing to leave the operation of their share of the family estate in the hands of a farming relative or neighbor. Family sentiment, fear of inflation, hope of capital gains, a desire to hedge the uncertainties of non-farm jobs, or psychic rewards as landowners account for the commitment of a significant portion of the land capital now employed in farming. Just how large this is we do not know, and measuring its magnitude and mobility (or immobility) is a challenge to our research.

Capital is also being held in agriculture by government policies that affect the size of farms. Economists perpetuate the myth that one dollar is like another dollar in calculating costs or prospective rates of return. This is obvious nonsense. A dollar of property tax costs is unlike a dollar spent on labor or fuel in that it is a priority cost. In a similar way, payments by the Federal government through the various farm support programs are priority returns. They provide certainty in a planning process plagued with uncertainty. They are quite literally a form of guaranteed annual income.

By reducing uncertainty in farming, government support payments are of greatest value to those facing the greatest risks. The principal beneficiaries are those large farms making a heavy use of credit. The importance of these benefits increases disproportionately with size of farm and reverses the effect of a progressive income tax. This has held capital in agriculture and exercised a major influence over the pattern of size of firms.

The Role of Social and Institutional Change

Will the economic and social forces that supplied capital to American agriculture in the past be adequate for the future? Are we right to maintain income tax and farm support policies that are in effect a progressive subsidy to certain classes of investors? Is this distorting our evaluation of economies of size of firm in agriculture? It is a part of our current communal wisdom to regard the answers to these questions as dependent on technological developments. The more relevant conclusion is to recognize that social variables will be controlling.

Given the dependence of agriculture on weather, the structure of the family has been the major variable conditioning the size of farms in American agriculture. The farm in the past gave each family member something to do that was visibly productive. Each person contributed to the total welfare in a manner that could be understood and appreciated. Participation was a reality, not a slogan. Common goals existed and were comprehended. In times of crisis, identification with the farm elicited a sacrifice that made it possible to maintain the farm intact. Many family farms have been two-, three-, or four-man farms at critical seasons or for specific tasks. Returns per man-, woman-, and child-hour have been low, but the economic resiliency of the farm and its capacity to absorb shocks have been great.

Social and cultural variables are changing this life style, not just farm technology. Consolidated schools, the eight-hour day, the five-day week, coffee breaks, paid vacations, and many other dimensions of our increased leisure in urban occupations have had a pervasive influence on the farm family. As in all other sectors of American life, the hierarchical structure of the farm family is also changing. The automobile has given the farm wife much greater freedom and mobility in relative terms than its comparable impact on urban women. Rural women have realistic opportunities to enter the non-family labor force. The opportunity costs of their farm and family labor can be given a meaningful value in monetary terms. It is these changes that give the family farm a new definition. It is the family that is changing, not just the farm.

The two-man farm in this context implies a two-family farm, a connotation that is not often made explicit. Especially when livestock are involved, a multi-family farm makes it realistic to budget for labor requirements that include short work days and weeks, alternate free week-ends, and vacations. It is instructive to note that farm policy in the Netherlands, in Sweden, and in other countries of Western Europe is increasingly focused on the two-family farm as a norm [12]. Economic pressure, social norms, and cultural patterns are propelling agriculture in developed countries in this direction.

This is the setting in which it seems most rewarding to interpret the recent growth of family farm corporations. The corporate structure can give the flexibility needed to accommodate two or more families with different family goals and capacities. The impersonal nature of the corporate structure compels answers to questions about shares in ownership, value of labor and capital contributions, shares in returns, procedures for ownership transfer, and liquidation. The state, in effect, steps in as a third party and compels family members to ask and answer questions they should be considering but often avoid.

In this sense the corporation, creature and creator of the vast firms of the industrial world, may offer one of the most realistic hopes for retention and revitalization of relatively small-scale firms in the agricultural world

The challenge to our agricultural policy is to find ways to assist in the establishment of new sets of property rights and new patterns of distributive shares, to better serve a system of larger family farms and family farm corporations. By changing our institutional structure to keep pace with technological advance, we may find that the advantages we now associate with large size in farming are not the exclusive privilege of large firms.

Discussion: The Organization of Agriculture

W. D. TOUSSAINT

Professor Dovring has given us a kind of overview of tenure forms through time and across countries. From his discussion, I come away with two main thoughts. First, agriculture has tended to change when economic and technical conditions warranted the change. Technology may have been available to change production techniques substantially. Yet the changes came when factor-product price ratios were favorable for adoption of the new technology. Maybe my interpretation here is a product of my biases, but it is where I come out.

Second, Dovring seems to leave me with the idea that family farms are here to stay. At least, he points out that this form of organization has held up well when compared with alternative organizational forms. His conclusions here support those of Nikolitch [2], who certainly has gone a long way in dispelling some of the current notions that family farms are beginning to take their place with dinosaurs as relics of the past. Nikolitch doesn't suggest that family farms haven't changed drastically. They have. Yet they remain family farms in the sense of entrepreneurship and management. Some management functions formerly done on farms have moved off the farm, but who would deny that the managerial component remaining on the farm generally is more complex than ever.

Independently of Nikolitch, I had looked back at the proportions of family and hired workers among the farm labor force. I found that 75.1 percent of farm workers were family workers in 1910, and 74.4 percent

---

W. B. TOUSSAINT *is professor of economics and head of the department at North Carolina State University.*

were family workers in 1968. Also, there has been almost no change in this proportion over time. This aggregate figure glosses over too many things, but if we had had substantial shifts toward large-scale farms we should have expected a shift toward proportionately more hired labor. Professor Raup implies this also in his paper. Marshall Harris seems to take exception to these ideas in stating that "... the rights to use tenure forms and to organize production units in sizes desired by entrepreneurs seem to be leading toward large units unacceptable to advocates of family farming" [1, p. 527]. What this points out, I believe, is the extent of the confusion existing today about economies of size in agriculture and the place of the family farm in the future scheme of things.

I feel that Raup recognizes and points out quite well many of the deficiencies in our present knowledge of economies of size (and diseconomies as well) in agriculture. We would like to know how large firms can withstand extreme changes in profit, and the importance of the management input as a determining factor cannot be overemphasized. I will come back to this later. Also, I think Raup makes an important point in that social and cultural values are having their impact on farm size and farm organization. I agree that farm families (including wives) want the same amenities as nonfarm families, and this does influence farm organization. I guess it works the other way a little too, in that technology makes it easier for these amenities to be achieved.

There are points in Raup's paper (and I will concentrate on it) that concern me, however. There is a thread of reasoning running through his paper that implies that farmers have been forced to remain on farms, even though they would have been better off elsewhere. The evidence on this point is not clear to me, and I strongly suspect that the abilities of most of these small farmers were such that their best alternative was where they were, at least for some time.

Raup's analogy of the family farm and the large-scale farm both operating at full or at zero capacity bothers me on two counts. First, I guess I've never really bought that argument with respect to the family farm. Second, he argues that this would mean violent shifts in supply if large-scale farms were the rule. Yet, the conventional wisdom is that supply has been remarkably constant under our existing farm organization. I think I must be missing a link in the logic. In addition, I would expect large farms to have a large share of their costs relatively variable. What the exact shape of their marginal cost is and how it would affect production changes as prices change, I don't know.

I wish that Raup had not gone all the way from the family farm to a monopoly model in his discussion. True, monopoly could exist in specialized circumstances, but it is not a likelihood for agriculture in the near future, in my opinion. There are enough interesting problems connected with large-scale farming without bringing in the added problems of monopoly and advertising.

Labor management, as Raup notes, potentially is a serious problem of large-scale farming. It is a problem in the sense of supervision, in the sense of fitting a 40-hour week to an occupation not always adaptable to such constant hours, and in the sense of the likelihood of unionizing labor and the attendant difficulties. It would seem that the unionization of farm labor would be a substantial deterrent to the growth of large-scale farms, but more information on this point must be obtained.

Sometimes we forget that economies and diseconomies of size proceed apace as farms get bigger. I agree with Raup that the diseconomies are more difficult to measure, and I'm speaking here of diseconomies within the farm. If we are really to understand economies of size in agriculture and what they mean for future agricultural organization, we must find a way to measure these management effects. Also, we need more knowledge regarding the capabilities for growth in farmers' (or potential farmers') managerial abilities, as Raup points out.

Potential economies and diseconomies may be greatly different for different types of farms. I'm sure they must be. We need better studies that spell out these differences among farm types. I suspect, for example, that much of the land-clearing and drainage operations taking place in the Southeast could be accomplished only by rather large corporations. Yet, I believe there is a very real question whether, once cleared, these units can be more efficiently operated as one large unit or as smaller, family farms. Much must depend on management, and the differentials in managerial ability of farm operators are immense. Many have one-man or two-man limits to their managerial capabilities.

I don't know precisely where we are headed, as far as American agricultural organization is concerned. Surely, farms will be much bigger, more specialized, more mechanized, and will use more credit. Yet they may continue to be predominantly family farms—or they may not. It is quite important to get better research results relevant to this problem, a problem with substantial economic and political connotations. We need to be able to make more meaningful statements about the types of farms we can expect in the near future, as well as the potential effects of such changes on communities. One would hope that we can devise research to give us better insights into this question, and this may, in turn, bring about a more sensible evaluation of agricultural organization and its policy implications.

Discussion: The Organization of Agriculture

DANA G. DALRYMPLE

Variants and Invariants in Comparative Agricultural Systems

Dovring's paper on first reading is, I fear, a bit puzzling. Although he has much to say of value on a wide range of issues, it is sometimes difficult to follow his train of thought or to determine what his overall point is. The reasons may be twofold: His writing style tends to be baroque, and there is a failure to add up the sometimes exceptional parts into a clear theme.

To the extent that this occurs, it is unfortunate, because with a second and third reading, many valuable nuggets concerning the organization of agriculture begin to surface. Dovring has an extraordinary knowledge of the economic history of agriculture and is well abreast of contemporary problems. His writings are seldom without factual or conceptual reward.

The returns from this particular paper, however, are more apt to be intellectual than applied in nature. This is particularly true for one who, like me, is involved in international agricultural development programs. Dovring's historical analysis tends to be based heavily on Europe and the United States and is perhaps more relevant to those nations than to some of the current problems of the less developed countries.

Let me now turn to some specific comments. I should like to note both points of agreement and disagreement, but time scarcely allows both; instead, I shall follow custom and briefly question a few points.

Cooperatives

Dovring states that there is a conflict between cooperative self-help and state price-support policies. He doesn't say why, but one might infer some philosophical incompatibility. This was not wholly the case in the United States. While in the 1920's government support was metered to agriculture through cooperatives, the critical problems of the 1930's called for a more direct approach. It was decided to emphasize price supports. The "conflict" then was for limited resources.[1]

Dovring also indicates that "the fostering of cooperation would seem to be one of the main roads towards farm self-reliance and grassroots democracy" in low-income countries. I would be less sanguine, based on experience to date.

---

[1] I am indebted to Wayne Rasmussen of the Economic Research Service for this point.

DANA G. DALRYMPLE *is with the Foreign Economic Development Service, USDA.*

Socialized agriculture

Dovring seems to think that farmers' cooperatives were a contributing motive for the collectivization of agriculture in the Soviet Union. While there may have been some hope in the early 1920's that the growth or enlargement of cooperatives would lead to a communal agriculture, they were not a positive motive for collectivization. The decision to collectivize was made on quite different grounds.[2]

Dovring makes passing reference to the private plots in Soviet agriculture. I might add that from 1959 to 1965 these holdings occupied less than three percent of the arable land but accounted for about one-third of the total agricultural output. They play a particularly important role in labor-intensive crops such as fruits and vegetables [3].

Credit and subsidization

Dovring should differentiate between formal and informal credit systems. Formal credit is, I suspect, more likely to be in limited supply and used for production than is informal credit.[3] Similarly, I think it is necessary to differentiate between static and dynamic economies; when a striking new technology has been introduced in a dynamic economy, there is apt to be a greater need for credit than in a stagnant society.

Dovring states that it is "absurd for the poor countries to subsidize their agriculture." I don't think he intended to make this statement as restrictive as it sounds. Input and price-support subsidies may well be in order in the short run if they help to speed the adoption of a new technology and to get agriculture moving. As agriculture gains momentum, they may be lowered or withdrawn.

Optional society

The last two paragraphs of Dovring's paper are both provocative and puzzling. His point that the structure of American agriculture may matter little to society is an arresting one and possibly true in an overall economic sense, but it overlooks political realities. Rather than public support for "factories in the fields," the current tenor is quite in the opposite direction. In any case, the individual farmer can hardly afford to ignore economics in organizing his own business.

Many other points could be discussed. Suffice it to say that Dovring has offered much grist for further thought and argument.[4]

Economies and Diseconomies of Large-Scale Agriculture

Raup's essay provides a useful summary of recent economic studies relating to large-scale agriculture in the United States. It also offers some interesting hypotheses. The paper is, however, less international in scope than I had hoped. Since U.S. agriculture is not now my main field, I shall largely defer further comment to my fellow discussants.

---

[2] For a brief outline of the reasons as well as further references, see [1, pp. 204–206].

[3] For a discussion of the role of informal credit in one less-developed nation, see [5].

[4] Those with a further interest in systems of resource organization may wish to consult Foster [2].

But as a one-time marketing specialist, I must admit that I felt uneasy with Raup's comments on advertising and market demand. Large firms would undoubtedly attempt to increase the demand for their product, but the course they would take would be determined by a number of factors (e.g., the type of crop, degree of processing, and share of market). Direct retail advertising of the firm's own brand is only one—and perhaps not the most likely—of several possible approaches.

Like Dovring, Raup seems to neglect the unfavorable press that large corporation farms have traditionally drawn in the United States. In the future, this could be a matter of no little importance. I need only remind you of the current debate over the limitation of government payments to farmers.[5] Senator Gaylord Nelson of Wisconsin, moreover, is currently leading an investigation of the effects of corporate ownership of large farms.[6] His present attitude could not be described as favorable.

But both Raup and Nelson recognize that the incorporation of a family farm does not necessarily change its fundamental character. As one who was brought up on such a farm, I thank them for the chance to come in from the cold.

The Organization of Agriculture: An Epilogue

Gene Wunderlich

PROFESSOR Dovring has compressed an immense vision of the past and present organization of agriculture into his brief paper. As I am in general accord with him, I shall simply extend one of his points best expressed in his own words:

> The lessons of the past are not as valid for the future of the high-income countries. The basic reason is the widening range of options consequent upon rising productivity and per capital income.

We might ask, then, why are we concerned with the organization of agriculture? Is concern with the form of agriculture based on an assumed relation to efficiency, distribution, growth, or other economic feature? Or do we have an interest in form as such? If form is important either as a means or an end, do we know enough to influence or re-form agriculture in the "right" direction?

For high-income countries, at least, I think that we have been concerned too much with production, too little with distribution, and that, in our view of growth, technology has played God too long.

Any reference to the productivity of American agriculture runs the risk of being trite. Perhaps it is best summarized by an analyst of urban affairs, Lyle Fitch, who said, ". . . the agricultural development policy in large part has been a smashing success—American agriculture is the productive miracle of the world."

In the next decade or so, according to Rex Daly, output per man-hour on farms will more than double. Although this projection of present trend in productivity suggests remarkable change, the potential change is far more dramatic. If all farms produced as do the farms in the present $40,000-plus sales class, the projected production for 1980 could be supplied by one-half million farms.

Future attention to the organization of agriculture from the standpoint of farm production, therefore, might be oriented more toward the improvement of product quality, the integration with market services, and the maintenance of production flexibility. Whatever the orientation, the urgency of production problems in relation to other issues in agricultural and rural development appears to be declining.

Decisions to influence the organization of form of agriculture may well depend more upon its effect on income distribution than upon production. As Professor Raup said, the important economies and diseconomies are those that are external to the firm.

Gene Wunderlich *is with the Natural Resources Division of the Economic Research Service, USDA.*

So long as ownership of resources is vested in the persons who make the decisions on use, the relation between organization and income distribution is relatively simple. Even problems of capital accumulation and transfer are individual problems. As organization becomes more complex, the problems of incentives, rewards, and equities become matters not merely of productive efficiency but of relative well-being among participants in firms, industries, and societies.

Many features of our present property system may be growing obsolete. Private property does not always reflect interdependencies among individuals in the use of resources. As Harold Demsetz has pointed out, externalities are created when property is too ponderous to associate the interests of some people in the actions of others. The relation of property ownership to community institutions may change as residence becomes separated from property. New and increased use of rural space by an affluent, mobile population may call for the development of property interests that permit wider sharing of access.

Economists might devote less attention to production problems in agriculture and more attention to distribution problems, but I suggest we take a different view of growth problems.

The criticisms of our indexes of progress and growth by Mancur Olson, J. K. Galbraith, A. A. Berle, Jr., and others, while perhaps valid in their own right, have tended to focus on the products of the growth process. Somewhat less concern has been shown over the technocratic ideology responsible for the form and volume of goods and services.

If we assume changes in technology come upon us as exogenous, uncontrolled influences, then decision making will be directed toward adapting to new transformation functions, resource supplies or locations, or comparative locations. If farms have excess machine capacity, they must be enlarged. If desalination is successful, new areas must be irrigated. Technology occurs and then changes must take place.

James Shaffer illustrated the resignation with which agricultural economists have accepted technology when he said, "Tens of millions of people are threatened with technological displacement with little prospect of rapid and effective integration."

The assumption of omnipotent technology may be as dangerous a "fundamentalism" as the rural and urban types we have criticized. If technology is, as John McDermott says, the "opiate of the educated public" and "invested with high hopes for the improvement of mankind," its negative spillover effects can be excused in the name of progress. An advanced technological society requires agencies of highly centralized and intensive social control and a socially disciplined population. Democratic institutions are challenged. The impacts of technology on the broiler industry, for example, seem to support the McDermott viewpoint.

The attitude taken toward the management, control, formation, and distribution of the effects of technology will depend, in part, on its intended role. If acts of technological development are regarded as acts of nature, policies will be directed toward response to them. If, on the other hand, technology is regarded as an instrument of policy, perhaps it can be designed to serve other somewhat more basic ends.

The notion of controlling technology so as to encourage economic activity in the direction of other goals suggests some interesting possiblities for transforming agriculture. If we are capable, in ten years, of producing our food requirements with less than one-fourth of our present number of farms, will we need zero farmers by 1990? Or by 2000? Could food costs be reduced to the nominal level of another public service? How then to utilize agricultural resources in open areas?

In the spirit of speculation, we might consider some opportunities for a transformed American agriculture. One set of such opportunities might focus on labor and employment, another on the uses of open territory in rural areas, and still another on the uses of agriculture for cultural development.

How shall we employ our citizens? The number of persons employed in agriculture is now only a trifle higher than the unemployed of the total civilian labor force. Obviously, commercial agriculture, which had been exporting labor, will not by itself begin importing unemployed persons. Under a different set of economic conditions, perhaps in part a function of policy changes, a portion of what is now agriculture could be used as an employer of last resort, a buffer between industrial requirements and excess available labor, a retirement or supplemental occupation, a labor-intensive provider of specialized or premium quality products, and a subsistence occupation for nonconformists.

The concept of agriculture as an "employment sink" suggests an economic use of agriculture somewhere between the industrial agriculture sector and the poverty sector.

How shall we use our open space? Increasing concern on the part of Federal, state, and local governments in the management and development of rural space is part of a growing public awareness of values associated with the natural environment. If agriculture is to become a custodian of open space, it must receive instructions and incentives to offset private economic pressure to behave otherwise. Agriculture can be a type of recreation, but the commercial value of recreation as agricultural enterprise is questionable. The value of agriculture for open space is widely diffused with many features of a public good. Policies related to conservation and natural ecological balance through agriculture probably can be implemented only by large-scale private organization or government.

Can there be an "agri-culture"? If there is drama in a biological process, if there is beauty in the color and form of living things, if man can still identify with the sources of his own being, then many of the elements of an art form exist in agriculture itself. If agriculture can evoke a literature, inspire music and drama, and model paintings, perhaps it can become an art itself as did weaving, architecture, and the culinary arts, once they had transcended their vulgar purposes.

Agriculture as an art form could be casual entertainment in the form of a hobby or opportunity to satisfy drives to develop a craft or skill. Agriculture as an art form could be serious, as in life museums, for example, or as a kind of mass landscape architecture to mold vast areas.

Impossible? Unrealistic? Dovring tells us that, historically, "agriculture has been one of the most dynamic forces of human change." Why stop now when we have more means at our disposal than ever before?

ECONOMICS OF RESOURCE USE FOR DEVELOPMENT

CHAIRMAN: MAURICE KELSO, UNIVERSITY OF ARIZONA

Resource Endowments and Technological Change in Agriculture: U.S. and Japanese Experiences in International Perspective*

YUJIRO HAYAMI

THE United States and Japan, despite enormous differences in resource endowments, have attained high rates of growth in agricultural output and productivity. The patterns of growth in productivity and resource use are as contrasting as their resource endowments. This study searches for the common thread in the U.S. and Japanese agricultural growth by appraising the historical experiences of the two countries within a cross-country perspective.

Growth Records in U.S. and Japanese Agriculture

The growth records of U.S. and Japanese agriculture for 1880–1960 are summarized in Table 1. During those eighty years, agricultural output increased at the annual compound rate of 1.5 percent in the United States and 1.6 percent in Japan; output per worker increased at 2.4 percent in the United States and 1.9 percent in Japan; total factor productivity increased at 0.7 percent in the United States and 1.0 percent in Japan.

A remarkable feature is that such overall growth rates of equal magnitudes were attained under extremely different endowments of land and labor. Arable land area per male worker was less than one hectare and increased by only 60 percent during the eighty years in Japan, while in the United States it increased more than four-fold from 10 hectares in 1880 to 46 hectares in 1960. In Japan the supply of land has been inelastic and the growth in labor productivity was primarily brought about by the increase in output per unit of land area. In the United States, at least until the 1930's, labor productivity growth was primarily the result of the increase in land area per worker.

Arable land area per male worker (hectares)	10	13	18	22	46	2.0
Power per male worker (horsepower)[d]	1.8	2.2	3.0	6.7	40.9	3.9
Fertilizer per hectare (kg. in $N+K_2O_5+P_2O$)	1.5	3.3	5.0	9.5	41.6	4.1
Japan						
Output index (1880 =100)[b]	100	149	232	264	358	1.6
Productivity index						
Total productivity[c]	100	142	195	208	229	1.0
Output per male worker	100	152	238	326	453	1.9
Output per hectare of arable land	100	135	184	205	280	1.3
Factor-factor ratios (1880 =100)						
Arable land area per male worker (hectares)	0.61	0.68	0.79	0.96	0.97	0.6
Power per male worker (horsepower)[d]	0.15	0.16	0.17	0.29	1.01	2.4
Fertilizer per hectare (kg. in $N+K_2O_5+P_2O$)	13	17	63	115	260	3.8

[a] Flow variables such as output and fertilizer are five year averages centering on years shown. Stock variables such as land and labor are measured in years shown. Data sources are explained in [3].

[b] Gross output net of seeds and feed.

[c] Output divided by total input.

[d] Sum of draft animal power and tractor power.

The ways inputs other than land and labor were used and technology developed are also contrasting. In the United States it was primarily the progress of large-scale mechanization that made it possible to increase the area operated per worker. In Japan it was primarily the progress of biochemical technology, represented by seed improvements with larger application of fertilizer, that induced agricultural growth under the severe constraint of land endowment. Although U.S. agriculture has experienced significant biochemical innovations since the 1930's and farm mechanization has progressed at an accelerating pace since the 1950's in Japan, the overall contrast is conspicuous at least for the period before 1940. Is there a common thread in such contrasting histories of agricultural growth?

Cross-Country Comparison and the Hypothesis

In Figure 1a, the partial productivity ratios, agricultural output per male farm worker and output per hectare of agricultural land, are plotted for 38 countries. The slope of the line connecting each country to the origin represents the land-labor ratio or area per worker for the country.

Three distinct productivity scatters or paths can be observed: (1) the path indicated by the group of countries in the new continents, represented by New Zealand, Australia, Canada, and the United States, where man-land ratios are particularly favorable; (2) the path indicated by countries in Asia, represented by Taiwan and Japan, where unfavorable man-land ratios prevail; and (3) the path indicated by countries in Europe, represented by the Netherlands and Belgium, in which the condition of original factor endowments is between the other two groups. Each path seems to represent the long-run process of agricultural growth for a given man-land ratio. The endowments of land and labor can be treated as largely exogenous to the agricultural sector.[1] Given the resource constraints, farmers try to increase output and income. In one case, it is land that limits the increase in output; in another, it is labor. In order to ease the limitation set either by land or by labor, farmers try to economize in the use of the limiting original factor or to substitute for it with man-made inputs, e.g., fertilizer for land and tractors for labor. The growth path suggested by the countries in the new continents seems to reflect the process of easing the limitation set by labor, and the one suggested by Asian countries to reflect the process of easing the limitation set by land.

In Figure 1b, the factor-factor ratios, fertilizer input ($N + P_2O_5 + K_2O$) per hectare of the agricultural land and tractor horsepower per male worker, are plotted. The former is used as an index of the level of input of the factors that substitute for land, and the latter is an index of the input of the factors that substitute for labor. It will be seen that the productivity ratios of the respective countries in Figure 1a correspond roughly to their positions of input mix in Figure 1b.

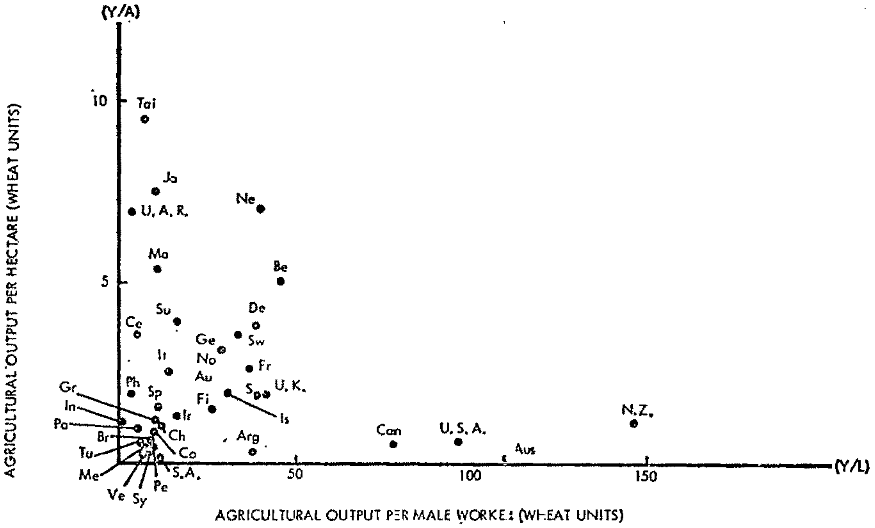
The relations observed in Figures 1a and 1b suggest the hypothesis that growth in agricultural productivity is essentially a process of adaptation of the agricultural sector to new opportunities created by the progress of inter-industry division of labor accompanying industrialization. The term industrialization, as used here, does not mean the expansion of manufacturing sector alone but rather the coordinated growth of manufacturing and service industries, including international trade and transport. If we measure the industrialization by the number of male workers in the non-agricultural sector relative to the total number of male workers, we find the countries located close to the efficiency frontier in Figure 1 are high in this ratio: 0.82 in New Zealand, 0.87 in Australia, 0.91 in the United States, 0.92 in Belgium, 0.88 in Netherlands, and 0.74 in Japan around 1960 when this comparison is made. In contrast, this ratio is very low in countries located nearby the origin: 0.41 in Mexico, 0.31 in Colombia, 0.47 in Syria, 0.39 in Turkey, and 0.31 in India and Pakistan.

---

[1] This, of course, is not exactly true. Especially, labor may better be treated as a variable determined simultaneously through as inter-industry demand and supply system. Here we treat labor as approximately exogenous to agriculture in the sense that it is primarily the nonagriculture sector which determines its share of existing labor force and that the residual is employed in agriculture sector.

Industrialization affects agriculture in many ways. The expansion of the nonagricultural sector, requiring more food and materials, shifts the demand for farm products upwards, stimulating farmers to increase the use of inputs and to adopt new technology in order to meet the increased demand. More crucial are the changes in the supply conditions of agricultural inputs. With the progress of inter-industry division of labor accompanying industrialization, increasing returns, as conceived by Allyn Young [7], set in and the costs of such modern agricultural inputs as fertilizer, chemicals, and tractors are reduced. Agricultural growth can be attained through the adaptation of the agricultural sector to the lower prices of such modern inputs relative to land, labor, and product prices.

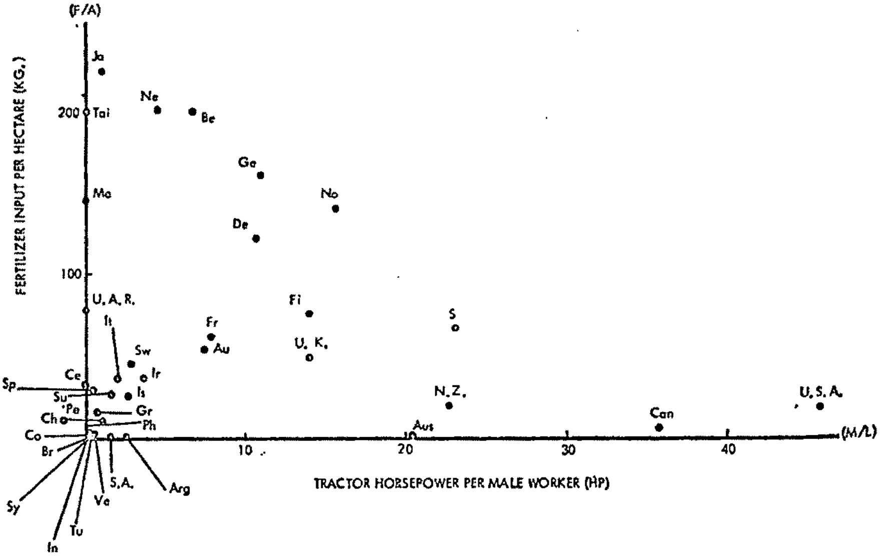
Figure 1a. Cross-country comparison of land and labor productivity ratios in agriculture



Such opportunities do not bring about productivity growth unless they are exploited adequately. A requisite for agricultural productivity growth is the capacity of the agriculture to adapt to a new set of factor and product prices. This adaptation involves not only the movement along a fixed production surface but also the creation of a new production surface that is optimum for the new set of prices.

For example, even if fertilizer prices decline relative to the prices of land and farm products, increased application of fertilizer is limited unless new crop varieties are selected which respond better to fertilizer.

Figure 1b. Cross-country comparison of fertilizer input $(N + P_2O_5 + K_2O)$ per hectare of agricultural area and tractor horsepower per male farm worker



Notes to Figures 1a and 1b: Flow variables, output, and fertilizer input are measured as 1957–62 averages. Stock variables, labor, land, and tractor horsepower are measured in years closest to 1960.

Wheat unit = equivalent to one ton of wheat; Agricultural output is aggregate of individual agricultural products using wheat relative prices as weights (one ton of wheat = 1).

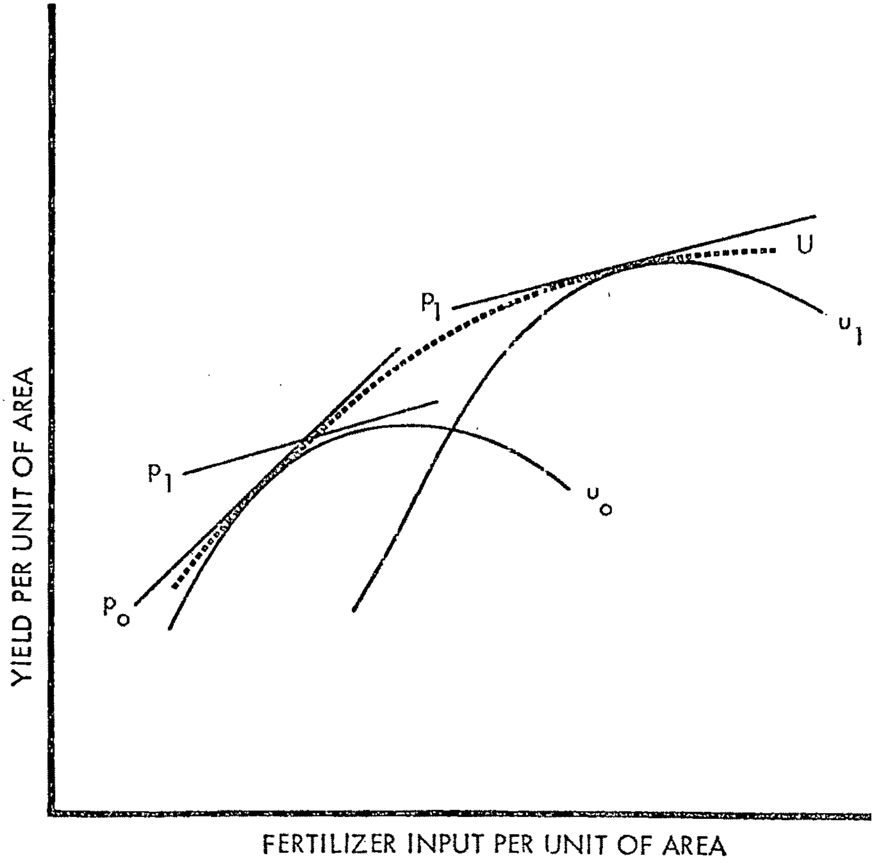
Traditional crop varieties in less developed countries have long survived under unfavorable environmental conditions with little fertilization. Consequently, they tend to have higher yields than improved varieties without fertilization but respond less to heavier fertilizer application. This relation may be drawn as u_0 and u_1 in Figure 2, which represent the fertilizer response curves of traditional and improved varieties, respectively. For farmers facing u_0, a decline in fertilizer price relative to product price (p_0 to p_1) would not create much increase in fertilizer application or in yield. The benefit of a decline in the fertilizer price can be fully exploited only when u_1 is made available to farmers through the selection of more responsive varieties.

Figure 2. Fertilizer response curves



Conceptually, it is possible to draw a curve such as U in Figure 2, which is the envelope of many such response curves, each representing a variety of different degrees of fertilizer responsiveness. The envelope may be called an "innovation frontier curve" or a "meta-production function." It is hypothesized that the adaptation of agriculture to new opportunities in the form of lower relative prices of modern inputs involves an adjustment to a new optimum along this meta-production function.[2]

The endowments of the original factors, land and labor, appear to have a significant influence upon the location of respective countries along the meta-production function. Where labor is the limiting factor—limiting in the sense that its supply is inelastic—the optimum for new opportunities in the form of lower prices of modern inputs is likely to be the point with the higher land-labor ratio. Movement to this new optimum would involve mechanical innovations embodied in the new forms of power and machinery. On the other hand, when land is the limiting factor, the new optimum is likely to be the point at which yield per hectare is higher for higher level of fertilizer input. Movement to this point would involve biochemical innovations.

It seems possible to explain the vast differences among countries in productivity and input mix in agriculture by the hypothesis of the adaptation of agriculture to the new economic opportunities created by development in the nonagricultural sector. It must be noted that this adaptation does not occur without cost. The development of a fertilizer responsive variety that is optimum for a new set of prices requires investment in research before it can actually be made available to farmers. Farmers seek new inputs and new techniques in order to move along the meta-production function in response to a new set of prices. The public research institutions and private farm supply firms perceive this demand of farmers and try to help them best exploit new opportunities. Unless this mechanism of dialectic interaction functions properly, productivity growth in agriculture is not ensured.

U.S. and Japanese Experiences in International Perspective

How do the United States and Japanese growth paths stand out in cross-country dimension? The time series paths of agricultural productivity growth in the United States and Japan are plotted in Figure 3, which presents enlargements of Figures 1a and 1b. The numbers in the parentheses indicate the percentage of male workers in nonagricultural occupations in the total number of male workers. The time-series path of the United States is nearly parallel with the line connecting Mexico, Argentina, Canada, and New Zealand, and the path of Japan is parallel with the line connecting India, the Philippines, Ceylon, and Mauritius.[3] The historical relationships between the level of industrialization and the level of agricultural productivity both in the United States and in Japan are quite similar to the cross-country relationship.

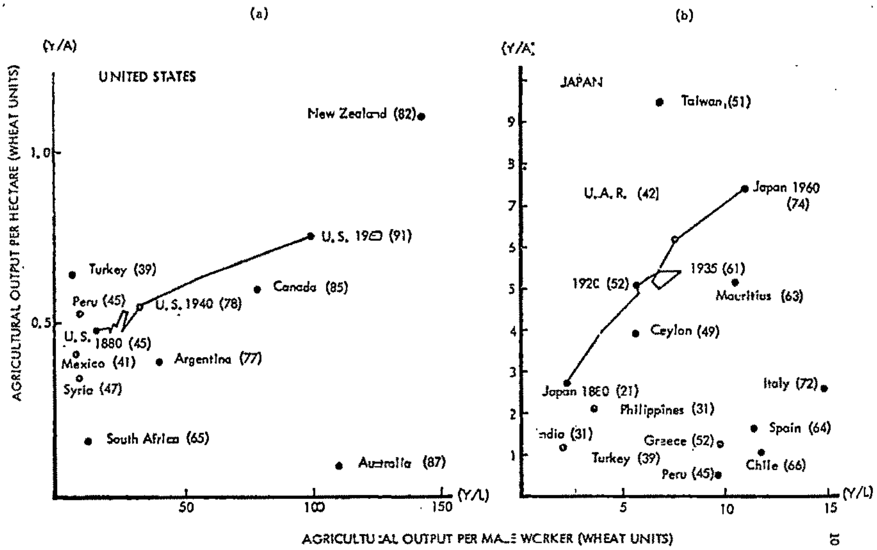
---

[2] Using a distributed lag model, Griliches explained the increase in fertilizer input solely by the relative decline in fertilizer price [1]. It could be identified that the demand schedule he estimated corresponds to this meta-production function. Unless biological innovations represented by hybrid corn occurred, fertilizer input would not have increased as much as it actually did.

[3] A line which connects India, U.A.R., and Taiwan seems to suggest the existence of another path of agricultural growth characterized by the growth in land productivity with the development of irrigation.

Considering the crudeness of data, this similarity is rather impressive. The parallel relationships between the growth path of the United States and the scatter of countries in the new continents and between the path of Japan and the scatter of Asian countries suggest that the direction of agricultural growth along the meta-production function is strongly constrained by the endowments of original factors. In Japan, land has been the limiting factor and the efforts of farmers, public institutions, and agricultural supply firms to exploit new opportunities have brought about significant biochemical innovations represented by seed improvements with larger application of fertilizer. In the United States, where labor has been more limiting, advances in mechanical technology have become the main feature of agricultural development.

Figure 3. Historical growth paths of U.S. and Japanese agriculture compared with cross-country relationship (enlargements of Figure 1a)



In the United States, the number of work animals per worker increased up to 1920, reflecting the progress of horse mechanization. Such major innovations as the introduction of the self-rake reaper as a substitute for the hand-rake reaper and the introduction of the binder as a substitute for the self-rake reaper required a larger number of horses per worker. After 1920 the number of horses per worker started to decline, but tractor horsepower per worker more than compensated for this decline. The use of the tractor was itself a major mechanical innovation in agriculture and the increase in tractor horsepower per worker represented a process of continuous mechanical innovations as it was accompanied by the improvements in transmission system, attachments, etc. The increase in power per worker accompanied dramatic decline in the price of machinery relative to the wage rate; it continuously declined from 100 in 1880 to 17 in 1960. In Japan, though the relative price of farm machinery declined, power per worker did not increase significantly, due to the strong constraint of the land-labor ratio.

In Japan, the fertilizer price relative to the price of arable land declined from 100 in 1880 to 5 in 1960. Corresponding to this rapid decline in fertilizer price, percentage in the area planted to improved varieties of rice in the total area planted in rice has increased rapidly from the beginning of the period concerned, accompanying the parallel rise in fertilizer input per hectare of arable land area (see Hayami and Yamada [5]). This clearly reflects the factor substitution along the isoquant of meta-production function. The fertilizer input per hectare increased also in the United States corresponding to the decline in the relative price of fertilizer. However, it was not until the 1930's that the U.S. level of fertilizer input per hectare reached the Japanese level of the 1880's. It is significant that the dramatic biological innovations represented by hybrid corn started at the same time. Before the 1930's, fertilizers were primarily used for cotton and tobacco, crops which are characterized by soil depletion. The depletion of natural fertility was also significant especially in the newly cultivated Great Plains. It seems likely that the level of supply of plant nutrients per unit of cropland, after deducting the depletion of natural fertility, would have remained roughly constant or even declined. This is consistent with the stagnation in land productivity before the 1930's.

As stressed previously, innovations in response to price changes in order to adjust along the meta-production function involve substantial cost. The U.S. efforts in agricultural research and extension are well known. In Japan the national efforts to develop agriculture began with the Meiji Restoration, which initiated the period of modern economic growth in Japan.[4] Beginning with the direct import of Western crops and machineries in the 1870's (which mostly turned out failures), Japan succeeded by the beginning of this century in building a rather unique system of technology called *Meiji Noho* (Meiji Agricultural Technology), which is essentially the reformulation of indigenous techniques practiced by veteran farmers on the basis of German agricultural chemistry and soil science. Farmers, especially those who belonged to the *Gono* class (landlords who cultivated part of the land they owned themselves) actively participated in the development of this technology. Most improved rice varieties available before the 1920's were the varieties selected by farmers themselves. Experiment stations made comparative yield tests and adaptive research in order to propagate the varieties selected by veteran farmers. Such techniques as the selection of rice seeds in salt water and the oblong-shaped nursery bed were selected from the farmers' practices through the tests of modern science. They were tailored by scientists and were propagated over the nation. Farm supply firms also perceived and tried to meet the demand of farmers. Long before the chemical fertilizer industry developed, the cost of plant nutrients in commercial fertilizers had declined. This was based on the efforts of fertilizer supply firms to exploit the opportunities created by the inter-industry division of labor accompanying industrialization. The costs of herring meals from Hokkaido and soybean cakes from Manchuria were greatly reduced because of improvements in transportation, storage, and marketing efficiencies.

---

[4] See, e.g., Ogura [6].

Conclusion

The agricultural growth experiences of the United States and Japan in reference to cross-country observations were explained by the hypothesis of the adaptation of the agricultural sector to the opportunities arising from the progress of the interindustry division of labor accompanying industrialization. This adaptation involves innovations produced through a dialectic interaction of farmers, public institutions, and private farm supply firms to exploit the opportunities available. The common thread in the success of U.S. and Japanese agriculture may be identified as the proper functioning of such interaction mechanism. It must be stressed that, unless there exists a system under which this mechanism works properly, industrialization would not contribute much to agricultural growth. The efforts for industrialization and economic development that neglected the establishment of such system would eventually be hampered by a lagging agriculture sector. More research must be directed to the investigation of the causes of success and failure in establishng a proper system of such interaction in the course of agricultural growth and economic development.

Natural Resources and Growth: Towards a Non-Marginal Political Economics*

A. ALLAN SCHMID

INVESTMENTS in natural resource development require a non-marginal analysis. To institute the policy changes indicated by this investment analysis also requires non-marginal changes. These are the main propositions of this paper, which is divided into a part that asks where to go and another that asks how to get there.

Land economics, as an applied branch of economics, has been marked by a concern for major changes in the use of large areas of land and water such as from rural to urban or from dry land to irrigated agriculture. It is distinguished in degree from farm management, which is concerned with changes in choice of crops and combinations of inputs. In the latter case, a partial equilibrium analysis is used to evaluate a proposed change that is small enough to produce no feedback on the many variables that are assumed constant. This is what is meant by the term marginal analysis.

Land economists have always been troubled by the inadequacy of the marginal calculus for the kinds of problems they were interested in. The changes were so large that many other variables changed. This led many investigators to search for a non-marginal economics. The search has not yet been entirely successful. Land economists have a close affinity with those specialists investigating the economics of education and technological change who are also searching for non-marginal concepts.

In marginal analysis, the problem of growth and development does not really arise explicitly. If a disequilibrium exists, it can be removed to the profit of entrepreneurs; and, as this is done the economy will grow as much as is possible. The Keynesian revolution upset this when it was understood that an equilibrium could exist at less than the productive capacity of the economy. This gave us some new handles on growth, but it concentrates on the obvious potential of unemployed labor and leaves unexplained how the quality of available inputs changes. Unemployed people or unused land is one thing, but the skill level of the labor force and the quality of the land are another matter. The untapped potential of these is less obvious. Still, historical study suggests that there are opportu-

A. ALLAN SCHMID *was with the Systems Analysis Group (Civil Works) of the Office of the Secretary of the Army, on leave from Michigan State University.*

nities for man to change the resources base. However, its change has remained largely outside of economic theory and investments to that end have proceeded, in too many instances, by blind faith.

Investment is of course subject to analysis. But investment in quality and new kinds of inputs is a distinctly non-marginal phenomenon. A change in skill level or bringing water to new land produces feedback and ramifications difficult to contain in marginal analysis. Also, the returns to this type of investment are difficult for private enterpreneurs to capture. The concepts of externality and "public goods" have been explored elsewhere [14]. It is enough to note here the important role of governmental investment in changing the resource base, whether it be man or nature.

This paper will explore illustrations of natural resource investments where marginal analysis is of limited usefulness. It further inquires into what can be done to introduce non-marginal changes in policy and institutions. The examples will deal with water resources, but many of the same points could be made with regard to other resources.

Part I: Where to Go

Resource investments versus other expenditures

The first substantive issue I want to explore is comparing the returns to public investments in natural resources versus other kinds of expenditures. One line of inquiry that must be examined is what might be called the RFF school of thought. It is argued by such Resources For The Future, Inc. associated writers as Harold Barnett that resource scarcity and rising resource prices are unlikely because of technological change [2]. The implication is that neither conservation nor investment directly associated with resources is as important as investment in new technology. Yet the latter remains largely undefined, and it is not clear how this technological advance can be maintained. How much of the past productivity increases in agriculture, for example, came from irrigation, drainage, and flood control as opposed to things like hybrid seeds and smarter farmers? Some studies of national growth assume a constant input of land. Yet the acres used today are not of the same quality as those of 50 years ago. I suspect we have grossly underestimated the impact of flood protection, which has probably added more productive acres than irrigation. However, it is symptomatic of our lack of consideration of explicit tradeoffs among alternative investments which improve the quality of inputs that there is no systematic record of the acreage involved, let alone the amount of production involved.

I do not mean to suggest that I think there are further great opportunities in developing new lands. However, I would like to see the historical record cleared up before we advise other nations to forget about natural resources investment since they played such a minor role in U. S. agricultural growth. There is one other international aspect that deserves note in passing. What happens if the whole world population consumed natural resources at the U.S. rate? Would technology still keep up?

Charles Howe has inventoried the available studies of the marginal returns to irrigation water and compared these with the costs of major new development from inter-basin transfer [6]. He concludes that these are marginal investments. Vernon Ruttan also concludes that irrigation returns do not seem to cover costs [11, p. 49]. Yet one can agree with this and still note, as Ruttan does, that some areas remain where there are good projects. The problem seems to be that our Federal or state agencies cannot always separate the remaining good ones from the poor ones.

Studies of education and research have compared returns there to such things as irrigation projects. Zvi Griliches shows returns to hybrid corn of hundreds of percent and contrasts this to low benefit-cost ratios for Federal irrigation projects [5]. While I share the thrust of his conclusion, I have some reservations. The problem turns on the non-marginal impact of both kinds of investment. Hybrid corn has increased production enough to affect prices. Griliches counts the consumer surplus in the hybrid research returns. However, he makes comparison with individual project studies for irrigation where there is no effect on price. Yet, if one is to draw conclusions on program priorities, the irrigation projects would have to be considered all together and the consumer surplus calculated for them as well. Griliches also ignores change in the quality of land used for corn. Again drawing conclusions for other countries I hope it will be remembered that even with hybrid corn and educated farmers, crops are poor on eroded, dust bowl land. There are some real problems in calculating contributions to real income gain over time that remain unsolved.

Urban development

On the urban development side, the case for water supply development is mixed. Charles Howe, in investigating the relationship of regional growth and different measures of water availability, concluded that "the evidence of the 1950–1960 decade . . . demonstrates that water did not constitute a bottleneck to rapid economic growth in water deficit areas of this country, nor did its presence in large quantities in other regions guarantee rapid growth of these regions" [7]. Robert Young makes a similar argument from his studies in Arizona and concludes that "the evidence demonstrates that water has not been the limiting factor on growth in Arizona up to the present time" [20].

On the other hand, it is clear that there are some areas where water supply is a real problem. The state of California has embarked on a multimillion dollar project to bring more water to southern California. While they might have had the alternative of reallocating irrigation water, this opportunity does not exist for New York or Washington, D.C., which narrowly missed a severe curtailment in use in the summer of 1969, saved only by last minute rains. There appear to be opportunities to develop regional metropolitan water systems, which should be further investigated.

Water as a resource for waste disposal also seems in great demand. A proposed Philadelphia housing development was prohibited in 1969 because the quality of the Delaware River was threatened [3]. This has happened in numerous other cities and probably would affect more if pollution control agencies enforced their regulations. While I judge that returns are high in water quality investments, I also fear that a great deal of money will be wasted on some very marginal improvements. This country seems to have an extensive resource development bias. We seem to do more for isolated national parks than for metropolitan parks and water fronts. We may be about to see some tired old water projects given new benefits by claiming water quality improvements even though these are marginal and in areas of low priority for that purpose. For another example, water agencies tend to use the same value for a recreation day in a sparse area as for one in a densely populated area.

Prest and Turvey in their authoritative review article on benefit-cost analysis note that present methods are not useful for analyzing returns from widely different kinds of programs [10]. The reasons for this include some of the non-marginal problems already mentioned. In addition, it is related to the fact that many of the goods produced have no market prices and must be priced by governmental representatives. I believe that, increasingly, the high valued water use will be for direct consumption, such as is involved in recreation, rather than as a producer good. We can never make any sense out of these investments until the publicly generated prices for these goods are made clear. Legislators are loathe to do this and try to shift the problem of representing their constituents to agency technicians. They hope the technicians will give them a "scientific" price, which in turn can be used to convince consumers that the reported price is in fact what they are willing to pay. Consumers are just becoming sensitive to many environmental products and, as for any new product, demand is uncertain.

There is another kind of problem in comparing resource development investments that does not arise in farm management analysis. In any area where public action is prominent, the Government has two broad ways to affect resource use: the investment route and the direct controls route [13]. Controls including zoning and other modifications of property rights. These are sometimes complements and sometimes substitutes for public spending. The move toward a non-marginal analysis must accommodate these dimensions.

To conclude this section, it can noted that, although the analytics are weak, there appears to be a need for some rather large changes in agency functions and allocation of budgets and water use. These are all going to come harder than the decision to shift cropping patterns a bit from corn to soybeans in response to a marginal change in prices.

Investment complementarity

One of the potential productivity gains in an economy is to take full advantage of economies of scale. To do so requires that different industries that use each other's inputs develop together, so that the one's expansion is not hampered by high cost inputs from the other which doesn't expand to optimum size because of an inadequate volume of demand for its product. Various Federal agencies are searching for the key input to trigger development. The water agencies think it is water while other agencies plead for highways, hospitals, schools, or what have you. My hypothesis is that there is no one key, but that several of these along with private investment must be brought off together.

In many respects private industry has done better at organizing different activities simultaneously than government, which is avowed to have the advantage in such matters. A prime example is vertical integration in broiler production where feed milling, feeding, and broiler processing are closely linked by advance contracts. In most public resource investments, by contrast, the factor improvement is made, and it is hoped that other investment will follow based on the disequilibria created. However, these are frequently not large enough to get movement in severely depressed areas. Industry often helps confuse the issue by assuring project planners that they will come in if only new water, navigation, or flood-free land is provided. Since such assurances have no cost to industry, it is a convenient way to increase the number of available sites and perhaps beat down land prices a bit.

Each agency applying analysis to its own marginal project is not going to be good enough. The federal water agencies are now in the process of revising evaluation practices to reflect indirect development impacts [18]. The weak link in such evaluation is to be sure that the water investment actually will create new jobs for unemployed. After this is established, the multiplier effects are relatively easy to compute. The proposed new evaluation practices are largely silent on how to capture economies of scale necessary to get the first round of employment effects. I suspect this is due more to failure to solve the institutional problem of coordination than to the analytic problem of calculating the benefits of such coordination. Here, the institutional economics lags behind the production economics opportunities.

This is a field where foreign economic development experience and domestic experience can aid each other. In some respects the foreign literature, such as that of Hirschman and Chenery, is far ahead of that developed on U.S. regional problems.

Public water investment and land value appreciation

Whatever the accomplishments of flood control programs, and they are many, there is one blemish on the record that dramatizes the failure to take a non-marginal systems view of resource problems. In spite of spending over $7 billion since 1936 in public investment in flood control structures, the annual damage is greater than before [1]. This is because each investment was conceived individually and ignored subsequent development of the flood plain.

The current practice is to count as a flood plain protection benefit the value of the land before and after the project. This ignores alternative sites for development. The correct benefit concept, which is well understood (but not used) by the agencies, is the difference in rents between the protected flood plain site and other sites that would be built on if the flood plain were not protected. In other words, the benefit is the net locational advantage of the protected flood plain, not the total appreciation in its value. The theory is clear, but the practice is weak.

I think it is the economists' responsibility not only to formulate good economic concepts but also to inquire why demand for their use is so small. It is my observation that poor project analysis won't be corrected until the political pressure groups concerned with the project see their interests differently. At present, in the preparation of a project report, the flood plain owners are sensitized as to the potential benefits to them. This becomes a political force as these people pressure their public representatives for the project. No one sensitizes the nearby upland owner to the fact that his land would have increased greatly in value if the predicted growth for the area materializes and the flood plain were not protected. The upland owner is thus not a political force and the economist stands alone as the abstract defender of the unknowing public interest. Somehow, the other interests must be informed and formed into effective political action, or the economic concepts will remain in the textbook rather than in government evaluation manuals. I believe there is an important role for extension education here which I will discuss more below.

The problem of owners striving to capture land appreciation from public improvements is not confined to flood control projects. This phenomenon distorts the planning for urban renewal, navigation projects, parks, highways, and urban land use [12]. I don't believe this pressure can be entirely neutralized by mobilizing owners of alternative sites. A fundamental reform in our concepts of who owns these appreciation values is in order. I believe that the public must capture some of this gain to prevent distortion of public land use planning and investment.

Part II: How to Get There

Organizing for non-marginal change

Once I would have said that the key to better public investments was to improve evaluation practices. Now, I believe that other things must be changed first. Already discussed is the role of educating new groups of affected people to change the present mix of political pressures. I believe this is the basic step, but others are also needed.

One of the basic problems is to present information and have it acted on in such a way as to facilitate consideration of alternative public programs. Former Budget Bureau Director Charles Schultze notes, "There is no mechanism by which Congressman and communities can forego pressing for a marginal public works project in return for a vocational education project . . . which may have a much higher payoff to the community" [15]. He argues that it is difficult to get programs which are geographically selective. To get a program passed requires something for nearly everyone even if the program has low priority for some. This encourages each community to get what it can from each program, even though it might prefer to give up some to get more of others.

I believe the answer to this problem is to have agencies make budget allocations first on a regional basis. Many Federal agencies have field offices that produce much of the information needed for program formulation. If a region were allocated a given budget amount for a five-year period, it would encourage explicit project tradeoffs within the region. There is always a tendency for a field office to recommend the currently available project and ignore better ones that are coming in the near future. But if they had a five-year regional allocation and a marginal project were available in the first year, the field office and its local constituency would be encouraged to recommend bypassing it for more wanted projects available in later years that are still within the regional budget constraints.

This system does not in itself make it possible to make tradeoffs between one agency program and that of others. However, within the regional allocation for the five-year period, the region is encouraged to consider water projects that are functionally selective as to geography and time. If all agency budgets were made in a similar fashion, it might facilitate functional trade-offs of a broad character. Groups of Congressmen could then see the budget going to their region and could ask themselves if the mix of programs is best for them instead of seeing the game as getting their share of every program each year, even if it has relatively low priority in the region.

All of this will appear nonsensical to the analytic purist. If Congress could rely on evaluation procedures to produce meaningful benefit-cost ratios, it could just go down the list after deciding on the budget level. But, alas, as I have already noted, this world is not that way. And I don't believe the evaluation procedures will get better until some of the other rules of the game are changed.

This will require a non-marginal change and will be difficult to institute. I observe that the PPBS activity and multi-year planning in the Federal government is not widely used. Still, there are hopeful signs. If one looks backward, there have been some attempts to organize decisions to facilitate regional tradeoffs. In 1950, the President's Water Resources Policy Commission recommended a Board of Review that "would propose allocations of the total investment, basin by basin, to the construction agencies . . ." [9, p. 90]. In 1955, the House Public Works Committee was organized for a time on regional rather than agency lines, and the budgets for the Corps of Engineers and Bureau of Reclamation were considered together by the same regional subcommittee. Looking at the present and future, the Department of Army has utilized budget allocations to regions in its civil works program [16, 17]. On May 21, 1969, President Nixon established coterminous field administrative regions for the Department of Labor, HEW, OEO, HUD, and SBA [8].

Irrational drive for rationality?

Economists have a learned, if not congenital, bias in favor of explicit decision making. We like to see objectives clearly laid out and alternative programs noted and a sharp choice made. Many government bureaucrats and other politicians seem to prefer obfuscation. Decisions seem to ooze out of the system. Surely in the end there are tradeoffs, but they are seldom clearly perceived as such. This difference does not make economists greatly loved in Washington or other halls of government. Instead of simply feeling superior, I feel we must inquire deeply into the preferences about explicit rationality.

Decisions are made by people and interpersonal relationships are important in and of themselves. One advantage of obfuscation and vaguely defined decision is that it is harder to tell who won and who lost. It is personally advantageous to some participants if it appears that everyone wins, even if in fact this is not the case. *Explicitness heightens conflict.* And as the political scientist, Aaron Wildavsky, keeps reminding economists, conflict is a cost and a performance factor to be considered in evaluating the output of a system [19]. Maybe economists have a higher tolerance for conflict than bureaucrats; or our stance may be the result of advising from afar, where the costs of conflict and defeat are never directly felt.

While I acknowledge the validity of Wildavsky's point, I think it can be carried too far. Conflict is a fact of life unless people all have similar tastes and there is no scarcity. The fact that two mutually exclusive acts cannot be pursued simultaneously can be covered by confusion and ignorance, but the consequences will remain even if they can't be causally identified. I perceive a lot of frustrated people in the United States who believe that all is not right but who can't identify the cause of their discontent. Oh yes, there are those who claim it is all caused by too much permissiveness, the availability of sex education, or a liberal Supreme Court. But this type of nonsense is what you would expect if the real conflicts and choices are not clearly perceived. The cost of concealed conflict over real tradeoffs and alternatives is a public that flails out in all directions and is unaware of the cause of their troubles. While the warning that explicit tradeoffs may raise conflict levels is worth noting, I am not sure that a public which is not clear on causes of discontent will avoid fights. Fights over vaguely perceived issues may be less productive than other kinds.

Conclusion: toward a client-centered political economy

The day of the lone academic scribbler who affects practical affairs by the sheer weight of his professional publication is over, if indeed it ever existed. I do not believe that research results can just be thrown on the market to be used by a undetermined consumer at an undetermined time. Demand must be cultivated, as for any product. The same can be said for extension education. The time to do research and extend it is in the context of particular problems. For example, further general studies of alternatives to flood plain protection are next to worthless. The government agency who one might hope would use them will be powerless to do so, as I have already noted. It will be most effective if it can be used to sensitize some of the potential interest groups not now comprising effective political forces. If these groups can be brought to life, there will be some chance to revise agency evaluation practices.

I believe that research and extension must be done more in a team context, with producers and users closely anticipating each other. I shall call this a client-centered political economics. This group effort at times must include not only academic and government researchers, but also congressional staffs, local planning officials, and private groups. The immediate cry will be that the researcher will lose his objectivity if he becomes involved in anything more than dumping his new information on the market. I am aware of this danger, but also impressed by the other danger of irrelevancy.

In conclusion, I am not optimistic that we can either develop a non-marginal analysis to look at large changes in the resource base through public investment or create new institutions to achieve non-marginal policy changes. A friend of mine defines a non-marginal change as one that never happens. He may be right. Analysts often base their policy advice on what they think an aroused public might want if it were as well informed as the analyst. But the fact is that the public is seldom aroused and informed. It is disheartening to see a Gallup poll made a few days before the crucial Senate vote on the deployment of the anti-ballistic missile that estimated 58 percent of Americans were either unaware of the program or had not made up their minds about it [4]. If people won't become informed or make up their minds on this kind of issue, with its wide publicity, what chance do I have to get them interested or informed on the evaluation of flood plain benefits or the even more abstract question of the role of resources in economic growth?

Natural Resources in Economic Growth: The Role of Institutions and Policies*

S. V. CIRIACY-WANTRUP

Focus of this Paper

DURING the last ten years, it has become the fashion among economists to emphasize the decreasing importance of natural resources in economic growth. This applies especially to the renewable resources used by agriculture [21, 23]. Use of these resources is strongly influenced by economic institutions, both in developed and undeveloped economies. It is not surprising, therefore, that there has been, in recent literature, a de-emphasis of the role of institutions paralleling that of natural resources. In the current mathematical models of economic growth, the role of institutions is not explicitly considered [11, 14, 10]. In a well-known book on transforming traditional agriculture [24], the author devotes the only two pages on the influence of economic institutions to land tenancy.[1]

Emphasis has shifted from natural resources and economic institutions to technological change or, in production function terminology, to "new" or "modern" factors of production. If institutions are considered at all, they are treated as factors furnishing services like other factors of production. Changes in the kind and quantity of institutional services are regarded as determined by an economic demand-supply scheme [22].

In accordance with my assignment, I should like to focus on this doctrine of the decreasing importance of natural resources and the relatively insignificant and passive role of institutions in economic growth. I should like to analyze its validity, inquire into its relevancy, and show its implications for policy in developing countries.

Decreasing Importance of Natural Resources in Economic Growth?

The doctrine of the decreasing importance of natural resources in economic growth is based on the observation, documented largely for the United States, that the shares of agriculture and of agricultural land in

---

* Giannini Foundation Research Paper 294.

[1] According to Schultz, this influence operates solely through profitability of tenant farming. Profitability is regarded throughout as a "strong explanatory variable" [24, pp. 167 and 168]. Edmundo Flores' emphasis on land reform as the basic issue in increasing Mexico's agricultural productivity is explicitly rejected [24, p. 19].

S. V. CIRIACY-WANTRUP *is professor of agricultural economics and agricultural economist in the Experiment Station and on the Giannini Foundation, University of California, Berkeley.*

the national income have decreased in the course of economic growth. Two questions arise with respect to this observation.

First, does the fact that the income shares of agriculture and agricultural land have decreased in the United States since the last quarter of the nineteenth century mean that the income shares of all natural resources used by agriculture, including those used also by the rest of the economy, have decreased? Further, can the experience with the agricultural sector in the United States during a particular period of economic history be extrapolated to other sectors, other time periods, and other national economies?

Second, even if the first question can be answered in the affirmative, what is the meaning of a decreasing income share in terms of the "importance" of natural resources in economic growth? What are the implications for explaining, projecting, and influencing economic growth?

Let us turn to the first question. The natural resources used by agriculture are mainly land, water, and climate. All three are used also by industry, transportation, urban settlements, and recreation. For this reason, referring to differences in demand elasticities for the products of agriculture on the one side and those of the industrial, transportation, urban, and recreational sectors on the other and then equating agriculture with natural resources are not permissible.

Shifts of these natural resources out of agriculture into other uses proceed at different rates and with different geographical impact. In California, for example, the shifts of agricultural land and water into industrial, transportation, urban, and recreational uses is a relatively recent phenomenon but has progressed further than in other parts of the country [7]. This shift involves price increases for natural resources that are frequently a multiple of prices prevailing in agriculture. Admittedly, the quantities of land and water used in agriculture are still large compared with those used in other sectors.[2] But this relationship is changing in favor of nonagricultural uses.

Next, we may note that the decrease in the income share of agriculture in the United States took place in a period of history when the terms of trade moved against agriculture internationally for a number of specific historical reasons which are not likely to recur in the same combination. Terms of trade were affected by the expansion of agriculture into less-developed regions, the mechanization and intensification of agriculture in more developed regions, and, cyclically, by economic fluctuations—especially during the 50-year "cycle" connected with the name of Kondratieff

---

[2] Because of these weights, the study by Goldsmith, Brady, and Mendershausen [12] shows a decreasing share of *all* land in the wealth of the United States, but this study applies only to the period 1896–1956 and is subject to a number of statistical difficulties with respect to comprehensiveness and valuation.

[3]. Cyclical effects are distorting when income shares of sectors and factors are compared for periods, such as census years, falling into different phases of economic fluctuations.

With respect to climate and the increasingly important group of amenity resources—such as scenic attractions, public parks, clean water and air, and wilderness areas—it is difficult or impossible to evaluate shares in national income and wealth because the market system furnishes prices only incompletely or not at all. Still, there is little doubt that the significance of these resources for the location of industry and nonagricultural residence—including second homes—and for the income shares going to transportation, communication, and other services has greatly increased in the United States during the same period for which a decrease in the importance of natural resources is being claimed. There is also little doubt that the price society must pay for safeguarding the quality of these resources is increasing greatly and will continue to do so in the future.

With respect to natural resources originating and mainly used outside of agriculture, such as minerals and energy resources, there is evidence that their income shares have increased in the United States in some periods and decreased in others [19]. Here, also, the effect of economic fluctuations is significant.

In summary, then, we should be cautious in extrapolating an observation that applies to agriculture and agricultural land in the United States during a particular period of its economic history to all natural resources, time periods, and economies. On the basis of the available evidence, the validity of such extrapolation appears at least questionable. The possibilities for such extrapolation depend on the type of natural resource considered, on the type of technological change that interacts with the resource, on factors affecting the terms of trade of the products of the resource, and, last but not least, on the degree to which the resource is integrated into the market system.

Let us now turn to our second question and disregard for a moment the cautionary remarks just made. What does the alleged decreasing "importance" of natural resources in economic growth mean for explaining and projecting economic growth and for public policy aimed at generating and influencing economic growth? The reply, I am afraid, must be that it is irrelevant.

A decreasing income share may be due to greater efficiencies in a sector favored by technological change, making its product cheaper—especially if demand elasticities are low—and/or releasing factors for other employment. Are we to argue that such a sector or the services employed in it have become less important for economic growth? The opposite would seem more plausible.

A decreasing income share of a sector, on the other hand, may be due to the growth of other sectors producing substitutes for particular uses. Historically, this has been the case in many minerals and energy resources (charcoal, bituminous coal, sperm oil, etc.). Still, this does not indicate that the individual natural resources replaced in particular uses and the larger groups of the natural resources to which they belong have become less important in economic growth.

The whole question of the importance or unimportance of natural resources in economic growth to which so much attention has been devoted in the last ten years, generously financed by some research foundations, appears rather banal. In the relation that one may call the resources function, all relevant variables are important [5, Ch. 3]. Nobody has yet claimed that natural resources are irrelevant in economic growth. In the continuously changing interplay of challenge and response between natural environment and human culture, it is meaningless to say that the challenge is less important than the response. Both are a part of the same system—that of human ecology. If there were no challenge, there would be no response. And, I may add, challenges may yet appear that will prove overwhelming to the response.

The Role of Economic Institutions in Economic Growth: Factors or Decision Systems?

The remainder of my allotted time will be devoted to a more meaningful subject—the role of economic institutions in economic growth. In this connection, the mathematical models of economic growth need not be considered because, as stated above, economic institutions are not a part of their input. The output from a mathematical-statistical formulation depends on its input. If one is interested in explaining economic growth as a historical phenomenon and in development policy in the political reality of today, such models have little to offer. Good critiques by economists concerned with development policy are already available.[3] Rather, I should like to focus on the treatment of economic institutions in the book on traditional agriculture mentioned earlier.

To avoid misunderstanding, the main theses of the book are not under discussion. Within the assumptions and terminology employed, traditional agriculture can be regarded as efficient; and its marginal productivity of labor is greater than zero. Neither is it my main criticism that technological change is segmented into "new" factors in order to speak of "shifts" of a global production function—although understanding is scarcely advanced by such terminology.[4] Historically, technological change has pro-

---

[3] See the discussion of the Ranis and Fei and Jorgenson models by John W. Mellor [17]. Also, see the discussion of institutional influences by John M. Brewster [2].

[4] Since multidimensional relations are involved, one must, strictly, speak of movements to production hypersurfaces.

ceeded through packages of interrelated changes of many factors. The nature of these interrelations over time, the *Gestalt* of technological change, if you like, is the phenomenon that needs understanding rather than the appearance as a *deus ex machina* of quantities of "new" individual factors. I mention this merely because institutions are subjected to the same segmentation as technological change. My main criticism is that the book presents a conceptually insufficient model of economic growth because the role of institutions is left out.

Sometimes the author himself seems vaguely aware of this insufficiency. He is "puzzled" by economic decisions under a feudal land-tenure system and "baffled" by the economic behavior of plantation owners under a system of slavery.[5] Still, none of the economic institutions that are significant for resource use—such as the systems of owning and using property, the systems of water rights, taxation, collective and cooperative organizations, and quasi-governmental agencies like public districts—is mentioned, much less systematically treated. Economic growth proceeds in an institutional vacuum as far as natural resources are concerned.

Is this vacuum filled by the belated admission of institutions as factors [22, p. 1117], the services of which are supplied in kind and quantity in accordance with the demand for them until a demand-supply equilibrium is reached?[6] This comforting notion is presented as a "theory" in a field in which it is claimed that "there are virtually no terms of reference, concepts with specifications that can be identified and no economic theory to guide the analysis" [22, p. 1114]. The facts are quite to the contrary. Institutions have been the central focus of the study of social organization for more than a century, both by adherents of the theory of economic determinism of institutions and by its opponents.

While Marx, Engels, and Kautsky emphasized the role of technological change in economic growth and the economic determinism of institutions, they, as well as non-Marxian adherents of economic determinism, were too aware of the relations between economics and social organization to press institutions into a simplistic demand-supply scheme.[7] They recognized that the demand for changes of institutions is always opposed by demand for the status quo or demand for change in the opposite direction. They recognized also that a new equilibrium between conflicting demands on the one side and institutional change on the other is a long and hard struggle and is brought to conclusion by political rather than economic forces and tools.

---

[5] "Why many of the farmers who own and are responsible for the operation of very large farms, especially in some parts of South America, do not successfully engage in the search for modern agricultural factors is a puzzle" [24, p. 174]. "Why better health and longer life were not realized [for slaves in the antebellum South] is baffling" [24, p. 180].

[6] The author must be aware that the economic definitions of demand, supply, and equilibrium do not apply in the cases he discusses. Clarity is not served by interchanging the more general sense of a word with its precise scientific connotation.

[7] Compared with Marx and Engels, Kautsky has not gained a wide reputation in this country. He was, however, an economic theorist of some stature, who was especially interested in the role of agriculture in economic growth [15, 16]. Besides Marx, Engels, and Kautsky, a long list of non-Marxian works could be mentioned. The best known in the United States is probably Charles A. Beard [1].

The position of scholars who do not accept the theory of economic determinism of institutions—like Emile Durkheim in France; Max Weber, Werner Sombart, and Eduard Hahn in Germany; and W. I. Thomas and Talcott Parsons in the United States—is not affected by this recent oversimplified version of economic determinism [10, 13, 18, 25, 26, 27, 28].

What, then, is the essence of economic institutions? We may conceptualize an institution as a social decision system that provides decision rules for adjusting and accommodating, over time, *conflicting* demands (using the word in its more general sense) from different interest groups in a society. A change in the demand from one interest group, therefore, rarely effects a change in institutions. A feudal land-tenure system does not change merely because serfs or tenants demand it. A water-rights system based on the riparian doctrine does not change simply because nonriparians demand it. A system of taxation does not change because one or even the majority of taxpayers demand it. It all depends on the effectiveness of different demands, that is, on the relative weight of the interest groups from which demands originate. The locus where conflicting demands meet and where the relative weight of interest groups is determined is the political arena rather than the marketplace. For this reason, changes in economic institutions are usually slow and often require political changes and sometimes outright revolution. Changes in the feudal land-tenure system in Europe took centuries. In South America the change of similar land-tenure systems is still in progress. A hundred years after abolition, the economic effects of slavery in the United States are still present. It took half a century and required a constitutional amendment for the appropriation doctrine to obtain co-equal status with the riparian doctrine in the water-rights system of California· Tax reform in the United States is talked about for decades; but as every newspaper reader knows, accomplishments are slow.

Demands for institutional change may not even originate from those groups directly involved, such as the landlords and tenants in tenure systems. The demand may come from other groups because of what one might call the externalities of land tenure—that is, the benefits and costs incident on social groups other than landlords and tenants. This is frequently true for the collectivization of agriculture in order to promote industrial growth and the stability of a socialist political system. Other examples are tenure changes in fugitive resources—such as fisheries, range, oil, and gas—to further the social objectives of conservation. We are presently studying a case of this kind for a nomadic group of tribes in East Africa—the Masai. Here, tenure changes are demanded by the government in order to conserve the range resource and the game herds sharing use of the resource with the Masai livestock. The game herds, in turn, are important for economic growth as the basis for a flourishing tourist trade and large foreign-exchange earnings. If the demand for institutional change originates outside the groups directly involved, the changes required are even more clearly political and sociological and usually involve various degrees of "persuasion."

Economic institutions conceptualized as social decision systems provide decision rules both for the use of resources and for the distribution of the income stream derived from such use. This distribution has strong effects on the demand for institutional change. But such income effects are frequently just the opposite of those claimed by the doctrine under discussion. In other words, the demand for institutional change is increased if the income stream of a social group is decreased absolutely or relatively. The demand for changes in the feudal system in Central Europe was increased through dispossession of the peasants in the course of enclosures, and the demand for labor legislation in England was sparked by the misery of the working class during the first stages of the industrial revolution.

Our conceptual framework is not complete by designating economic institutions as social decision systems. I have tried to show elsewhere that economic institutions operate on the second level of a three-level hierarchy of decision systems [9]. Understanding of the relations between the three levels is necessary for devising public policies. On each level, the structure, the functioning, and the performance of the decision system can be studied both conceptually and observationally. For economic institutions affecting private conservation decisions, that is, decisions on the first level, such a study has long proved its usefulness [5]. Water institutions likewise have been analyzed within this framework [4, 8].

To bring this framework closer to the realities of development policy, I should like to illustrate it by some observations regarding the role of water institutions in northern India under the impact of the green revolution—the rapid spread of a new cereal technology based on varieties with greater capacity to combine with complementary inputs, such as labor, fertilizer, and especially water. Because of time limits and because our study is not completed, I can only sketch the main issues.

The Role of Water Institutions in Northern India Under the Impact of the Green Revolution

The results of the green revolution, expressed in yields per acre, increase in acreage of high yielding varieties, and total production, need not be recounted here. This revolution has spread so rapidly in northern India, Mexico, and several other countries because it requires the least institutional change of any new technology that I know of—at least in the initial stages. In subsequent stages, however, institutional changes will become necessary. Of these, changes in water institutions will be the most essential and the most difficult to bring about.

My concern is that the doctrine discussed in the preceding sections will lead to complacency regarding the institutional difficulties that lie ahead in realizing the full benefits of the green revolution and avoiding serious setbacks. According to this doctrine, there are no such difficulties because farmers themselves will accomplish those changes of water institutions that become necessary.[8] Let us take a closer look at this projection.

In northern India, irrigation has been based for centuries on groundwater lifted from open wells by the Persian wheel, a simple but ingenious device to develop groundwater resources where they are available in large quantities not more than some 40 feet below the surface. This is the situation in large parts of the extensive Indo-Gangetic Plain.

Groundwater use is usually possible on a more individualistic basis than surface water use. This is especially true for the relatively small, low-capacity development of groundwater based on the Persian wheel. The farmer can build, maintain, and operate the water facility himself or with the help of a small number of villagers. Water is available to the individual farmer where he wants it, when he wants it, and in quantities and over time periods that are under his own control.

An irrigation economy dominated by the Persian wheel differs greatly from one that is based on diversion from large rivers, such as in ancient Egypt and Mesopotamia, or, in modern times, from large multipurpose reservoirs. Here, the individual farmer is dependent on other farmers for building, maintaining, and operating the diversion facilities and the canal system that distributes the water. He must take his water at certain points on the canal. He must take his turn as to when the water is available to him. Quantities of water are rationed to him, and these rations may vary over time for reasons outside his own control. What is the effect of these fundamental differences in the irrigation economy on the development of water institutions?

In a diversion economy, water institutions—such as water rights, water districts, a water master, and public agencies engaged in building, maintaining, and operating facilities—are a necessary condition from the beginning. In a water economy based on the Persian wheel, such institutions are not needed and do not develop. Groundwater institutions become a necessity only when water use by one farmer affects his neighbor. This happens when the Persian wheel is replaced by modern deep-well pumps. Here the neighbor is affected by the pumping cone and by the seasonal and often secular depletion of the resource because of high-capacity pumps.

---

[8] As Professor Schultz puts it, farmers "will join with neighbors to acquire tube wells and to undertake minor investments to improve the supply of water. Both tenants and landowners will also use whatever political influence they have to induce the government to provide more and better large-scale irrigation facilities" [22, p. 1118].

In countries where an irrigation economy based on diversion preceded the need for modern groundwater institutions, these institutions could be built on the experience and mental attitudes already formed. These relations between groundwater institutions and surface water institutions I have traced elsewhere [6]. But such experience and such attitudes are not available in northern India. There, water institutions must be created from scratch.

The green revolution has created a need for more water. Groundwater tables are beginning to fall and will force the replacement of the Persian wheel by deep-well pumps. Increasing size of farms, related to the green revolution, will operate in the same direction because of the Persian wheel's relatively low capacity and high labor requirements. Increased irrigation will increase the need for drainage. Water allocation problems between users, between uses, between states and regions, between areas of origin and areas of destination, and between state and federal jurisdictions loom on the horizon.

To solve these problems, groundwater laws are needed to regulate the number and spacing of wells, the quantities pumped per well, the periods of pumping, and the provision and operation of recharge facilities. This will require adjudication of water rights and integration of groundwater and surface water development and, thus, an integrated water-rights and management system.

As a key element of such a management system, the water district has proved its usefulness in the United States and elsewhere. It is flexible with respect to its role as a part of local and regional government. It is flexible also with respect to the participation of social groups outside of agriculture that need additional water supplies. Water districts, possibly with greater governmental participation and supervision than in this country, are needed.

Water institutions of this kind will develop over time. But the individualism of the farmer, the local community, and the region, shaped over centuries in an irrigation economy dominated by the Persian wheel, requires a special effort by researchers and policy-makers to create and to make acceptable the water institutions that are needed. Complacency based on a simplistic doctrine of the role of institutions in economic growth is not at all warranted and will become dangerous if effort in research and in public policy is thereby deflected from this important area.

What India's agriculture needs most at the present juncture are competent economists, fully aware of the intricacies and the difficulties in the development of water institutions. Otherwise, the cornucopia of the green revolution may indeed prove Pandora's box, to paraphrase the title of a perceptive recent paper [29]. A laissez-faire attitude toward institutions is no less inappropriate than regarding them as constraints.

POLICY AND NON-POLICY IN FOREIGN TRADE

CHAIRMAN: JIMMYE S. HILLMAN, UNIVERSITY OF ARIZONA

Technology and Neo-Mercantilism in International Agricultural Trade

H. B. MALMGREN AND D. L. SCHLECHTY

WHILE developments in agricultural trade in this decade have been reasonably favorable, the underlying trend and some recent developments suggests a very difficult and dangerous period ahead in the 1970's. The results of the Kennedy Round trade negotiations were clearly beneficial for certain commodities. Agricultural trade has generally been increasing. Among the OECD countries, which are the major trading countries, it increased by 6.5 percent per annum from 1960 through 1967 [5]. But in spite of this overall progress, some of the general problems raised by other writers in the recent past are even more threatening now [2, 4]; and there are technological and policy developments that add new complex dimensions.

All countries were aware of the need to provide for expanding trade opportunities for agriculture during the course of the Kennedy Round. However, the substantive negotiating sessions in agriculture came too close to the end of the Kennedy Round talks to allow time for negotiating fundamental changes in access to markets or in national farm policies. The liberalization that took place was therefore modest in character.

The New Mercantilism

During this period the general level of protection in the European Economic Community (EEC) rose as a result of the implementation of the Common Agricultural Policy (CAP). The degree to which that protection has risen for some of the major farm commodities has not been fully realized. If the total charges of the variable levy system at the EEC border are converted into ad valorem equivalents, some interesting comparisons can be made between the pre- and post-CAP protection levels (see Table 1): For BTN Chapter 1, Live Animals, protection rose from 14 percent in 1959 to 49 percent in 1968; for meat, the rise was from 19 percent to 52 percent; for dairy produce, from 19 percent to 137 percent. Though not shown sep-

[a] Data for pre-CAP protection (1959) taken from report by Committee on Economic Development, *Trade Negotiations for a Better Free World Economy,* Library of Congress Catalog Card No. 64-20846, page 79. Post-CAP protection estimated from pre-Kennedy Round tariffs, adjusted to include 1968 import levies. Post-Kennedy Round tariffs would be somewhat lower for certain non-variable levy commodities.

[b] Brussels Tariff Nomenclature.

Source: Estimated from unpublished data in the world trade and tariff computer tabulations developed by the Office of the Special Representative for Trade Negotiations, Executive office of the President, Washington, D. C.

arately, for butter alone, the increase was from 30 percent, pre-CAP, to 350 percent, post-CAP. In cereals, the protection rose five times—from around 14 percent, pre-CAP, to 72 percent, post-CAP. In contrast with these phenomenal rises in the level of protection for major commodities, there have been some modest declines, mostly in complementary, noncompetitive imports, or in products where there has not yet been applied a common price policy or variable levy system. For the principal nonvariable levy commodities, like soybeans and soybean products, tobacco, and canned fruits and vegetables, the United States and other countries hold negotiated tariff concessions, and the introduction of the levy system would constitute an impairment of exporters' rights. Nonetheless, the EEC has contemplated breaking its undertakings and introducing the levy system, or introducing other protective devices which might have a major protective effect.

Because of these dramatic increases in the level of protection in the EEC, the Community is the most highly protected area for agriculture in the world. With the variable levy, the protection level is about triple that of eight or nine years ago prior to the CAP and many times above that in the other major developed countries.

There has been an argument often used by defenders of the CAP that the level of exports from the United States and other major traders would continue to rise, regardless of the "system," because of the rising demand for both food and feed. Until 1965–66, U.S. agricultural exports to the EEC did indeed continue to rise. But since then there has been a reversal, and we now appear on a downward path. In fiscal year 1969, total U.S. agricultural exports to the EEC were $1.3 billion, seven percent below that of fiscal year 1968. This represents a 19 percent drop ($300 million) in the past three years. The items subject to variable levies rose until the 1965–66 peak, when they totaled $737 million. The level for these same export products for fiscal 1969 is $441 million, a decline of nearly 40 percent in three years, while nonvariable levy items remained about the same. The rise until 1966 is also worthy of comment; until that time, there was no CAP for many products—only certain transitional price ranges. Towards the end of the Kennedy Round, the EEC, in a series of marathon sessions, reached internal agreement on common price levels, which tended to approach the highest individual country level. Consequently, the new import protection levels had also to move up dramatically. Thus, the real bite of the protective mechanism of the Community's CAP was not really felt until the common prices began to be reached in 1966 and 1967.

This is not the whole picture, however. While increasing its import protection, the EEC has simultaneously been raising its level of domestic production. Both yields and total production of the major commodities have been rising rapidly (Table 2). The rapid growth in output has been encouraged by high support prices and protected by a levy system which essentially converts imports into residual supplies. The support prices for cereals, for example, are about double the average world market level. Total EEC grain production has risen 20 percent in this decade, largely

Table 2. Index of EEC production and yield of selected agricultural products by year[a] (1959-60 = 100)

Item	1959 -60	1960 -61	1961 -62	1962 -63	1963 -64	1964 -65	1965 -66	1966 -67	1967 -68	1968 -69

on the strength of a 34 percent improvement in yields that also reflects new technologies. Total coarse grain or feed grain production rose 37 percent since 1960 and yields increased by 38 percent. The rising internal production in turn results in pressures to expand exports. With the high internal market prices, exports would not be possible without some special export assistance mechanism. The so-called restitution system of export payments was designed to carry out this function. Initially, the concept of the Common Agricultural Policy was that of a system with high prices, like an island in the sky, with a bridge up to that island in the form of the variable import levy system, and a bridge back down to the world market level via restitutions. Restitutions were theoretically to be established at a level equivalent to the import levies. On a feed product, such as poultry, exported chickens would theoretically benefit from a restitution payment equivalent to the import levies on the feedgrain incorporated in the exported birds plus a standard amount. In practice, however, the restitution system has lost this theoretical tie to the import levies in many cases, and the restitution payments are often simply set at levels sufficient to make the export competitive in any market of destination. In other words, the payments have no technical limit in some cases, designed as they often are now to beat the best price of the lowest competitor.

These restitution payments, or subsidies, have been especially troublesome in certain commodities: poultry generally, barley and wheat into the Far East, lard into the United Kingdom, dairy products to all destinations. The outlook is that these subsidies will be even more aggressively used in grains generally, as EEC surpluses begin building up to serious levels.

The poultry problem is a good example of the dangers that can result from this system. Import protection was tripled through the introduction of variable import levies in 1962. This brought about a substantial drop in imports ($33 million in one year from the United States alone). On the other side, as EEC subsidies necessarily affect the position of all poultry exporters, the Danes, who are major exporters, have been encouraged to continue and expand their own subsidy system (known as the "Home Market Scheme"). Importing countries in turn, having some home production of their own, are under pressure to increase the level of import protection if their markets are relatively open to imports. The Greeks established their own variable levy system to protect against such abnormally low-priced imports, and the Austrian Government recently introduced a minimum import price scheme of its own. In reaction to this highly distorted situation, the U.S. Government resumed its own poultry export subsidy into Switzerland in 1968, to make our exports competitive and at the same time dramatize the absurdity of the subsidy policies of other countries.

Thus, the dimensions of the protectionist, mercantilist aspects of the CAP go far beyond the question of the import levy system itself. The CAP system could have been operated in a less damaging manner. For example, the import levies could have been used to limit distress selling, or abnormal pricing by state trading nations. But the Europeans seem in practice to have opted for a much more import-protective and export-aggressive usage of the system. Because of excessively high protection, exporting countries find themselves competing more intensively in other markets to which they are diverted. Compounding this problem, EEC subsidies put heavy downward pressure on market prices for exports into third markets. The CAP has thus become truly mercantilist: its workings result in reduced imports, increased home production, artificially assisted exportation, and discouragement of exports of other countries into third markets.

These developments would be harmful enough by themselves. But there is the real likelihood that the practice will spread. Both political parties in the United Kingdom are advocating increased self-suffiency in agriculture. The minimum import price scheme, which was introduced in 1964 for grains, is highly protective. The Economic Development Committee for Agriculture was established to develop import-saving policies. The Ministry of Agriculture has followed its general proposals to stimulate home production and has agreed to pursue policies to cut back imports of agricultural products to save about $400 million annually by 1972–73. In the next year or two, the nature of import protection will be reviewed if the U.K.-EEC negotiations take place, leading toward the entry of the United Kingdom into the Common Market. The likely result of U.K. entry will be adoption of the variable levy system and an alignment to high support prices. This will raise the level of protection on agricultural imports into the United Kingdom, encourage home production of cereals and meat, encourage purchase of French and German wheat and feed as a substitute for imported wheat and feed from third countries such as the United States, and thus further increase competition in the remaining markets. Moreover, the costly accumulation of surpluses within the EEC could be greatly relieved by this opening of the U.K. market, especially for grains, dairy products (particularly butter), and sugar. With a reduction of the pressures on the member countries of the EEC resulting from costly stockpiling, there is less likelihood of a fundamental change in the EEC's own internal policies.

In Japan, a major agricultural importer and the largest market for U.S. agricultural products, the trend was good until about 1966. But Japan also is now suffering from the consequences of high support prices, mainly in rice (the rice support being nearly triple the world price level). There must soon be domestic diversion of production to other commodities to relieve the indigenous rice surplus being acquired by the government at great cost. This could easily result in increased pressures for new protection measures or at least maintenance of existing agricultural quota restrictions which are contrary to Japan's GATT obligations. The implications of the rise in rice supplies alone could be broad. First, there is consideration of a curtailment of wheat imports, as recommended by the Japanese Federation of Agricultural Cooperatives. Second, imports of rice, which dropped to insignificant levels in 1968–69, will tend to remain very low, weakening the world demand for the increased rice production of the developing countries. Third Japan will grant some of its food aid commitments under the International Grains Arrangement of 1967 in the form of rice, which will detract from the development of intra-LDC trade in rice.

The developments in other major producing and trading countries are also in the same direction, particularly in grains generally. The one positive sign in terms of changing public attitudes toward production restraints is in wheat, in Australia and Canada. The change here is rapidly becoming necessary because of shortages of storage capacity and rapidly increasing world surpluses of wheat.

Even in the United States there have been growing pressures for increased agricultural protection. Existing protective systems have been used more actively in the last two years. In the case of dairy imports, emergency quota action was taken against certain dairy products, including some types of cheeses in addition to those already under quota. The main reason was the extraordinarily low price levels for some of the imports, resulting from large subsidies by the EEC and certain other countries. Given the enormous surplus of butter in Europe, it is not surprising that the EEC was tempted to try to move butterfat in various forms with the use of unusually large export aids. Nonetheless, in spite of the reasons for the U.S. actions, it can be said by other countries, with some justification, that our overall quota levels for dairy imports are excessively restrictive, holding imports to about one percent of domestic production. In beef, the present quota legislation, introduced in 1964, does not formally apply, since imports have not reached the so-called trigger levels that would bring quotas into effect. However, imports have recently been very close to the trigger levels. Consequently, the Executive Branch was forced to warn exporting countries in 1968 that they would bring quotas into place unless they restrained exports below certain specific levels. In this way, an informal, voluntary quota system came into effect in 1968 and is still operating. The result has been significant restraint on the levels of exports from both traditional exporters (Australia and New Zealand) and from a number of developing countries in Latin America.

Economic Regionalism

These forces are working themselves out in conjunction with another set of mercantilist forces arising out of economic regionalism. Clearly, when nations join together in a trading bloc, there is the danger of trade diversion as well as the prospect of trade creation. The effects of the CAP on world trade have been changing. As already suggested, the odds are great that U.K. entry will exacerbate the difficulties. There will consequently be considerable incentive for other neighboring countries to become part of the system, opening these markets more directly to the EEC member states while closing them to third country exporters like the United States. The costs will be high to such new members, but those countries seem willing to pay the costs. Moreover, if the political decision is put frankly, it is a question of accepting a heavy price for agricultural readjustment in exchange for greatly improved industrial access and exposure to the kinds of competition which ought to stimulate industrial growth. Since countries like the United Kingdom are necessarily faced with major agricultural adjustment needs anyway, and those adjustment programs that are being given consideration are already protectionist in character, there is doubt that the agricultural costs will ultimately deter entry.

Economic regionalism has had its bad effects felt in agriculture elsewhere. The increasing preferential tendency between the EEC and other countries is having a diversionary effect in a number of commodities. The preferences of Greece and Turkey, unjustified by any reasonable construction of the allowed types of association in the GATT rules, have an adverse effect, as do the special relations with African and Mediterranean countries. Within 1969, for example, the EEC arranged for new preferences on citrus products from Tunisia, Morocco, Spain, and Israel, which results in discrimination against numerous other suppliers, including the United States. More recently, the EEC decided to seek establishment of a general preferential arrangement with Spain and Israel.

The developments among the developing countries have not been favorable to third countries either. One of the effects of the Latin American Free Trade Area has been to raise the protection against certain agricultural products from outside the group while providing preferred access to those within. Of course, if the LAFTA were a true customs union, preferential access among the members would be acceptable. But it is not a customs union, and there is little prospect of it becoming so in the reasonably near future. In the meantime, outsiders have been harassed by a variety of problems. For example, U.S. exporters of fresh fruit face increasingly high, or prohibitive, import barriers into the Latin American economies, while some of these same countries export to the United States in increasing quantities, as well as to each other.

This tendency toward regionalism is growing. It need not necessarily result in damaging distortions to third country trade, but it has tended to do so thus far in agriculture.

The Role of Technological Change

Past improvements in technology, leading to steadily improving yields, have played a significant role in the rise in world production. But those developments have been orderly until recently. In the next few years, world grains production, particularly in Asia, will be greatly affected by the recent introduction of the new high-yielding varieties of wheat and rice. The area planted to these high-yielding varieties in Asia, for example, have increased substantially from 4 million acres for the 1966–67 crop year to 27 million acres for the 1968–69 crop year [8]. The impact of these new varieties will be great, though the exact dimensions are as yet uncertain [3, 7]. The developing countries are not only hoping that use of these varieties will bring about a quantum change in their economic position; they are actually planning on major changes. A number of them expect not only to reduce imports drastically, but to become self-sufficient and to begin exporting on a large scale. The change from net importer to net exporter position for some of them is part of their overall economic development plan.

Questions immediately arise: What will be the effect in terms of adding to the world commercial grains surplus? Will the increasing self-sufficiency of some of the larger developing countries mean the reduction of world market potential, instead of the rise some had hoped for in previous years? Will world trading prices, already subject to the pressures of export subsidies and production stimulation policies in the developed countries, be further depressed by the rising commercial position of the developing countries? If so, will this bring about the same kind of mercantilistic policy reactions in the developing countries as has been seen in the developed countries, with all the consequent heavy costs of export subsidies and income support programs?

Another set of problems arises out of the international transmission of new technology. One of the best examples is again the case of poultry. The newer methods of chicken production were first introduced in the United States. Americans then provided technical assistance to Europeans with a view to increased sales of feed and chicks. The improved efficiencies in European production might have reduced the pressure for higher levels of protection as a result of the declining cost of production. But this did not happen. Instead, increased capability to produce at home simply added to the pressure to substitute for imports. The less efficient producers who were subjected to increased competition from internal EEC competition insisted on increased protection against somebody—and the somebody had to be the outside world since the internal market of the EEC had to be free of restrictions. In some smaller countries, the improved technology provided increased incentives to shift over to, or remain in, poultry production. With the advent of increased production and heavy export subsidies from the major exporting countries, such countries found themselves with a semi-efficient industry suddenly challenged by artificial prices and in need of protection. Thus, the steady transfer of technology from the countries originating new methods to other countries has often simply added further protectionist incentive.

A third set of problems now facing us is the changing technology of animal feeding. Much of the change has of course been spurred by the changing price differentials among various feeds, which in turn were brought about by national policies. Countries are increasingly feeding wheat (and even recycling milk products back) to cows. New feeds are also able to make inroads. Fishmeal has been making major gains. The use of urea, one of the newer developments in synthetic feeding, is taking hold.

The combined effects of these three developments cannot be gauged at this time, but it is clear that major readjustments in trade patterns in the 70's are likely to arise out of these forces of changing technologies.

International Adjustment Problems

The technological developments, both those of longer term, steady improvement character, and the more recent quantum changes such as those made possible by the new varieties of food grains, should theoretically have reduced protectionist pressure. As efficiency improved, it might be expected that the need for individual product protection would be lessened. Events have not unfolded in this way, however. One response in Europe to increased efficiency and increased production has been to seek to raise the level of protection and of export aids. Another response to the production rise has been the conscious restructuring of price differentials between food and feed grains. The objective in Europe is to make corn expensive and wheat relatively more cheap for feed, so as to substitute wheat for imported feedgrains.

The general improvement in agricultural production coupled with a less rapid rise in demand will mean increasing supplies available for export. A recent OECD study indicates that the major developed countries have the prospect of expanding food production well beyond their own needs, without any changes in policy. For example, the net export availability of grain of the OECD countries plus Oceania would rise from 20 million tons in 1961–63 (6 percent of production) to 90 million tons in 1975 (19 percent of production) and 121 million tons in 1985 (21 percent of production) [6].

Against this background, the consequence of the interaction of conflicting national and regional agricultural policies will be to create a major world trade and production adjustment problem. The present crisis in world dairy trade, characterized by heavy surpluses and extensive subsidization, is not an isolated problem. It is simply an example of the adjustment problems to come in other commodities. Particularly in wheat and rice, the increased self-sufficiency objectives of many countries, both developed and developing, will limit the opportunities for unloading domestic surpluses of those countries which traditionally export. The developing countries, who have put so much of their hopes on the Green Revolution, may confront a very difficult market. Moreover, the possibilities for relieving their difficulties through regional arrangements with other developing countries are endangered. One of the major incentives for regional cooperation would have been sale of agricultural commodities; but if these nations become more or less self-sufficient, they may have substantially reduced incentives to work more closely together.

One of the major adjustments will be a consequence of the slowly changing relationship between food and feedgrains, as foodgrains are increasingly utilized as feed ingredients because of the rapid rise in wheat and rice production. One of the interesting analytical questions on which there has been little work, is the relationship between rice and wheat, and the relationship among rice, wheat, and feedgrains taken together. Looking at the adjustment problem generally, some countries are tending to see their salvation in increasing production of animals, and increasing demand for animal proteins in the diet. There is room for maneuver here, but countries may well follow again the patterns of the past and attempt to make the adjustments behind increasing protection, thus starting a new cycle of major adjustment problems.

A major force, which eventually ought to push countries toward consciously planned and economically efficient adjustment policies, is the rising cost of domestic production policies and export subsidies. But these costs can continue to rise for a time in some countries. In the EEC, the home costs are far higher than they appear. The national programs are additional to the Community programs, and many of the national programs are buried in the budgets of many ministries in addition to the agricultural ministry. Moreover, consumers pay a significant portion of the costs through the very high level of prices. A not unreasonable estimate done informally within the U.S. Government sets the cost of the Common Market agricultural program at about $15 billion a year.[1] Of course, any such estimate of cost does not reflect the cost of diversion from alternative resource allocations that could have higher social and economic returns. So long as the costs are diffuse and difficult to pin down, there will remain room for further rises. Moreover, taking into account the political objectives of the European Community, there are many who argue that the farm costs are simply part of the political cost, and that an appropriate mercantilistic use of the CAP mechanism will relieve much of the burden. Since export subsidies are at least in part financed by import levies, they argue that further room for increased subsidization exists. Others argue that it is cheaper to subsidize almost to any level, rather than build storage and incur storage costs where surpluses exist. For a time the United States can step up the cost pressure on other countries by lowering its export prices, either by increased use of subsidies or by decreased support prices in the United States. This indeed is a necessary ingredient in the search for an easing of the conflict in national policies, because the costs to other countries will probably have to rise somewhat further before they will be politically prepared to make major policy changes. But this means that the world faces a kind of trade and adjustment problem that is most difficult—a problem the major powers can ultimately cope with, at great cost, but with which the developing countries and the smaller developed countries cannot unless there is some new international discipline introduced.

The Need for Coordination of National Policies

There is, then, urgent need for some new kind of approach to international negotiation and coordination of national adjustment policies in agriculture. There are many complex analytical questions which must be faced up to in the search for any international principles, guidelines, agreements, or understandings. Countries will continue, as they have in the past, to accuse each other of maintaining systems that provide greater protection, production incentives, and export aids. There can be no progress unless better measurements can be found for the economic impact of the various national policies. The EEC suggested the *montant de soutien* technique during the Kennedy Round, as a means of measuring the margin of support [2]. While this particular approach proved unworkable, there is a need to find some technique of quantifying the level of agricultural support and the degree of price distortion from one country to another and from one product to another.

---

[1] The direct budget expenditures at all levels of government amounts to about $8 billion; the cost to consumers in prices above world levels, about $6-7 billion.

One interesting analytical question has come up in the context of proposals to limit or eliminate subsidies. Naturally, the question arises in debate among countries as to what levels to set for limiting subsidies, taking into account the effects of home production and marketing incentives. What is an efficient international price?[2]

Although there will be many who have difficulty with the idea, it will be necessary to examine in some detail whether some types of access commitments and price arrangements, or subsidy limits, are necessary, at least for a transitional period; and whether levy systems might be put under international discipline, and if so, how. Economists are badly needed to turn attention to these trade questions so as to lay the basis for sensible international discussion.

It is thus no longer sufficient to say that the international agricultural market will somehow take care of itself and that the best trade policy is one of minimum intervention. Governments have already committed their economic systems too far to allow abrupt adjustment to free trading principles. Given the present world technological adjustment problems, the seriously conflicting national policies, and the resurgence of mercantilism, there is urgent need for governments to intervene to restrain themselves and to restrain each other. At this time it is not a question of free trade based upon open commercial competition, because governments have so heavily intervened. So long as governments play such a dominant role, any solutions must be related to government actions, require government commitments, and provide meaningful international guidelines for governments to live by. Without some breakthrough of this character many countries will face extremely costly adjustment problems. For some countries, particularly the developing ones, there will be even broader implications for their economic development and political stability.

---

[2] This question is even more complex when trade from eastern European nonmarket economies is considered, and the trade from these countries is increasingly important in world markets.

New Concepts and Methods in Foreign Trade Negotiation

ROBERT B. SCHWENGER

I PARTICULARLY appreciate the opportunity to discuss foreign trade policy at this meeting of your Association. The subject is officially "open"—much as it was just 25 years ago when I wrote my first foreign trade paper for your Journal as a by-product of work on the team that drafted the GATT (General Agreement on Tariffs and Trade) [7]. The government and Congress are again looking for a new program. The record of hearings held and official recommendations made in the past two years runs to some 7000 pages, and the debate continues.

Summary

That debate is taking place against the conceptual background known as "free-trade-versus-protection" which has traditionally framed foreign trade thought in the United States. This paper contends that the conceptual system, however socially useful it may have been during the 19th century when the nation was developing and consolidating in a colonizing, warring world, is irrelevant today. It highlights the wrong questions about our foreign trade problems. Therefore, the negotiating method based on those concepts has been working in reverse. Although directed to reducing trade barriers, it increases them. Although dedicated to peace, it stirs up international hostility over trade matters—often over minor ones. Worst of all, it militates against efforts to work out an alternative method of international trade discussion on the basis of a more pertinent set of public concepts ready at hand for the purpose. I will argue that governments should now by-pass the free-trade-versus-protection concepts, which assume an essentially isolated static, laissez-faire national economy. Instead, they should be guided by the general concept of their collective responsibility for facilitating the prosperity of a dynamic world economy. In foreign-trade-policy terminology, that concept may be called "free-trade-versus-economic-fragmentation" or, more accurately, "free-trade-versus-Balkanization." It implies a mixed-economy, competitive-representative process for the world. One method for governments to work toward that kind of free trade would be through open joint deliberation of all facts relevant to a trade barrier, followed by public national reconsideration of the barrier with a view to eliminating it or modifying it to serve its purpose with minimum undesirable side effects, and then public consideration by other governments of cooperating toward that purpose. This approach would contribute not only to efficiency but also, by denationalizing trade conflict, to the building of positive economic peace.

ROBERT B. SCHWENGER *was formerly with the U.S. Department of Agriculture and the U.S. Department of Labor.*

The Concept-Method Interface

As you can see from that summary, I take my assigned subject, "Concepts and Methods," to refer to concepts that pervade public debate and methods that governments formally announce. This takes us along a tortuous interface between science and art—that is, between social science theory and its application in governance. It is a tricky area for both theorist and official. It is especially dangerous for those who, like me, try to be dual purpose animals. Let me take a moment on this methodological point.

The role of the *social theorist* is threefold. First, he must perceive the real forces and trends that conduce to current social purpose as he reads that purpose (or, if he wishes to serve a group smaller than society, as his group reads it). Second, he must posit a model universe, incorporating as many as he can handle of the characteristics of the real world that are relevant to the purpose. Third, from his model, he must reason out concepts that can illumine for everyone the ways of accomplishing the purpose. The *policy official*, on his side, looks to the scientist's concepts for guidance in devising and support in making publicly acceptable methods of coping with real problems. Once publicly accepted, a concept, together with the assumptions built into it by its model, acquire a certain sanctity and resistance to change. Reality, on the other hand, changes rapidly. Different real characteristics become relevant and significant for social purpose; the model needs changing; the concept needs revision. The established scientist may be tempted to evade this challenge. He can say that his work is pure theory—or the exercise of, as your program so nicely puts it, the "tools of our trade"—leaving the real problems of society for the politicians and the general public. Or he may be tempted to patch up his model without retreating from his old policy conclusions. The official, of course, must go on dealing with the new problems, explaining his actions as modifications or exceptions to his announced method of acting.

At such times, the two may form a *defensive alliance*. Cooperation between social theorist and official is socially useful for assuring full public information regarding problems, policies, and proposals for change. But it can be a disservice if used to cover up the shortcomings of an out-dated model or, worse, to let such a model pass as the ideal to be achieved by a public program. Therefore, when re-examining the concepts behind a policy that is not functioning well, one must review the overall relationship of the science and the art, trying to avoid any subtext of unspoken values or assumptions.[1] To attack so broad a canvas in a half hour requires making assertions without sufficient qualification or demonstration. I hope we can share intuition—and allow reasonable benefit of doubt.

---

[1] For pioneering studies of this problem, see [2, 3].

Present Concept and Method

To begin with, the economic *concept* behind U.S. foreign trade policy is free trade. It is expressed variously as freer trade, trade liberalization, reduction of trade barriers, withdrawal of intervention in trade, and so on. Withdrawing government intervention permits the expansion of mutually profitable trade. Then, by the operation of the mechanism of comparative international advantage, national resources are directed toward more efficient use. National income is increased. The sway of this concept over public policy in 1969 was evidenced by the general approval of opinion leaders when President Nixon said he was for freer trade.

But free trade is an "empty" concept—incomplete. It can be defined only in terms of something *not* done. Public power and public funds must not be used to check the flow of imports (or stimulate that of exports). Such government actions are called "protection" because they shelter or otherwise help domestic producers who must compete with foreigners. Free trade is zero protection. Free traders agree that if protection is withdrawn too rapidly or if there is substantial domestic unemployment or underemployment, the forces directing resources toward more efficient use may cause unusual suffering and loss. The domestic market for a product may be "disrupted." Some continued protection may, for a time, assure the most efficient resource use and the maximum national income. Also, some protection may be needed to develop a new industry. On the other hand, most public arguments for protection—whether or not logically consistent with the free trader's economic model—accept free trade as a desirable long-run goal. Although they differ as to which producers should be protected at a given time and for how long, free traders and protectionists make up a sort of community, contending publicly over common conceptual ground hallowed in U.S. history. When the President added to his freer-trade statement certain assurances of intervention to prevent disruptive foreign competition, the applause was widened—if not intensified.

There is one important *non-economic concept* usually associated with the free trade argument for our trade policy. Trade is mutually profitable. It strengthens the fabric of *international peace*. Government barriers to trade emphasize conflict of interests among nations and lead toward war. Removing trade barriers removes a cause of war; negotiating to reduce them reduces the danger of war.

The official *method* of reducing trade barriers is through *bargaining with foreign governments*. We tried tariff bargains from time to time through much of our history, but it was in 1934 that they became the core of our policy. The high 1930 tariff had helped deepen the depression. Other countries had retaliated in what proved a kind of reciprocal economic suicide. The world had learned that the trade purposes of almost any government act could be frustrated by a foreign counter act. Cordell Hull had the genius to forge a broad consensus of free traders and protectionists by reversing this. We would negotiate to get a foreign country to reduce its barriers to our exports in return for our reducing our barriers to imports. By selecting barriers on products imported principally from the other country, by negotiating with all countries, and by making each reduction applicable to imports from all countries, we would eventually reduce all barriers. The negotiations were held in secret. It was a sort of game; the participants pretended to bargain vigorously, but all were assumed to want the same final result. By moving cautiously and in a period of economic recovery, we minimized disruption. After the war, we were in a position to persuade all the large trading countries to join us in the GATT—with its "rounds" at which many pairs of countries bargain simultaneously under common general rules. There have been six rounds, from the seven-month "first Geneva" of 1947 to the almost interminable "Kennedy Round," which ended, technically at least, in 1967.

Left Behind by Changing Reality

The concepts and the method presented in that oversimplified sketch have made their great contribution. However, judged by their own value premises—efficiency and peace—they do not now serve a useful public purpose. The free-trade-versus-protection *concept* distracts public attention from the essential issues facing us because it conjures up a picture—a "model" if you please—in which three vital characteristics of today's world are not adequately incorporated. The three are the flowering of a world economy, the speeding up of dynamic growth, and the evolution of a competitive-representative, mixed-economy process. Let us consider each of these and how it brings the wrong questions to public attention.

A world economy

The free-trade-protection concept assumes a distinct national economy with a production process and income level essentially separate from those of other countries. The basic theory, comparative international advantage, deals with the effect of opening an isolated national economy to trade. The proof of the wisdom of opening trade is the more efficient use of national resources. (Proponents argue that foreign resources are also used more efficiently in most cases, but this is treated as of secondary importance if it does not follow automatically.)

In the early 19th century, when our free-trade-protection debate began, the separate-national-economy assumption had a substantial basis in fact. Moreover, we were a young, developing nation. The great powers were contending for colonies and discouraging the industrialization of new areas. Concepts based on the national-economy assumption bolstered those forces (toward national consolidation—against sectionalism) that far-seeing men then recognized as conducive to high social purpose.

In today's environment, however, it is most difficult to justify an economic model that posits a distinct national economy. The fact is that national economies are rapidly becoming interdependent parts of a world economy. Technological advance is daily stepping up the degree of their interpretation. Governments have more common interest than conflict in trade problems. Each national economy now achieves its greatest potential by functioning as part of a single world-production-consumption continuum. No national economy is viable when isolated, except in the rueful sense of being able to weather catastrophe. And, in the world of the superbombs, it would be difficult indeed to dispute that this common-economic-interest trend conduces to the self-interest and highest social purpose of any group one can conceivably serve—even weapons manufacturers, if they value posterity or their own lives. A foreign-trade-policy concept and method, to serve the national interest today, must assume a dependent, partial, national economy. (Incidentally, theorists could incorporate such an assumption into the static theory of international trade by simulating a complex world economy and then "wounding" it with controls introduced along an arbitrary geographic line within it. The implications of such an approach might be far-reaching for all international economic matters.[2])

Accelerated growth

The second shortcoming of the free-trade-protection conceptual system is its static base. It assumes a given "state of the arts." This is most strikingly manifest in a priori public concern with adjustment and with market shares, that is, anticipation of loss to a given domestic industry when foreigners expand their sales, even though the domestic industry is prospering. Taken together with the national-economy preconception, this produces some weird results. It is not unheard of for a domestic industry, which is the world leader in its product and which is booming, raising prices, investing in new plant, and advertising for more workers—it is not unheard of for such an industry to complain that it is losing a *share* of its market to imports and to get wide enough public sympathy so that Congress and the Administration put diplomatic pressure on foreign governments to restrain the imports. This, of course, is a rough description of the steel case in the United States—probably the textile case also. And most of the quota bills now in the Congress are designed to protect thriving industries from the anticipated trade consequences of world technological advance and growing American demand. Saddest of all, perhaps, is the poultry case where we and the EEC have managed to turn a technological breakthrough in the production of desperately needed animal protein into a full-scale economic war over a small, temporary trade shift due to the natural lag in the spread of the new technique. For a socially useful perspective on such world economic growing pains, one must take dynamic growth for granted. Innovation has become a way of life in much of industry and agriculture. We are, or soon will be, physically capable of producing enough to supply a decent minimum of necessaries to every human being; as we work at doing so, there will be demand enough to resolve almost any future trade problem. I understand that truly dynamic models—incorporating the unpredictable—elude scientists; perhaps concepts relevant to great change can not be derived from limited models. Nevertheless, intergovernmental discussion must conceive of trade as part of a world economy that is expanding rapidly and will expand ever more rapidly in the future.

---

[2] This suggestion was originally made in [4].

The competitive-representative mixed economy

The third archaic assumption of the free-trade-protection concept is that trade within the national economy is already "free." If protection were removed, it is implied, laissez-faire would prevail, and the market would adjust the production-distribution pattern to a new equilibrium. In fact, of course, a mixed-economy, competitive-representative process has evolved within modern industrial countries. The production-distribution pattern is determined by the market power of a constantly shifting set of individuals, firms, associations, combinations, labor unions, community groups, clubs, societies, public corporations, "sub-governments" (as Douglas Cater dubbed them), and so on.[3] All of them compete, in a sense, for the custom and support of the paying and voting public. But all of them also try to influence government. And government intervenes as it considers necessary to modify the benefit pattern. It intervenes through subsidies, price supports, wage supports, transportation regulations, taxes of all sorts, social payments, procurement practices, administrative delays, prescribing standards, and innumerable other ways.

Now, government actions that influence domestic trade usually influence foreign trade also. (In fact, many of them are efforts to deal on a domestic policy basis with problems of the growth of the world economy.) Hence, they can be used to help domestic producers compete with foreign producers. They are protection under the accepted concept. The fashionable term for them is Non-Tariff Barriers (NTB's). Free trade means their discontinuance. The GATT rules require, in general, that those not discontinued be operated so as not to distort foreign trade. But the NTB's are constantly changing; they are thought of as determined primarily by domestic intervention purposes. Therefore, the GATT requirement is often ignored. A limited amount of reciprocal ignoring might not make too much difficulty. But governments that protest more and more foreign NTB's have had to submit to more and more official foreign criticism of their own domestic economic and social policies that affect trade. This creates misunderstandings and bitterness.

---

[3] Cf. [1].

It is not really surprising, then, that *the method of bargaining trade barriers down,* publicly guided by a concept with such serious blind spots, *has contributed in recent years to putting barriers up.* Its harm may have begun to outweight its benefits as early as the mid-1950's, by which time, with some help from inflation, it had reduced most of the depression barriers to little more than nuisance levels. By the end of the Kennedy Round, the negotiations were bogged down in problems they had not been designed to solve. It was no longer clear what mutually valued common objective sustained the concert of bargaining nations. Each government tended to defend its own measures as being in the overriding national interest and to attack foreign measures as being unfair or illegal distortions of trade patterns. Cordell Hull's great consensus of free-traders and protectionists had fallen apart under these reciprocal attacks on measures traditionally considered domestic. The adversary, secret procedure of the little bargaining game had degenerated into bitter intergovernmental wrangling and public recrimination among high-level officials. That is where we are today in public posture. Governments, ostensibly seeking trade agreement, convey the impression that there is an economic basis for international hostility. The secret discussion format gives little occasion—and the accepted concept provides no rationale—for public deliberation as to which national measures affecting trade might be desirable or which not. Instead, the whole process appeals to emotional economic nationalism. It creates public support for the indiscriminate, "retaliatory" increase of trade barriers. This carries over to intransigence on other foreign economic, diplomatic, and even military issues. The trade-peace concept itself seems to work in reverse. Our negotiating method has a number of other disabilities, but these are probably the major ones [5].

Intergovernmental Cooperation—As Improvised Exception

Meanwhile, of course, officials go on living with the trade consequences of one another's intervention. When substantial real problems are created, governments usually come to an understanding in some way—formal agreement, tacit consent, or something intermediate—outside the intention of the free-trade concept and contrary to the rules of the bargaining game. Sometimes the intervention involved is a tolerated substitute for a trade barrier that has been bargained away. In the very first trade agreement completed under the Hull program in 1934, we cut the duty on our largest competitive agricultural import—sugar—a full 50 percent; but, at the same time, we put on a system of variable import controls to support the U.S. price, giving foreign suppliers some benefits also. Trade policy officials boast of the large duty reduction, but they wink at the absolute government control of the trade. At other times there is accommodation and positive coordination of intervention. My 1945 Journal article reported a plan to make an exception from the bargaining rules for certain crop programs, provided there was agreement on intergovernmental coordination looking toward a comparative-international-advantage production pattern [7]. When I reported at your 1957 Christmas meetings on the clauses of the GATT incorporating this exception [6], I had trouble getting my paper cleared for publication because that part of the GATT was being flouted by the United States. In the name of free trade, we were discouraging any intergovernmental commodity discussion whatever. But reality soon changed that. A PL 480 market-study team in Brazil that year discovered that trees already planted would shortly be bearing twice as much coffee as the world could consume, and planting was continuing. Important Latin-American economies were threatened. We began actively to promote the coffee agreement that we had been actively opposing. In one way or another governments have coordinated their intervention, as exceptions to the trade-freeing rules, to prevent extreme prices for a number of primary products, to block non-essential imports into redeveloping Europe, to move industrial-country food surpluses to hungry people in poor countries, to prevent dissipation of less-developed-country foreign exchange on luxuries, to limit the rapidity of trade increases considered disruptive, and to do many other things—small and great, narrow and broad—that the free market would not do but that governments considered necessary. Some conspicuous current cases are the arrangements for restraint of exports of meats, textiles, and steel. President Nixon's assurance regarding market disruption referred to this type of arrangement.

Guidance and Public Surveillance Needed

The successes and the failures of these efforts to solve problems through coordinated action point the way to the general concepts and formal methods needed today. Five points may be of special note. First, great good has often been done. Second, there has been abuse of both political power and secrecy. Third, there has been wider understanding and lessened intergovernmental conflict over the specific problems involved. Fourth, the GATT surveillance through the secret review of periodic reports has not been very effective. Fifth, the irrelevance of the free-trade concept for coordinated action and the lack of general agreement on any relevant concept have, on the one hand, facilitated abuses and, on the other, given an aimless, ineffectual quality to much that governments should have done proudly.

Proposed Concept: Collective Responsibility

Fortunately, a relevant and familiar public concept is ready at hand for governments to use. If one pictures a growing, integrating world economy, one is struck by the collective responsibility of governments to represent the interest of all people in its effective working. Moreover, one can see that, for that responsibility to be discharged well, something resembling the representative-competitive, mixed-economy, political-social process is needed at the international level. As a matter of fact, many of the components have been forming slowly for years [5]. All sorts of individuals and groups have international connections. The management and finance components have recently been developing quite rapidly. In fact, there is serious concern that they may outgrow governments. In the non-trade-policy areas—such as monetary management and the maintenance of business activity and employment—governments have been recognizing their mutual dependence through cooperative action. But in the trade field, the non-intervention concept and the adversary method undermine their own adaptations to reality. They hobble cooperation.

Proposed conceptual system: free trade versus Balkanization

Interestingly enough, the collective-responsibility concept applied to the trade field immediately suggests free trade. In fact, for many non-technical people, the common-sense meaning of free trade implies collective responsibility. You have all heard the popular dictum: The United States became the world's leading industrial country because we had free trade from ocean to ocean while Europe was cut up by national tariff walls. Unfortunately, experts and officials often take this public theory as support for their entrenched concept and method. But consider the implications of it! In the socio-economic process that it implies, trade is not free from government intervention—not at all! It is subject to all sorts of surveillance and interference in the public interest. In our great ocean-to-ocean free-trade area, government is *expected* to intervene to affect trade in connection with the supply of public necessities, natural monopoly, misrepresentation, private restraints on trade, public health, public morals, large crop surpluses, exploitation of workers, cutthroat pricing, excessive market power, and anything a majority of the people want it to affect. What it must *not* do is interefere with the movement of trade across fixed geographic lines within the economy. It must *not* allow us to be carved up into state economies or regional economies. This is the foreign-trade freedom that would advance national interest within an up-to-date world economic model. This trade freedom is not defined as the absence of protection, i.e., the absence of intervention affecting trade. It is defined as the absence of such intervention applied along arbitrary geographic lines. It is freedom from economic fragmentation—or, as it used to be called, Balkanization.

The deliberating method—eliminate intervention or coordinate it

With these concepts in mind, one can see the direction sovereign governments must explore to discharge their collective responsibility for letting trade flow freely and for intervening as cooperatively as possible when the public interest requires it. The general procedure I would propose that they try involves three elements: deliberation, decision, and coordination. Governments would agree to a continuing multilateral forum for deliberation—open for the public to hear and to be heard. A controversial government action affecting trade would be discussed in the light of its announced purpose. The object of the deliberation would be a factual report on all of the economic effects of the action—domestic and foreign, direct and indirect, concentrated and diffused, immediate and longer term, costs and gains. Facts regarding actions of other governments affecting the same trade problem could be included. As far as possible, these matters would be quantified. (Here is work aplenty for dedicated economists.) There would be no façade of multilateral decision to be struggled for and then ignored. Hence, there would be no national positions decided secretly in advance of the discussion. Decision would be left to the acting government, committed to subsequent reconsideration of its action—through its own constitutional processes, but in public—with a view to (a) discontinuing an action it found no longer desirable and (b) framing any further action needed for the originally announced purpose in such a way that it can be accomplished with a minimum of adverse side-effect on the world economy, its own citizens, and citizens of other countries. All governments would be committed to consider cooperation toward accomplishing the public purpose of an action announced after such national reconsideration. This would initiate a process of informal public communication, coordination, and, as necessary, agreement regarding the original problem.

There would be an independent International Trade-Fact Authority responsible to legislatures—not to governments. It would consist of national Trade-Fact officers whose only responsibility would be to assure that both the international discussion and the subsequent domestic reconsideration were as fully informed as possible. They would have the necessary authority to know and to disclose facts (but not to counsel or take action). Thus, any action affecting trade would be informed and would be publicly understood in its relation to available alternatives.

Some Elaborating Assertions

That is the proposal. The details, of course, will not be easy to work out. I discussed a few of them in the J.E.C. paper mentioned earlier [5]. Let me conclude with a few assertions:

(1) Unlike the bargaining method of foreign-trade negotiation, the deliberating method would reinforce other U.S. policy. Thus, it would en-

courage intergovernmental coordination of necessary farm supports, instead of abetting economic warfare over them. It would facilitate cooperation to use the world's basic-food production capacity to feed the world's hungry. It would lead to the mutual understanding of one another's intervention needs that is required if industrial countries are to join purposively in the trade arrangements needed to speed the development programs of poorer countries. It might focus intergovernmental consideration of problems related to multi-national firms without inhibiting their imporant contribution to growth. It would remove an ideological and prestige problem from trade discussion with state-ownership countries. In short, it would make overall foreign economic policy more coherent.

(2) Functionally, the most important part of the proposal is the independent International Trade-Fact Authority. Unless one has participated in trade negotiations, it is difficult to imagine the enormity of the role played by misinformation, misunderstanding, and unrecognized ignorance. Problems become conflicts before common solutions are sought. With a citizenry informed by modern communication and expecting to see the social benefits of technology realized, public authority must support institutions for assuring the full availability of relevant facts and a public sense of involvement in solving trade problems. Only thus can there be the eternal democratic vigilance needed to maintain dynamic balance in the mixed-economy process.

(3) Last April, Secretary Stans proposed "open table" discussions of NTB's. This may be intended as a step toward non-adversary deliberation. Unfortunately, he simultaneously demanded quotas to "protect" a thriving American industry; he threatened indiscriminate protectionism rather than wait for open deliberation of the need for quotas. Is our policy the cooperative new approach or the pugnacious old one? I believe that it would help in this, and in all efforts toward economic peace, if political economists were to promulgate such concepts as free-trade-versus-Balkanization and collective-responsibility-for-the-world-economy.

(4) The greatest benefit from open deliberation would be the "degeographicalizing" or "denationalizing" of economic conflict—and the associated recognition of what I call the "ethic of economic agreement." Governments would not, as now, face one another as surrogate competitors. They would be committed to public joint weighing of all the information relative to a given trade barrier, including that regarding their own interest in changing their own action. The format of discussion would highlight the obligation, for the common good, to carry economic discussion to the point of full, reciprocal understanding, and not to let it break off into political power conflict among sovereigns. Against the fragmenting "multi-polarity" (to use Kissinger's term for it) of the world's sovereign-state political system, it would help bring to bear the real unity—the "uni-po-

liarity" if you please—of the world's integrating economic environment. Institutions which can do that are necessary foundation stones in any enduring structure of world peace.

Discussion: Policy and Non-Policy in Foreign Trade

JAMES G. KENDRICK

Malmgren and Schlechty have provided us with a detailed and far-reaching examination of the futility of trade restraint escalation. Their papers adds to the growing volume of current writings that are focusing upon the rising protectionist mood found both here and abroad.

Economists seem most flusterated when the political-economic real world ignores basic doctrine; and the free trade concept is as basic a doctrine as one can find. When an economist delves into his carefully acquired theoretical tool kit, he finds no instrument that will force an automatic return to the normative free trade model once trade restraints are employed as a major operational strategy among the major trading nations in the world. Unfortunately, as all of us have been forced painfully to learn, the real world does not operate entirely within the confines of economic logic. Many of our concepts of the theoretical operations of market economies are, in fact, based upon a whole set of political and social assumptions that can be both local and temporary.

JAMES G. KENDRICK *is professor of agricultural economics at the University of Nebraska.*

This observation concerning the lack of universality of models is neither original nor new, of course. In the early 1800's, Frederick List was documenting that free trade among nations would yield results only when that trade was among nations of similar economic and social conditions. Since most of our theoretical heritage is based upon static or comparatively static conditions, further troubles confront the economist when the real world adds the complicating parameter of dynamics.

I thus find an unfortunate emphasis in the Malmgren and Schlechty paper that might lead the casual reader to conclude that technology was the cause of rising protectionism in international trade and that negotiations among the nations might logically take the form of offsetting the effects of that technology. Certainly technology has increased the economic pressure for adjustments in resource location and use, which would then alter trade patterns. However, I am reluctant to place technology in the villain's role, for technology may be only a by-product of generally dynamic conditions.

I would also respectfully differ with Malmgren and Schlechty in their suggested approach to reduce these barriers. They rightly suggest that there is a need for coordination of national policies among the trading nations, but coordinated or not, national trade policies that are fundamentally designed to offset technological advances do not always advance the welfare of the entire population of those nations who have engaged in commercial trade.

Would it be heresy to suggest that most of the agricultural trade policies of the world are based upon an implicit assumption that suggests each nation will support a redundancy of resources in the agricultural sector by generating maintenance incomes for those resources through manipulated market mechanisms. In a static setting, this philosophy might prove desirable. It is both logical and natural to desire protection for agricultural incomes through trade restraints, if one assumes that low resource earnings are only temporary. But given dynamic conditions and some degree of resource fixity, the judgment of the market place concerning factor payments will not infallibly move an economy smoothly toward needed adjustments. Confronted with dynamics, at least two courses of action are possible:

(1) Establish trade restraints that to some degree negate the need for resource adjustment, or

(2) Use public monies exogenous to the market mechanism in an attempt to support resource earnings while adjustments in resource use are taking place.

The first strategy might be employed either when the situation is deemed static or when there is a reluctance to interface the agricultural and non-agricultural sectors of an economy. The second strategy might be desirable if low resource earnings were, in part, caused by dynamic conditions and the overall economic objective of the economy was to maximize aggregate welfare rather than that of an economic sub-sector.

We may be closer to general acceptance of the latter strategy than we might imagine. A Republican President has suggested direct supplementary payments for low income families. The stated objective of the President's policy was to maintain incomes outside the market place while human resource mobility was being increased through job retraining.

The current agricultural negotiation position of the United States might be capable of alteration if this nation adopted a meaningful program of sub-sector readjustment, implemented through enhanced labor mobility and achieved by way of large-scale retraining efforts supplemented by income assistance payments. Should the EFTA and EEC nations continue their policy of subsidizing agricultural exports, these products could be imported and used by the United States as complementary to the readjustment process. Still assuming a meaningful program on the part of our government to aid and speed inter-sector adjustments, our agricultural negotiators would then be less pressured to find foreign outlets for United States agricultural products.

I concur with the position that there is a natural tendency for each nation to attempt to countervail the actions of others when changes in trade barriers occur. In this case, however, we are encouraging subsidized agricultural exports by others so that we might receive an income transfer effect. It might be hypothesized that if other nations attempt to countervail this philosophy, the resulting mutual escalations would lead to a general lowering of the trade barrier profile.

The preceding may seem quite a fanciful treatment of the admittedly serious issue raised in the Malmgren-Schlechty paper—the steady increase in trade barriers. My remarks are intended to reflect upon the inherent conflict between problems caused by dynamic conditions and solution strategies based upon static doctrines.

Discussion: Policy and Non-Policy in Foreign Trade

G. A. MacEachern and B. Huff

The two papers are complementary. They focus on the essence of the problem—how to maintain the thrust and momentum of post-war policy leading to an increase in the international flow of goods, particularly agricultural products, within the framework of a reemerging feudalism.

Malmgren and Schlechty say international trading is bad now and is going to get worse. A new tool is needed to remedy the situation quickly. Schwenger has something substantial to offer but it may not be quick. Furthermore, changes will be required, especially on the part of negotiators, if negotiators are needed at all. Nevertheless, the suggestion deserves serious attention, early acceptance, and application.

There are a few comments one could make on specific points or degree of emphasis that reflect perspective from another trading country. However, the important point is the implications to agricultural economists and research of what is being suggested to improve agricultural trade.

Three major points are evident: (1) agriculture has been and will probably continue to be the most difficult stumbling block in efforts to liberalize international trade, so that any progress achieved will have externalities. (2) There are numerous inter- and intra-national problems associated with improved agricultural trade. Many are pervasive and outside agriculture per se. But there appears to be general agreement on the need for better information, more discussion, and new institutions concerned with trade. The Schwenger approach becomes more meaningful viewed from such an angle. (3) Our present state may be indicative of both the lack of intensity and irrelevance of research on agricultural trade problems or of the ineffectiveness of communicating known information to the public in general and particularly to those participating in international negotiation.

Schwenger's critical comments on trade theory appear to be more applicable to the negotiating aspect. This may be due to voids in research application, adaption to present realities, and the important trade questions, rather than to the relevance of the existing stock of trade and other economic principles. Trade theory has advanced considerably since the days of Smith and Ricardo. There are sophisticated theories and models that can handle dynamics, interdependence, space, and institutional restraints. However there are few examples where these have been used to provide

---

Gordon MacEachern *is president of the Agricultural Economics Research Council of Canada.* Bruce Huff *is assistant professor of agricultural economics, University of Guelph.*

meaningful tools to negotiators. At least commodity interrelationships can be handled conceptually and empirically. But commodity bargaining is still carried on as though separate islands exist.

The key to proper functioning of the International Trade Fact Authority proposed for better understanding and deliberations among governments and with the public is an improved research and information effort not only in the trade area but in domestic policy as well. Despite the availability of useful tools, there has been little application to the many important trade questions. For example, it is possible to construct global models although not incorporating all the complexities that may exist. These would be useful in analyzing the effects of trade policy changes. At least, commodity and area interrelationships can be specified to determine sensitivity to changes and direction of adjustments from trade and subsidy program alterations, without necessarily estimating the distribution of benefits and costs of the change. The converse to this has been the use of cruder estimates giving almost exclusive attention to producer interest, a need for greater experimentation, and perhaps reluctance to negotiate seriously. The minimum requirements for global trade improvements are far from being achieved. The limited attention given agricultural trade matters in research has largely focused on tariffs and, to a limited extent, on subsidies; although there are other equal or more important restraints, e.g., tax laws, patents, different legislation among countries, "multi-national" corporation trading and pricing policies, indirect tax systems, "restraint arrangements," etc.

Much needs to be done even though globally the matrices are large and befuddled and the estimates crude. Perhaps it follows that with smaller, more manageable matrices there would be better analysis and understanding of the impact from policy change. The open-deliberation concept as opposed to bargaining may have immediate application to smaller matrices, while new initiatives suggested by Schwenger are applied globally to obtain steady improvement. International wheat problems, the Common Agricultural Policy, global discussion of farm subsidy programs, and other key areas mentioned by Malmgren and Schlechty come to mind.

Does the knowledge limit on the effects of trade policy changes have anything to do with the growth of economic regionalism or custom unions? Would it make any sense (if we in North America are serious about expanding agricultural trade over the long pull) to demonstrate our sincere interest by seriously investigating the impact of removing at least some restrictions, moving toward a more compatible continental agricultural industry, demonstrating to others how this can be accomplished without damaging effects on other countries while pushing an open-deliberation policy globally. Even with GATT commitments there is plenty of leeway for improvements to be made.

Malmgren and Schlechty may be able to realize benefits quickly by applying the open-deliberation concept immediately on a variety of fronts and still exert global pressures while not having to wait for complete "degeographicalizing."

Would this be a more useful strategy in easing conflict and enhancing hopes for trade expansion? Would this make much more sense than stepping up cost pressures on other countries including the U.S. economy through subsidy retaliation now practiced and about to be intensified?

Discussion: Policy and Non-Policy in Foreign Trade

RICHARD J. GOODMAN

Both Schwenger and Malmgren tell us generally, in somewhat different ways, that the Kennedy Round was a failure. With that I agree. Malmgren is considerably more cautious in referring to the value of the outcome, and then clearly only with reference to agriculture. I have only a few remarks on his paper.

He tells us quite well, commodity by commodity, how bad agricultural trade protection has become, particularly in the EEC, but also in the United States, the United Kingdom, other Western Europe countries, Latin America, etc. He also fingers for us the particular vehicles upon which protectionism has been riding, e.g., the EEC's CAP, other minimum import pricing policies, import quotas to protect farm income schemes, and extra preferential trade arrangements. He then points out to us possible further problems arising out of additional economic regionalism and the international transmission of technology.

Malmgren comes finally to the resulting problems of international adjustment. But he discusses these problems in terms of quantities of commodities, mounting surpluses, and historically strange inter-commodity patterns of trade, observing that all of this costs a great deal of money, particularly in the EEC and, by almost offhanded incidence, that very high guaranteed and administered prices are of course involved. This is where frustration sets in.

The problem described stems, as Malmgren mentions, from resource misallocation. The absolute and relative levels of guaranteed and protected commodity prices directs the resource misallocation. These administered price levels are a result of income policies for agriculture that specify that prices be fixed to meet income goals within a given or assumed agricultural structure. So, what will be needed first of all, in Malm-

---

RICHARD J. GOODMAN *is vice-president of Cook Industries, Inc., Washington, D.C.*

gren's call for coordination of national agricultural adjustment policies, is a confrontation among agricultural trading nations over the future structual form and social significance of farming, at least in the industrialized world. After all, what is sought in coordination is harmonization. To harmonize policies of unstated long-run economic, social, or political objectives may not only be intellectually difficult, it might also be counterproductive to trade liberalization.

Schwenger's key points are (1) that the "free trade-versus-protection" concept of past GATT negotiations is obsolete and should be replaced by a "free trade-versus-economic fragmentation" concept; and (2) that the methodology of the traditional "round" of secret negotiations be converted into a continuous, fully public, multilateral deliberation. He contends that the present concept does not apply because it assumes isolated, static, laissez-faire national economies. All of this I believe I can agree with. However, he goes on to knock the single concept of free trade as "empty," "incomplete," and "defined only in terms of something not done." Free trade is used as the leading edge in identifying the obsolete concept (free trade-versus-protection), but it is also used as the leading edge in identifying the proposed new concept (free trade-versus-economic fragmentation). I have had to assume that what Schwenger has in mind, in a theoretical sense, is that the single concept of free trade is useful only when accompanied by a realistic view of the economic world as integrated, interdependent, dynamic, growing, and governmentally administered.

Running in this sort of company, the single concept of free trade is not empty, can be complete, and may be defined in things to do, that is, of positive rather than negative meaning. If this is an accurate interpretation of Schwenger's conceptual layout, it is fine. Where does he then lead us? He makes a point about traditional trade bargaining under the old concept that I suspect few people have come to fully appreciate. It is that at least the last two GATT "rounds" have increased trade barriers rather than decreased them. This has come about through the replacement of regular tariffs, reduced in the bargaining process, by non-tariff barriers not included in the bargaining process. The tariffs that were reduced had been substantially less trade restrictive even before they were reduced than the quotas, taxes, variable levies, and trading preferences that were added. So, I agree with Schwenger's point that trade policy concepts and negotiating methods of recent use have not worked. Of course, some new approach must be sought.

Schwenger suggests a new policy concept, which he finally describes as collective responsibility, defined as not precluding government intervention, not even for protective purposes, but only precluding intervention "applied along arbitrary geographic lines." Freedom of movement of trade, of course, completely precludes certain types of protection, and partially so others. But, the important and more interesting suggestions he makes are not conceptual, no matter how vague or high flying one might like such suggestions to be. Rather, it is his suggestions on method that have more immediate relevance. Open continuous deliberation supported and disciplined by full, clear, honest, independent information has obvious great appeal. It should have a better chance of working productively than any modified continuation of the old "round" method. One of the benefits could be the exposure of personal political interests, self-seeking prestigious aggrandizement, and paranoic personality problems among members, including leaders of national trade delegations. It could also be virtually the only way to bring about the productive confrontation of long-run economic, social, and political objectives for farming among the agricultural trading countries that I mentioned in connection with Malmgren's paper as being of beginning necessity in tackling growing agricultural trade protectionism.

CONTENT AND TECHNIQUE IN EDUCATION ON POLICY

CHAIRMAN: J. CARROLL BOTTUM, PURDUE UNIVERSITY

A Basic Framework for Policy Education

J. B. KOHLMEYER

THIS paper was prepared for educators primarily concerned with the development of an informal adult educational program in public policy.

The framework is designed from an educational operations point of view: What do you teach, who do you teach, how do you teach, and how well do you teach? I have tried to erect a sort of categorical scaffolding that makes it easier to pinpoint some of the elements that might well be included. I have tried to put these into nice, neat, little boxes. In actual practice, things are not that simple.

The framework submitted for your consideration, should be looked upon as an alternative framework. You well know that an educator tends to employ methods that fit his endowments. This framework reflects my observations and experiences over a period of years. The biases and prejudices that have crept in are those of an educator who has enjoyed operating in the public policy making arena for a number of years.

A Suggested Categorical Framework

1. *Specialize in an area. Then zero in on a problem that is identifiable; one that is small enough to be manageable; one that the public is going to do something about in the not too distant future. This problem may be of local, state, regional, national, or international concern.*

Timing is extremely important. Leftover Christmas trees are hard to sell on the 26th day of December. Straw hats do not adorn the haberdasher's shelves in December. Remember, when it comes to informal adult education, participation is voluntary. You simply cannot do any educating without pupils.

How can you tell what is going to be timely? How do you know what problems are going to be a matter of public concern? There are many different ways of course; I will direct your attention to only two:

(a) Keep your eyes and ears open. A policy educator must of necessity have a high listening I.Q. Travel, move around, read, talk to people. As

---

J. B. KOHLMEYER *is emeritus professor of agricultural economics at Purdue University.*

you travel throughout the state pick up local newspapers. Ask your country agents what problems appear to be a matter of public concern to the local leaders of his county. Live in the world of reality; know what is going on. Find out what's on your barber's mind.

Why do so many people ask what is Secretary of Agriculture Hardin going to do? Why did President Nixon propose a revamping of the welfare program?

(b) Apply outlook. Changing conditions give rise to problems. By 1949, it was obvious that school district reorganization would soon be imminent in the midwest. The mechanization of agriculture, which led to a decline in the rural population, indicated something would have to be done to get kids together in bigger bunches in the not too distant future.

By September of 1968 it was obvious that many of the elementary and secondary schools of Indiana would not be able to operate by 1970 unless the 1969 General Assembly revamped the method of financing. It did.

Well, if an educator has to keep up with what is going on as well as what is likely to be of concern in a year or so, he is forced to specialize in certain problem areas.

How many of you can tell me when the first crop of colts sired by either Bret Hanover or Noble Victory will be offered for sale?

Did you ever go to the grocery store and find out after you got there that your wife had forgotten to give you the list. The only place you could find anything with the label groceries on it was a sign on the wall. If you wanted to buy anything, it was a matter of salt, pepper, vinegar, etc. So it is with public problems. There is no such thing as the Health Problem, the Farm Problem, or the School Problem. Instead, there is a whole series of little problems. A little problem like what ought to be done about the trash and garbage that is being dumped in the alleys and scattered along the country side? If you want to know where to take hold, all you have to do is decide how you are going to collect it; how you are going to dispose of it, and how you are going to finance the job. From a problem-solving standpoint, we complicate things by putting cancer research and vaccinating dogs for rabies in the same package.

Instead of the School Problem, we find myriad little problems, ranging all the way from how money ought to be raised to pay teachers to how Johnny ought to cut his hair.

Here again, as a problem solver, you complicate things by putting them into the same package.

2. *"Tool Up." Get ready to do some informal adult teaching. Become an expert as far as a particular problem is concerned. Learn to know something about the individuals you are going to teach, their knowledge of the problem, their values, etc. "Be creative," invent some new solutions. Put the problem in a decision-making framework.*

In this endeavor your economic training will serve you well. But you will find it to be inadequate in and by itself. When you work on a public policy problem, you will find there are no purely economic problems. There are only problems with economic aspects. You will have to know something about the other aspects to fit the economics into its proper perspective. So with economic knowledge alone, you are in about the same position as a fisherman with a pole, but no hook or line.

Let me illustrate by relating one of my early experiences.

Years ago, one of our top county agents asked me to come to his county to discuss School Problems, and what the people could do to improve their schools. I assembled a lot of data, which was presented in standard extension specialist style. During the question and answer period, I was unable to answer many of the questions asked. The next morning, while we were having breakfast together, the county agent lowered the boom. His comment:

"Mostly bones, very little meat; you did a wonderful job describing the present situation and explaining Chapter 123, Acts of 1947. That information about enrollments, per capita costs, pupil-teacher ratios, etc., was interesting, but at this stage of the game it was not relevant. And as far as that Chapter 123, Acts of 1947, was concerned, they didn't care whether it was Chapter 123, 223, or 333, or whether it was passed in 1937 or 1947. What they wanted to know was whether to put 2, 3, 4, or 5 high schools together and the advantages and disadvantages of so doing. What they want for their high school pupils is four years of math, four years of English, four years of science, etc. They want their youngsters to be able to compete. How big does a school have to be to provide it? Now, when you get that kind of information together, let me know, and I'll see if I can get that bunch together again."

You see, my trouble was that I didn't know enough about schools. At that time most of the secondary information available about our elementary and secondary schools was interesting but not relevant for the problem at hand. Well, I never got caught with my pants down on that question again, but it took a while to dig up the answer. He never did get that bunch together again. Time and time again you never get a second chance. You know, there is such a thing as a teachable moment.

As you seek solutions for problems, you will find on numerous occasions that the means for accomplishing certain ends are inadequate, too complicated or cumbersome, and someone has to come up with an entirely new idea—an invention, if you please. Just as inventions supply the wares of economic change, so must inventions supply the wares of social change. Inventions advance the state of the arts, make new technology possible, and provide the individual and our society with a new range of choices.

Another thing that has impressed me over the years is *how little infor-*

mation is needed if it is the right kind and how much that I thought would be important is of little concern. You need to know what a lot of people regard as gospel truth, but "ain't so," and then set up a learning situation that enables the learner to discover it on his own.

After all, what you are trying to do is to provide the learner with an experience that will broaden his knowledge and understanding about the problem—the choices available to him, the probable consequences of each choice—thereby providing him with a broader basis for decision making. You can't make policy without making some decisions.

3. *Make plans to provide a learning experience for individuals vitally interested in finding an acceptable solution for a particular problem.*

As the Extension Service, of which we are a part, is organized, it is difficult to operate without a booking agent. It is at the local level that decisions are made about what is to be taught, who is to teach it, and who is to be taught.

The provision of a staisfactory learning experience takes a lot of preplanning. Actually, if well done, this is a joint undertaking of area administrators, local agents, and the specialist.

For illustration purposes, I would like to recite a recent experience. Earlier in the paper, mention was made of an impending school finance problem. There was wide-spread confusion about the present situation and probable future developments, as well as about what might be done. The likely governor-elect was running on a no-new-state-tax program. Local school districts were confronted with local tax rate limitations. The General Assembly would convene in early January 1969.

The desirability of providing a learning experience in this problem area was first discussed with the area administrators. They were aware of the fact that this problem was a matter of public concern, and they put consideration of the problem on a high priority list. Next, how do we get in gear? After we had given consideration to preferable dates, how to secure attendance, who was to be invited, kinds of subject matter material to be offered, etc., the area administrators agreed to take over, provided I would prepare a memo to be sent to each agent. It was tentatively decided to have a dinner meeting in each area, shoot for an attendance of 75 to 100, get acquainted 5:30 to 6:00, dinner 6:00 to 7:00, adjournment by 9:00 p.m. Why dinner meetings? It is easier to get attendance.

In a week or so the phones began to ring; some of the area agents insisted that they needed to have more firsthand information about what we expected to accomplish, etc.

Five or six conferences were arranged. Calendars of agents and area administrators were too cluttered to arrange them in all areas. (Fortunately, this gave us some check plots.) One of the first questions raised by the agents: If we make reservations for 100 and only 50 show up, who picks up the tab? We discussed at considerable length just who was to be invited. Believe it or not, each county was given a quota (example: 8–12); no open invitations; tickets were to be sold in advance. On the whole, this intensive pre-planning paid off. A typical cross section attendance consisted of:

20–25	school board members—not more than 2 or 3 from each school district
20–25	business and professional people
15–20	farmers
2–5	legislators
15–25	other

We hoped to be able to attract individuals who were concerned with finding a satisfactory solution for the problem and who, once having decided what ought to be done, knew what steps to take to get it done.

You might be interested in knowing the comments of the legislators. In substance they were about like this: "Unusual experience to be invited to a meeting where someone didn't try to brain-wash you." "If more meetings like this were held over the state, the life of a legislator would be easier."

Newspaper men are still trying to find out what that expert from Purdue University really thought ought to be done.

4. *Provide a satisfactory learning experience for the individuals participating in this particular activity.*

The individuals you expect to attract to your meeting, conference, seminar, or whatever you choose to call it, are busy; their time is valuable. If they do not have a satisfactory learning experience, the news will travel. The next morning, if not yet that night, everyone in attendance will be asked by one of his peers, what went on last night, did you learn anything or was it a waste of time, etc. If they reply, "I wouldn't have missed it for anything, you should have been there, I learned a few things I never knew before," you are in business. But if they say, "I wish I had stayed at home," you are in trouble. If you do a good job, your booking agents will perk up, and you are on the road to developing a clientele, for public policy education, for the Extension Service, for your university, and, last but not least, for yourself.

Years ago, one of my teachers once commented, "Subject matter without method can be boring, method without subject matter content is sterile." Now what are some of the things that you need to do? This may be the first time this particular group has ever been together. They are a diverse lot; things are tense. It's not like the meeting where everyone there was a banker or a Ford dealer or a Farm Bureau member, or an Elk.

Well, you need an ice-breaker of some kind, an attention getter. A disarming device. Make everyone feel welcome and at home, and let him know that policy education is different. Stimulate discussion, cast yourself in the role of a discussion leader and wipe out that college professor image, watch your vocabulary, get to the crucial points fast. Bore in on the one, two, or three "key points." Substitute facts for what they think are facts but are not.

In those school finance meetings I placed high on the agenda, "Dispel some misconception of 25 years standing about the consequences of low and high qualifying rates and low and high foundation programs."

Qualifying rate is a legal term which established the minimum local tax rate that must be levied to be eligible for state aid. Foundation program is another legal term, similar to what farmers call support prices. In other words, the state says we will support your school costs up to X dollars per pupil and pay you the difference between the support price and the amount raised by the qualifying rate.

Well, every text book I have ever seen on school finance says the qualifying rate should be low enough to give the local school district enough elbow room so that they can levy a tax higher than the qualifying rate. What the authors forgot to say was that additional elbow room in a peach tree with no peaches on it simply won't put any more peaches in the basket. School administration in school districts with very little wealth per pupil have fought for years to keep the qualifying rate low.

All we did was set up a sixth grade arithmetic problem and worked it out together on the blackboard to see how it came out.

A low qualifying rate in itself makes poor people poorer. It permits the wealthy to get under the state aid umbrella, which means that you run out of money in a hurry.

I have yet to find an occasion where the application of sixth grade arithmetic wasn't all the math you needed. The Russians say all you need to know is to be able to multiply and divide by 2. You do not need to know anything about fractions.

Get down to alternative solutions and consequences in a hurry because that is the "meat." Then give them a chance to exchange ideas with each other. You know this is fun—involvement learning something you didn't know before, getting the cobwebs out of your brain, without being told you were dumb, etc.

5. *Be willing to provide technical assistance when needed.*

Making a decision about what ought to be done is just one step in the policy-making process. The next step is putting legs on the decision.

Often this will require a new law, or an amendment to an existing law, or the preparation of an ordinance or the like.

Sometimes they need help, and you may be able to tell them where to get it or you may do it yourself. I have either written or helped write over 50 bills that have been introduced to the General Assembly. A lawyer can't do it alone; before he can write, he must know precisely what you want to accomplish and what procedural steps you would like to follow to do it.

6. *Give your clientele an opportunity to tell you what they think of it. Ask them to grade the teacher.*

Our former Dean and Director, H. J. Reed, used to tell his extension workers:

"Extension teaching and college class room teaching are different. Here at the university, the professor flunks the pupils; in Extension the pupils flunk the teacher."

All of us have seen rating scales. I remember one I once filled out at one of our neighboring midwest institutions; on reverse side of the sheet, I wrote something like this: "On your rating sheet, you failed to ask the right questions; you should have left a place for remarks. My remarks are as follows: Unless the kind of learning experience you provide is radically revised next year, I am going to advise every individual in the United States I know who might attend to stay home." It was radically revised.

I have not developed a rating sheet; but, now that I have retired, I am working on one. I need help. As a starting point, the one used by G. H. Wheatley at the National Science Foundation Summer Institute at Purdue University includes some criteria that might be helpful. Without too much trouble, we can make some appropriate deletions and/or additions.

Let me read some of it to you.

Course and Instructor Rating Form

On the following pages you will find a list describing various characteristics of college instructors. Please rate the primary instructor (lecturer) of the class in which you received this questionnaire on each of these characteristics. Using the scale shown below, write the number corresponding to your answer in the space provided to the right of each question. (i.e., you are to answer on the questionnaire itself)

1 ________	2 ________	3 ________	4 ________	5 ________	6 ________	7 ________
completely unsatisfactory	poor	adequate	good	very good	superior	Na (not applicable)

IMPORTANT!

You may remove this instruction sheet for easy reference to the scale. DO NOT detach any of the other pages. PLEASE!

1. Formal or textbook knowledge of the subject matter ______
2. Personal knowledge or experience with subject matter as demonstrated in lectures, labs, etc. ______
3. *Ability* to answer students' questions about the subject matter satisfactorily ______
4. "Up-to-date-ness" of the material presented ______
5. Interest and enthusiasm for the subject matter ______
6. Is concise in his presentation (does not use too many words or repeat unnecessarily) ______
7. Adapts to the class' level of vocabulary and understanding ______
8. Presents his ideas clearly (unambiguously) ______
9. Gets his material across to the students (communicates his knowledge) ______
10. Generally makes a subject seem interesting to the student (entertaining) ______
11. Stimulates interest in a topic (makes students want to study and learn more about it) ______
12. Challenges the students to think and work things out for themselves ______
13. Loud and distinct speaking voice ______
14. Appropriate rate of speaking—not too fast or too slow ______
15. Legible blackboard writing or printing ______
16. Makes expectations about performance and policies (grades, attendance, etc.) known early in the term ______
17. Is punctual beginning and ending class ______
18. Keeps class under control (doesn't let a few individuals dominate discussions, etc.) ______
19. Is concerned that his students grasp the material presented ______
20. Properly assesses the amount of outside work (homework) appropriate to the course ______
21. Makes homework a useful experience ______
22. *Willingness* to consider questions from students ______
23. Encourages class participation through the maintenance of a suitable informal atmosphere ______
24. Willing to listen to divergent or opposing contradictory ideas or viewpoints (is open-minded) ______
25. Accepts criticism or suggestions from the students ______
26. Willing to admit mistakes or lack of knowledge ______
27. Willing to help individual students outside of class ______
28. Shows interest in students as people (knows names, etc.) ______
29. Respects students knowledge and opinions ______
30. Treats all students fairly and equitably ______
31. Sense of humor ______
32. Self-confidence ______
33. Taking everything into account, I consider this instructor ______
34. Taking everything into account, I consider this course ______

Discussion: A Basic Framework for Policy Education

WALLACE BARR

In his humorous, illustrative, and unique manner, Kohlmeyer has given us some of the generally accepted practices and some techniques used in most successful extension policy education programs. His suggestions: (1) specialize, (2) develop a high degree of competence, (3) provide a decision-making framework, (4) pre-plan with local and area personnel, and (5) provide technical assistance as needed. The best evaluation in extension that I know is, "Do you get the second and third invitation?"

His expertise is greatly enhanced by his ability to communicate with people. His "homespun philosophy," vast experience, and well selected illustrations provide him an almost instant audience rapport. Most of us do not have this ability. Each of us needs to develop his own personal techniques to gain audience confidence.

My own conception of the basic framework for policy education was merely alluded to in the presentation. As I view the policy framework, it involves taking people through the process of (1) developing a common understanding of the situation, (2) defining the issues, (3) identifying the alternatives, and (4) determining some of the consequences of various solutions. Each person then determines for himself, within his value system, his choice of alternatives. The principles and techniques of operation developed are used in planning, implementing, conducting, and evaluating the program.

A Policy Program

A fundamental objective of policy education is to provide the basis for people to take more intelligent action through proper channels—whether in the ballot box, through organizations, or with legislators. This implies a policy education program on a major problem area. A policy education program needs to reach (1) the masses, (2) local community leaders, and (3) leaders of special interest groups. A balanced effort directed toward these audiences, conducted by competent staff utilizing the policy framework and properly implemented, should result in an effective policy education program.

Mass media efforts are important to create awareness and are an important part of a total educational program in policy, but alone are insufficient. Working with the leadership of special interest groups at the area, regional, or state level is an integral part of an educational program in

WALLACE BARR *is with the Ohio State University.*

policy. These are the key people who "get things done" within the political power structure. Influential leaders at the local and area level are very important in the group decision-making process who I fear are too often overlooked in extension policy education programs.

We in Ohio have moved in the direction of intensive and in-depth training for selected local leaders in two major policy problem areas. Our successful community development program involves about 12 hours of intensive study of local community problems as identified by a local planning committee. The enrollment consists of selected people who can influence future community decisions and help determine future directions.

Food and Fiber Marketing Policy Seminar

To provide a setting and climate for discussion of some of the economic, political, and social factors involved in our marketing system, we are conducting food and fiber marketing policy seminars. Broad objective of the seminar is to develop in individuals the understandings needed to make decisions concerning the market system and institutions. The seminar consists of "core" and "optional" subject matter; its program is highly flexible, open ended, and requires intensive local planning by a selected group of six to twelve leaders representing the farming and agribusiness interests of a two- or three-county area.

The general format calls for three all-day sessions, usually a week apart, providing 15 hours of instructional and discussion time. The seminar audience is limited to 40 to 60 people who are carefully selected as representative local leaders. Each pays a fee of $10 to $15 to cover the cost of materials, room rent, fees of selected speaker, and luncheons.

The core subject matter deals with the structure of farming and the marketing system, price determination, and social and economic values. Five hours of instructional and discussion time are allocated to these areas.

The optional topic areas chosen by the local committee may include bargaining, foreign trade, land retirement, market orders, promotion and advertising, low income farm policies, reducing price risks, inflation, politics of agriculture, or any other subject matter felt to be appropriate by the local planning committee. The broad subject matter areas are subdivided into manageable units and given popular titles.

A typical food and fiber marketing policy seminar contains three or four of the optional subject matter topics. Usually four to six different departmental staff members are on each seminar program, although some seminars require "outside" personnel.

This approach provides a sound educational environment in which people can explore in some depth and within an analytical framework. The various alternatives are evaluated, considering peoples' values and in view of the expected economic, social, and political consequences.

The process, though slow and unsensational, is nevertheless effective if extension agent, participant, and administrative opinion are valid criteria. This approach has paid large dividends in public understanding of numerous marketing policy issues. The in-depth policy programs (community development and marketing policy) have enhanced the image of the cooperative extension service and the university with traditional audiences. They have attracted many new supporters.

Discussion: A Basic Framework for Policy Education

W. FRED WOODS

Whether or not the true goal of agricultural economics is to be a handmaiden of policy [3], the extension policy specialist is more or less intimately involved in the area. The explosion of change—technological, social, institutional—has expanded the need for policy education.

In our society the collective citizenry presumably make the important decisions. They vote their convictions, elect candidates who express certain views, and exercise collective and individual voice through various pressure forms. The continued success of our, or any, free economic and political system depends upon informed citizens who exercise their right (perhaps we should say, their responsibility). These statements have always been true, may even sound trite, but they take on a more important meaning today.

Extension has had public policy, or public affairs education programs, at least on paper, for many years. But there has been considerable more talk than action in this area. Ratchford, in 1963, observed, "There are very few examples of truly outstanding public affairs programs of sufficient depth and scope that decisions on public issues have actually been influenced" [4]. In 1969, with the exception of a few states, I see the situation largely unchanged.

Professor Kohlmeyer and his state are among the notable exceptions. Writing as he does from an established base of operation, his words are given added authority. The foregoing notwithstanding, there is little room for disagreement with Kohlmeyer's paper. The only possible reservation I have is this one: J. B. Kohlmeyer can operate in this manner. Could I?

A successful policy educational program involves, first of all, an important administrative decision. Meaningful educational programs in this area cannot be conducted without encountering controversy. The very essence of public policy problems suggests conflict, compromise, and consent [1].

W. FRED WOODS *is with Auburn University.*

Public policy issues are often characterized by strong vested interests. These interests want either one of two actions from the Extension Service: (1) they want Extension to advocate particular policy positions, or (2) they want to prohibit Extension from operating at all in the area of public policy.

There is a wealth of material available on most public issues but much or most of it is necessarily biased to reflect the views of the organization, private or public, that puts it out. There is a great need for some organization to do a thorough and unbiased educational job on public issues. Who is at least theoretically better equipped to do this job than the Cooperative Extension Service? Therein lies the administrative decision. To meet an obligation or to ignore it—that is the question.

Once the decision has been made to conduct an educational program in the policy area, we are ready for Mr. Kohlmeyer. Policy education is truly different from other extension educational efforts. Where most extension specialists give specific recommendations, the policy specialist must deal with a range of alternatives and their consequences. To me an analagous situation would compare the mechanic who works on the car with the engineer who designed it.

Whether the policy specialist deals with already known alternatives or does the inventing to afford new choices that Kohlmeyer calls for, the potential rewards are great—an enlightened population and a stronger nation.

The future of Extension may well be in this area. In a satirical approach, Professor Cyril O. Houle of the University of Chicago related the story of how the Extension arm of a mythical land-grant university finally broke with tradition and entered into a program of public affairs education [2]. As Houle relates, "A surprising thing happened to the Cooperative Extension Service. As soon as it stopped thinking about its glorious past, it turned out to have a glorious future."

AGRICULTURE AND THE LAW

CHAIRMAN: W. B. SUNDQUIST, ECONOMIC RESEARCH SERVICE, USDA

Institutions and Instruments—Management Alternatives

N. G. P. KRAUSZ AND F. J. REISS

INSTITUTIONS, and their accouterments of laws and legal instruments, develop from man's responses to his needs in relation to other men. However, once established through usage and general acceptance, institutions tend to govern and determine behavior rather than be a product thereof. Laws, conventions, institutions, legal instruments—all tend to effect a conformity in the individual's behavior and response to social and economic situations. In a stable society, such conformity in behavior may contribute much toward a smoothly functioning and peaceful existence. It does not, however, result in progress, unless progress is defined as extending the status quo.

From simple curiosity and observation to highly organized research, and from direct conversation to sophisticated satellite communication and formalized instruction, man's knowledge horizons are rapidly expanding and intruding upon the status quo. Inevitably, institutions, laws, and their accompaniments are confronted with a changing environment. Agriculture has not been untouched by problems of change.

It is not our purpose to elaborate and document the changes that have brought us to our point of concern, but it will be useful to recognize some of the dynamic aspects of the agricultural economy as a background for our discussion. Among these are the following:

(1) Farms are growing larger, more highly mechanized, and more specialized in their production.
(2) Substitution of capital for labor, largely a matter of mechanization and automation, greatly increases the amount of capital associated with one man's labor.
(3) Farm production is highly market oriented, which makes farmers sensitive to price changes and creates a demand for greater producer control over marketing and price-determining processes.
(4) Inputs generated within the farm firm have almost disappeared.
(5) Management in the organization and operation of farm firms is more critical to success and survival than ever before.

N. G. P. KRAUSZ *and* F. J. REISS *are professors of agricultural law and farm management and land tenure at the University of Illinois.*

All of these developments create and present problems legal and institutional in nature. Traditional and established practices and procedures may now be impediments. Instead of playing a facilitating role, institutions and customs may inhibit desired changes in the following ways:

(1) They affect and limit the allocation of resources, among uses and users.
(2) They may restrict use of resources to less than optimum amounts because of uncertainties in the rights of possession and use.
(3) They may create or contribute to dissociations between ownership of inputs and claims upon returns.
(4) They may contribute to inefficient use of resources.

In these and other ways, established and institutionalized arrangements may actually impede economic progress. There is another side to the coin, however. The borrower needs someone who would be a lender. The tenant needs a landlord. And the specialized manager of a farm business must find an employer, a man (or men) with land and capital resources. Their needs, too, must be considered.

A key concept in considering legal instruments and institutions is the individual as a responsible agent, responsible for the management and use of resources, accountable for infringement upon the rights of others, obligated to perform as required under contracts, expected to make payments for goods and services received, obliged to repay borrowed capital, and liable for the consequences of forces set in motion and actions initiated by him. This person economists have identified as the entrepreneur and have recognized his contributions, through his decision making and accountability, to the productive process.

The instruments and institutions that spell out and document the entrepreneur's rights and responsibilities are a product of the prevailing technology as well as of the structure of society. Thus, a high degree of personal responsibility was appropriate to small family-operated farms organized as single proprietorships—but is such responsibility equally appropriate to productive organizations whose assets may greatly exceed the net worth and financial accountability of the individual entrepreneur?

Our answer, of course, is negative. Society has long used legal and institutional devices to relieve the farm operator of a large share of such burdens. Farmers rent land and borrow money. They contract for supplies and for the delivery of products. They hire labor and services. But the growing dimensions of the typical farm firm, the increased functional specialization, and other consequences of technological changes leave at least some of these arrangements quite inadequate and/or inappropriate.

This is the context in which we shall look at our current inventory of devices employed in the past and some emerging in the future.

Economic—Legal Issues

In studying relationships between economics and law, it is useful to examine some conceptual differences between the two fields. Economics is the discovery of rules and principles and their application to a working situation. Law is the attempt to create rules for an orderly society. For example, economists consider land as a natural resource and buildings as capital; therefore, as separate components. Lawyers consider land and buildings together as "real estate." As real estate, it makes the establishment and recording of ownership easier, simplifies the distinction from personal property, and facilitates the transfer of title from one owner to another.

Some legal rules are more flexible than others. Contract theory has allowed wide innovation in the structuring of economic component relationships. However, agricultural institutions and customs, such as the share lease and the family farm, have limited the opportunity for new organizational forms and specialized relationships to develop in agriculture. Relationships by "custom" do not always act fairly in allocating control, risk, and return to the participants.

In contract problems the parties themselves and the courts can overcome inequities; but in the case of established institutions, questions of policy are raised and thus state and federal executive and legislative bodies may be involved. Law and legal institutions being of political origin, the question of changing established arrangements is in fact a political one. Because great numbers of various types of people are involved, it is also a social problem. Legal institutions and their consequences are the result of political attempts to solve economic and social problems. In analyzing the agricultural legal structure, consideration must be given to social and economic reasons for the particular way in which it has developed and the impact of changes upon society.

The basis of current U. S. agricultural structure is the small owner-operator theory of early land distribution laws. Agencies such as the Extension Service have perpetuated the family farm type operation by providing information, research, and other services which individual operators of this size could not alone afford. Government farm programs also have encouraged the continuance of this type of operation by assisting farmers financially so they can remain in farming.

Laws have influenced agricultural structuring through their effect on the land-people relationship. In the past, the ownership of land was the key. But rights in land, though often more formal, are actually less absolute than rights in personal property; that is, they are more subject to split ownership or to restriction on their use. For example: (1) Leases represent a temporal interest in land, a means of allocating the income from land, and a means of controlling land use via covenants and other provisions; (2) Tenancy in common permits undivided co-ownerships in land; (3) Joint tenancy limits transfer alternatives through its right of survivorship provision; (4) Life estates are only a beneficial interest in land, but with elements of trusteeship; (5) Easements constitute a restriction on a servient tenement and an asset to a dominant tenement; (6) Police power through zoning regulations can restrict freedom of use; (7) Nuisance laws impose similar restraints on freedom of use; (8) Eminent domain affirms the superior right of society to the use of privately held land; (9) Adverse use is a socially derived principle against perpetual neglect or non-use of privately owned land; (10) Statutes of limitations cut off title interests when abandoned or carelessly guarded; (11) Land registration is an ownership defense not required of personal property.

In the area of contract law, most restraints are non-legal except as the relationship intended establishes one of the durable institutions. Probably the most severe restraint is the impact of taxes. Otherwise, the contract is a malleable instrument receptive of the wildest dreams or the indurate agreement of callous businessmen.

Statutory and case law provide stability, and this must be so for faith in future application. Legal precedent is the bulwark for contract, investment, and ownership. However, this also explains the tardiness of law. Law follows economic and social needs and pressures—it rarely leads. A most pressing case must be made for any change in legal institutions.

Fee Simple Concept

The historical base for land law is the fee simple concept—in theory allowing maximum utility and minimum interference. Also, the ultimate in privilege—to be allowed to transfer all title rights to beloved or friend at death or inter vivos [1].

The liabilities of fee ownership have grown immensely—liablity for tort, for nuisance, for taxes, for maintenance. Restrictions have multiplied—zoning controls, land use plans, special districts forcing in the minority, elimination of access, public easements, cropping limitations, statutes of limitations, pollution controls, labor rights, and so on. The quantum of the fee simple concept has indeed been eroded.

Fee simple ownership has become less important concomitantly with a decreasing voice in the use of land. As land prices increase and returns on investment decrease, operations with owner-operator-control splits will increase. As vertical integration shifts more and more functions off the farm, it becomes less vital that the operator own the land and other assets he operates. Land pool companies and futuristic securities market in land further widen the fee simple owner-control split.

The right to divide the fee into parts, equal and unequal, also is of ancient derivation. It is miraculous that our laws of descent have not caused the same disastrous physical splintering as in Europe. Joint and fractionated ownership have caused management problems in the United States but have not prevented the enlargement of farm units. Shared ownership may now be considered an economic blessing because of high capital inputs.

Possession Separated

Tenancy is one of the oldest institutions for separating the function of ownership from those of possession and use. In spite of its age, farm tenency is an extremely important tenure institution today. This is especially true where land values are high and among young farm operators. The dissociation of title and possession obviously must be allowed by law. Tenancy has lost its stigma, allows younger people to farm, particularly the higher priced lands, and also permits expansion by owners of undersized units. Without a strong tenancy system, the old and the misfit might be sowing our seeds.

Most of the recent growth in size of farm has occurred through renting of additional land. As a result, the typical operating unit [8], at least in the midwest, greatly exceeds the size of the average ownership unit. Many part-owners, as well as full tenants, are renting land from more than one owner. Some landlords have turned to "custom farming" arrangements in place of share-renting, while others are trying cash leases to increase their net return. Some tenants view cash leases as a means of competing more vigorously for land to enlarge their farms. Others see cash leases as a means of gaining greater managerial freedom and flexibility when renting a large acreage from a number of independent owners.

The institutional arrangements and the customs associated with share-renting are being challenged, and one can ask why. Why abandon the comfortable stability of the 50–50 crop-share lease that permitted, if not actually encouraged, much of the technological progress in raising American farm productivity to unequalled levels? Landlords have answered that they need more rent or that they want to be relieved of the burdens of management incumbent upon a share-rent owner. Tenants have admitted to competitive bidding for land and to a desire for greater managerial freedom.

Fundamentally, these and many other responses, are an expression of three major problems in determining the structure of farm firms: (1) How can an adequate quantity of resources be obtained by a prospective farm operator to create a firm that can operate efficiently? (2) How much are individual factors of production worth? (3) What arrangements can provide the desired assurances of possession, tenure, and managerial control?

The first problem area is part of the overall question of allocating scarce means of production among alternative uses. Specifically, the creation of a farm business assumes the presence of a responsible personal entity, typically an individual entrepreneur, who will make commitments to pay for the use of resources owned by others and/or accumulated through personal saving. These commitments are evidenced by such documents as leases, mortgages, deeds, and contracts. It is here that convention and custom exert their influence in hindering or facilitating the creation of adequate farm firms.

The second problem area, that of valuing individual inputs or factors of production is, in theory, a problem of determining or approximating marginal value products. Just how much is land worth? How much annual net rent can a farm operator afford to pay for an acre of land? How much net income will be generated by adding a second or third tractor, or a hired man, or an employee who assumes managerial responsibilities? Few farm operators have good answers to these questions. They accept market prices as uncontrollable variables, and decisions to buy or invest are not infrequently made on the basis of ability to pay rather than on an expected return ratio.

Economists have attempted to answer such questions academically with the aid of costly statistics and costlier equipment [11]; but farm operators, less well fortified, must answer such questions in terms of personal commitments. It is small wonder that they hesitate to deviate from customary arrangements, because these arrangements may constitute the only expression of a market price for the services of such unpaid inputs as land and entrepreneurial labor.

Share leases tend to avoid the problem by becoming quasi-partnerships with the landowner sharing in production and price risks and in a variety of costs [9]. The economic rent for land is disguised behind a number of associated non-land inputs. As a result, there is a reluctance to deviate from established practice; and questions of adopting new inputs such as new methods of crop harvesting, conditioning and storage, or herbicides as partial substitutes for mechanical weed control, become involved in the land rental problem.

In theory, cash leases should solve these cost-sharing problems, and indeed they do, but then the problem of approximating the annual worth of land stands in bold relief. When problems of risk and greater capital requirements for the operator are considered, the net gain may be questionable. In a dynamic and variable economic environment cash leases have problems of their own. For example, assume that one starts with a fair and equitable gross cash rental; will this rental be fair and equitable for the next year, or the one after that [7]? Are we not putting rent determination on bargaining strength rather than a land productivity basis? Or, given a highly competitive rental market, do we not increase tenure uncertainty if land control shifts capriciously to the highest bidder?

This brings us to the third problem area—what can be done? Much good work has already been accomplished in developing farm lease forms that remind their users to arrive at mutually satisfactory agreements on a number of potentially troublesome questions. Basic principles, such as sharing variable costs in the same proportion as returns, are well established but need to be taught to tenants and landlords [10]. But it is equally important to teach appropriate accounting and budgeting procedures, whereby farmers and landowners can do a better job of estimating changes in costs and returns from new practices, and how to use such information to make enlightened changes in farm leases or operating contracts [10]. Dependence on or retention of traditional institutional arrangements may render a questionable service to agriculture unless the capacity of entrepreneurship can be raised to modify such arrangements to accommmodate a changing technology.

The life estate institution, another separation of possession from title, has rigidities that seriously weaken its use if the public interest is considered. Remaindermen, even if mature and capable, are legally devoid of management, and have only the vague and disarming right to prevent waste. The life tenant is limited to land surface use, with no right of alienation and virtually no security for borrowing. Legal instruments can be used to vary this inflexible institution and the problem should be examined for greater elasticity. It is a gritty issue however, because of many vain males and a strong desire to protect children [5].

Title Divested

An area of intense legal study is the divestiture of title in exchange for intangible interests. The conversion is from real to personal property, which substantially affects the prestige of the security. Credit sources often require corporate owners to surety the very institution they created and which holds the title. This enigma could be eliminated by changing our security laws but it would be an admission that the conversion to intangibles was incomplete. If there is any fault, it probably lies in the weakness of an institution not so readily adaptable to the small firm. A mini-market for corporate shares also causes other problems such as locked-in shareholders and the use of book values for buy-outs [2].

However, the corporate institution is sufficiently viable and the supporting instruments amply flexible to allow a liberal supply of corporate advantages for the small firm. The fringe benefit package does not bristle with an opulent flow of gifts but many of the restraints on insurance, pensions, and stock transfers can be overcome by judicious drafting.

The management advantages are several if capital resources are adequate: (1) a complete separation of labor, management, and ownership is permitted; (2) the management contribution can be more readily ascertained and appropriately compensated; (3) management can be centralized, but additional voices can be allowed in policy making, (4) substantial ownership can be transferred without loss of control; and (5) top management is more apt to be retained as ownership changes.

Twenty Illinois farmers who recently incorporated on a family basis replied [6] that they had four primary objectives: (1) to maintain an adequate sized farming unit for the children; (2) to lower inheritance taxes and transfer costs; (3) to gradually shift ownership without losing control; and (4) to inspire interest and management participation by the children.

Other reasons given included: (1) to reduce the total income tax by adding another taxpayer (the corporation) and by creating additional deductions (e.g., depreciation of residences and medical and group life insurance); (2) to obtain fringe benefit advantages for the owners; (3) to limit liability; (4) to obtain purchasing discounts; and (5) to facilitate expansion of the business.

It is noteworthy that operational economic considerations are secondary and that the dominant motives related to intrageneration transfer, with a deep feeling of protection for the family. The corporation structure appeared to them to best meet their needs without immediately sacrificing serious loss of control and the security of an ownership interest in land.

It also is remarkable that 80 percent of these farmers, with assets averaging $400,000, incorporated only in the past six years. They have suffered from lack of knowledge about more sophisticated organizational methods plus the fact that existing legal institutions have fulfilled only a part of the needs of closely held businesses.

In states where permitted, the land trust is an excellent substitute for the corporation if estate planning is the dominant motive. However, in some cases it may afford another choice to horizontally integrate similar production units as a bargaining tool of small landholders against large operating corporations.

A few states have refused to label these trusts as "dry" and only a title holding function is allowed for the trustee. Management is retained by the beneficiaries who often designate one of their own as manager. Beneficiaries own personal property interests that are transferred much like a corporate share of stock. The instrument involved is an unrecorded agreement between grantor and trustee (sometimes the same person). This device allows low cost planning and distributions without partitioning the land and merits the attention of more states and more farm owners.

Title also may be held by a partnership and, with well drafted agreements and buy-outs, can simulate the corporation in many legal ways. The most severe legal blocks are unlimited liability and judicial dogma that a partner can only be an employer. The liability rule has little practical significance in the tort area of law, but it is relevant when fraud and unauthorized contracts are used [3].

The partner-employer rule disallows business deductions for fringe benefits they receive from the partnership. If partners could be employees as well as owners, a concept enjoyed by shareholders employed by their own corporation, the attractiveness of the partnership would be substantially enhanced. This possibility does exist for a limited partner, but it would be impractical to have limited partners in many situations.

In spite of some trepidation, farm corporations and partnerships are replacing a number of single proprietorships. They appear to have solved or avoided the three problem areas of acquisition, valuation, and control of resources; but this may be an illusion. Shares in the family farm may be locked-in, thus avoiding or minimizing acquisition costs for sizable land and capital inputs under a family corporation. However, they may also represent an alien, unfriendly, or uncooperative ownership interest. Furthermore, a fair and equitable distribution of earnings requires a working knowledge of marginal value products coinciding with the differentiated ownership or contribution of factors.

The corporation appears to be an ideal way (1) to relieve the manager-entrepreneur of the burden of furnishing or being responsible for all capital inputs and (2) to pool the equity resources of a number of people in achieving a desired scale of operation. The corporation, as a legal-personal entity, is capable of accommodating virtually all sizes of enterprises above certain minimums. It may be precisely this capacity for bigness that has brought the corporation in agriculture under criticism.

The family farm business is, by definition and otherwise, subject to effective restraints on its size. It has a characteristic of direct personal association between the owner-operator (and his family) and all or most aspects of the business. The corporation, on the other hand, may be impersonal in its human relationships through the specialized roles of its directors and employees. Inherent in these differences are the bases for value judgments concerning corporations in agriculture. The economist insists on a neutral position with respect to personal or social value judgments. They may be introduced into his analyses as parameters or as variables if they can be quantified, but the economist qua economist does not make value judgments. The corporation, on the other hand, is totally indifferent to value judgments. Hence, we have the question, as individuals, and as members of society, as to what, if any, restraints on size and growth, on scope and activities, and so on, we wish to place upon the legal-institutional arrangement known as a corporation.

Title Holding and Transfer Problems

A benevolent system of government allows private ownership of the surface and the subsurface, and the transfer of either or both during life or at death, in a variety of ways. At least 20 different estates and interests have been carved out of fee simple. We have so many interests, there is difficulty in keeping accurate public records because of marriages, death, divorces, descent laws, adverse possession, joint tenancy, wills, dower interest, insanity judgments, statute of limitations, contracts of sale, prescriptions, assessments, tax claims, mortgages, attachments, easements, leases, conditions, life estates, contingent interests, etc. One could in innocence ask what new is needed—what does the market require now? Has the law not already over-responded to economic and societal needs for different interests in real estate and for different kinds of institutional arrangements?

The answer, of course, is that title to any property is not held in isolation and must accommodate itself to new impingements of a society and government in flux. The impact of income and death taxes alone demand innovations for avoidance. The lack of farm estate management can strap succeeding generations with a debt structure that forces sales and strains credit sources for operating capital. The use of substantial gifts and life interests, often via the trust route, have captured the imagination of owners and attorneys in the past two decades.

A title transferring arrangement of increasing popularity is the installment land contract [4]. With low equity, it is a financially painful way to climb the agricultural ladder, but it does put land resources at the disposal of an operator not endowed with generous amounts of equity capital. Within families such sales are most appropriate for the buyer if combined with other land transfers on a gift basis or the periodic cancellation of a portion of the installment payments [4].

For the seller, installment contracts have more to offer. The income tax generally is less; steady annual payments can be relied on for retirement purposes; the income is not subject to social security tax, nor does it reduce benefit payments; the security still is the land; the price is pegged for death taxes; and management responsibility is transferred to the buyer. In addition, an estate can be gradually reduced by consuming or making gifts of the installment payments. Where such reduction is not desired, the seller faces an aggravated reinvestment problem.

Transfers at death are least painful to the deceased. Our secret "willing" process is reasonable, but some desire exists for a public disclosure that would be binding on all parties even before the owner's death. There certainly would be management implications if it were known in advance who is to receive the property.

The absurd parts of contemporary wills relate to taxes. A one-or two-page will often is expanded to ten pages to include stereotyped marital and non-marital trusts. What could be a $25 will becomes a $150 will. This seems ludicrous to many persons and rightly so. At least 90 percent of this common language could be placed in the law and incorporated by reference in a will. With simpler wills, more would be used, which again has strong implications for management policy and choices.

The pressure of taxes sways most business decisions, and indeed the form of organization, toward vantage grounds of least impact. The slow gaited may be struck with a tax load many times that of the perceptive businessman.

Planned reductions of death taxes for an average farm estate often are equal to several hundred thousand dollars of gross income. The penalty for inaction may be an extra eight years of hard labor for someone in the family; or, conversely, it may allow retirement eight years earlier.

It is ironic that most property values have multiplied four to eight times in the past 20 years but death tax exemptions have remained static. At a time when farm firm assets are substantially increasing, the size of individual holdings is severely restricted by the impact of death taxes, and gift taxes partially absorb inter vivos transfers. It is a period in our economy when non-ownership of realty and operating assets is becoming much more attractive.

Final Comment

It may well be that a societal value judgment favoring small holdings and widespread diffusion of land ownership is superior to any possible gains in efficiency of resource use. Even after allowing for maldistribution of food resources, our nation is not suffering from an inability to feed itself. The marginal value of social gains inherent in institutional by-products may well exceed that of possible increments of food and fiber production. Our examination of instruments and institutional arrangements suggests no serious lack of means to get what we want, but rather a gross inability to agree on what is wanted, or indeed, needed.

Do Legal and Tax Rules Favor Large-Scale Agricultural Firms?*

NEIL E. HARL

THE assigned title of this paper necessarily implies an examination of the extant income tax and legal structure rather than a normative view. Accordingly, those facets of the legal and tax structure impinging upon large-scale agricultural firms uniquely and peculiarly vis-a-vis small-scale farm firms are examined herein.[1] While occasional reference is made to the legal and tax structure of the large-scale farm firm vis-a-vis comparably sized non-farm firms, that issue is not considered to be within the purview of this paper.[2]

General

Although the term "scale" has acquired general significance in economics, legal patois has never accorded the same degree of significance to scale or size per se. The relativity, dynamic character, and absence of a single descriptive dimension of size and scale have discouraged use of the terms as touchstones for legal restraints and tax policy.

Perhaps in part as proxies for size and scale, legal and tax rules have been based upon such features as form of organization, type of firm, and occupation of individuals involved. Form of organization is perhaps the most important variable in explaining differential treatment of firms legally and from an income tax standpoint. Even in instances where size or scale has been the apparent target, legislation has tended to focus on forms of organization such as the corporation. This has created anomalies in numerous instances, inasmuch as the traditional forms of organization —sole proprietorship, general and limited partnership, trust, and corporation—may be and are being used by firms throughout the size or scale range.

The title to this paper suggests, by implication, a benchmark legal and tax system against which large-scale firms should be tested in determining whether they are favored by extant legal and tax structures. Inasmuch as

the predominant organizational structure for the farm firm continues to be the sole proprietorship, the legal and tax rules relevant to "large scale agricultural firms" are tested against that standard.

Legal (non-tax) Rules Peculiarly Affecting Large Scale Agricultural Firms

State limitations

With large-scale farm firms tending toward use of the corporate form of organization,[3] interest in limiting size or scale of farm firms has occasionally been translated into restrictions limiting or denying the right of corporations to hold land or operate farm businesses [9]. Such legislation may reasonably be interpreted, at a minimum, either as not favoring large-scale agricultural firms or not favoring the corporate form of organization per se.

North Dakota law, while permitting the formation of farming cooperatives by five or more adults if 75 percent or more of the members are actual farmers residing on farms or depending principally on farming for their livelihood, has prohibited all types of farm corporations since 1932. A referendum vote in 1968 defeated an attempt to legalize closely held farm corporations.

From 1931 to 1965, corporations in Kansas could not engage in the business of "producing, planting, raising, harvesting or gathering wheat, corn, barley, oats, rye or potatoes, or the milking of cows for dairy purposes." In 1965, the Kansas law was amended to permit closely held corporations not exceeding 5,000 acres to engage in the prohibited purposes.

In Minnesota, corporations organized for and engaged in farming operations may not acquire more than 5,000 acres of land. Texas law does not permit corporations to engage in the business of raising cattle and owning land for that purpose nor the business of operating stockyards and of slaughtering, canning, curing or packing meat. West Virginia imposes a one-time special tax of 5 cents per acre on corporate land holdings over 10,000 acres. An Oklahoma constitutional provision specifying that a corporation could not "buy, acquire, trade or deal in real estate for any purposes except such as may be located in . . . cities and towns . . . and further except such as shall be necessary and proper for carrying on the business for which it was chartered or licensed," has been held not to prohibit land ownership by farm and ranch corporations. A few other states place similar broad, general limitations on corporate ownership of real estate.

---

[3] The exact number of farms operated by corporations, partnerships or trusts by size classification is not known since the Census of Agriculture has not, in the past enumerated farms by method of organization. Available data suggest that the average size of farm corporations exceeds by several times the average size of farm [12, p. 13; see also 4, 14]

Most states provide that certain property of an individual debtor is exempt from execution by creditors.[4] The exemptions are most generous in heavily agricultural states and to farmers as debtors. Property owned by a corporation is generally not similarly exempt inasmuch as exemption provisions typically apply only to "heads of families" or "married individuals."

Federal restrictions

Federal limitations applicable to large-scale agricultural firms pertain principally to eligibility for loans by federal lending agencies and rules for participation in reclamation projects. Limitations on maximum payments that may be received under price stabilization programs have been considered by the Congress from time to time but have not been enacted into law to date.

Federal lending policies.—Various types of loans from federally sponsored credit agencies are either unavailable to farm corporations or significant limitations are imposed on loans to farm corporations. Neither Farmers Home Administration real estate loans nor FHA operating loans may be made to farm corporations. Corporations engaged primarily in farming, however, are eligible for emergency loans and may participate in the emergency feed program. FHA soil and water loans may be made to corporate grazing associations.

Federal Land Bank and Production Credit Association loans may be made to a farm corporation if limitations are observed with respect to source of income, occupation of shareholders, and shareholder limited liability.

Bankruptcy and exemptions from execution.—Since the early days of federal bankruptcy law, individual farmers and partners in farm partnerships have been permitted to file a petition as voluntary bankrupts, but could not be declared a bankrupt involuntarily. A corporation engaged in farming is afforded the right to be a voluntary bankrupt but is also subject to involuntary bankruptcy if it owes at least $1,000 of debts and commits one or more of the six "acts of bankruptcy" within four months of the time the petition was filed.

Reclamation project rules.—Early federal land policies, directed toward encouragement of settlement of the west, contained acreage limitations which have been continued down to the present in various forms.

The Reclamation Act of 1902[5] limited the area for which the use of water could be sold to 160 acres. At present, water right certificates for reclamation water use on lands in private ownership are limited to 160 acres per owner unless construction charges have been paid. The sale of excess lands acquired in connection with federal irrigation projects may not exceed 160 acres per person. Under a 1953 act authorizing the exchange of tracts or additions to tracts in federal irrigation projects to create farms "sufficient in size to support a family," the maximum size of any resulting unit is 320 acres of which not more than 160 acres may be irrigable. And applicants for entry on Federal reclamation lands presently must not own more than 160 acres of land in the United States.

Differential Tax Rules for "Large-Scale Agricultural Firms"

Federal and state income tax rules have generally been developed and applied on the basis of the legal nature of the taxpayer; size or scale of the taxpayer have only rarely been deemed relevant variables in income tax imposition.

Tax rules explicitly recognizing size of firm

Expenses incurred for clearing land to make it suitable for use in farming may be deducted currently, if the taxpayer elects, rather than being added to the basis of the land. However, current deductions are limited to the lesser of $5,000 or 25 percent of taxable income from farming. This provision tends to favor land clearing by farmers with taxable incomes of $20,000 or less per year.

Other rules peculiar to farmers, including deducting expenditures for fertilizer and lime, reporting commodity credit loans, claiming deductions for soil and water conservation expenditures, and filing estimated tax returns make no distinction as to size or scale of farmer.

Depreciation and investment credit rules, except for extra first year 20 percent depreciation, contain few size or scale limits explicitly. Investment credit has been limited to the amount of tax or $25,000 plus 50 percent of the tax over $25,000. Used property eligible for the credit has been limited to $50,000 per year. During the 1966–67 suspension, the investment credit was limited to $20,000 in purchases, and a ceiling of $50,000 was placed on certain kinds of depreciable real property eligible for fast methods of depreciation. Extra first year 20 percent depreciation is limited to a maximum of $2,000 per taxpayer (including a corporate taxpayer) or $4,000 for a husband and wife filing jointly. In this instance, a farmer filing jointly with a spouse thus has an advantage over large-scale farms operated as corporations.

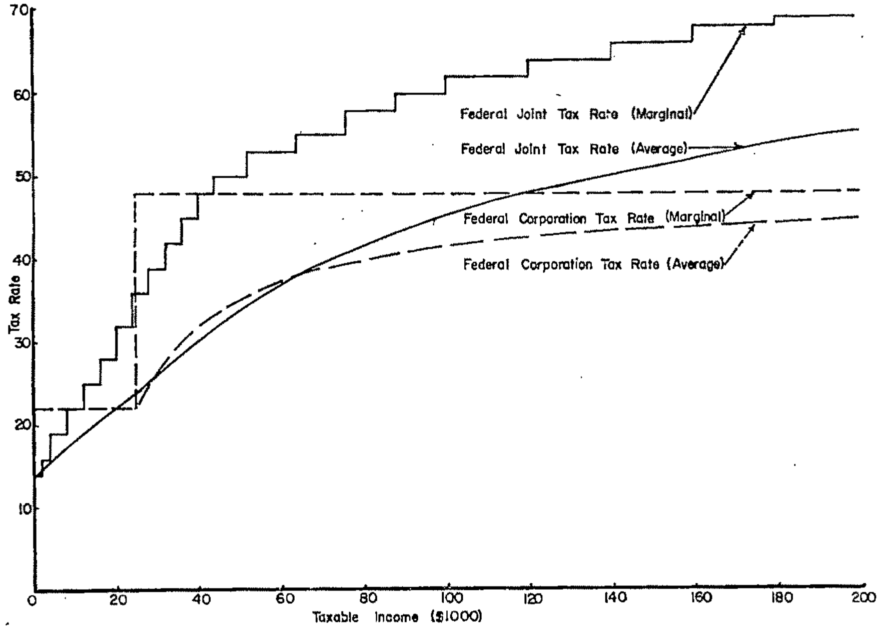

Figure 1. Individual and corporate Federal income tax rates

Differential tax rules by form of organization

Income tax differences are accorded firms operated as sole proprietorships, partnerships, trusts, and regularly-taxed or Subchapter S[6] corporations. Since sole proprietorships have traditionally not been taxed as separate entities but with the income taxed to the individual taxpayer, and since partnerships and Subchapter S corporations in effect pass income and losses to partners and shareholders, respectively, to be reported as individual taxpayers, the essential comparison is between the income tax treatment of a corporate firm and a firm operated as a non-corporate taxpayer.[7]

Comparisons between individual and corporate tax treatment are complicated by the conceptual differences between the two classes of taxpayers. Regularly taxed corporations are taxed as separate entities. Since corporations do not have ability to pay in the same sense as individuals, the corporate income tax rates do not parallel individual graduated rates [15] Currently, corporations pay tax on corporate taxable income at a rate of 22 percent on the first $25,000 and 48 percent on all taxable income over $25,000. These marginal rates compare with individual rates of 14 percent on the first $1,000 of individual taxable income up to 70 percent on taxable incomes above $200,000 for married taxpayers filing jointly. Marginal and average rates of individuals and corporations are compared in Figure 1. These rates are exclusive of the 10 percent surtax applicable for 1968–69.

---

[6] Subchapter S corporations are taxed similarly, though not identically, with partnerships. To elect Subchapter S status, a corporation may have not more than 10 shareholders who must be either individuals or estates, all shareholders must consent to the election, and not more than 20 percent of corporate gross receipts may come from rents, royalties, dividends, interest, or gains from sale of stock or other securities. In a Subchapter S corporation, ordinary income, capital gains, and operating losses are reported by the individual shareholders for income tax purposes.

[7] The tax-free exchange rules used by so-called conglomerate firms to accumulate capital through acquisitions are peculiar to the corporate form. Inasmuch as restrictive legislation is indeed likely in this area, discussion of the opportunities under current law is not included herein.

Figure 2 depicts the total income tax burden for a hypothetical firm and the individuals involved, for net incomes ranging from $10,000 to $200,000 annually, under assumptions of 50 percent (curve I (A)) and 70 percent (curve I (B)) of firm income paid out as salaries with the re-

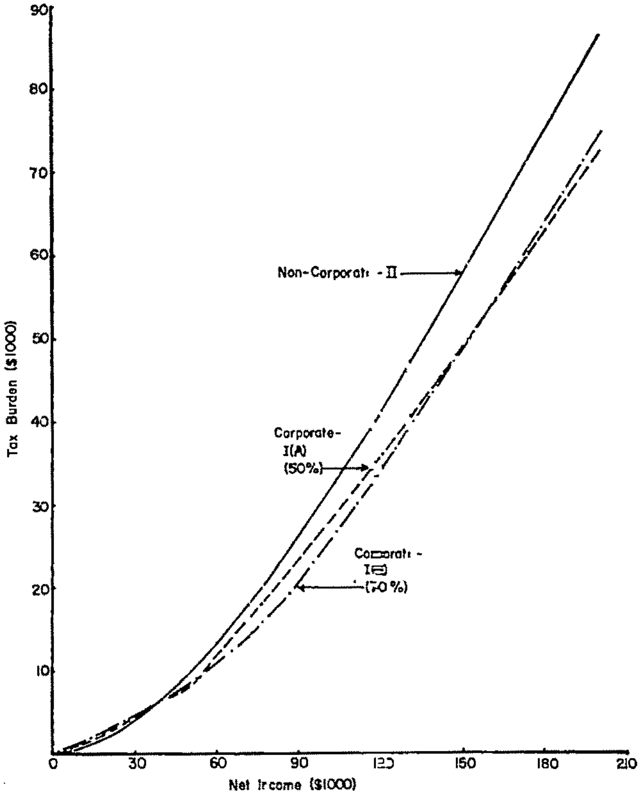

Figure 2. Total tax burden for firms ($10,000–$200,000)

mainder held for expansion under the corporate form of organization. Curve II reflects the tax burden under a non-corporate form of organization. It is assumed that each of the two individuals involved shares equally in salaries and ownership of the firm and that each claims four exemptions and the 10 percent standard deduction.

Impact of corporate income tax

Controversy has long raged over the incidence of the corporate income tax. It has been argued that the corporate income tax is in part an indirect tax insofar as it is passed on to the consumer and tends to raise the costs of goods and services and keep real wages lower than they might otherwise be [18, p. 20]. While this may be a reasonable hypothesis in imperfectly competitive industries where the corporation predominates as a form of organization, it is less persuasive in agriculture where the sole proprietorship predominates and where the impact of corporate firms on price is likely to be small. Alternatively, it has been argued that the corporate income tax is a direct tax on the shareholders and is unfair because it imposes a double tax on dividend income as compensation to equity capital before dividends are in spendable form [18, p. 20].

The relative burden of the corporate income tax varies, depending upon whether one is considering (1) saving capacity and incentives to invest, (2) systematic pressures for debt as opposed to equity financing, or (3) distortions of resource allocation over time.

Saving capacity and incentives to invest

Comparisons of corporate and individual tax rates are relevant for internal investment purposes to the extent that capital retained in the firm for expansion is subjected to differential rates of federal income tax. Quite clearly, at low income levels the individual taxpayer has the advantage; at high income levels, the corporate taxpayer is in a more favorable position as indicated in Figures 1 and 2.

In an effort to expand the benefits of the relatively favorable 22 percent rate on the first $25,000 of corporate taxable income, taxpayers have utilized multiple corporations, each complete with a separate income tax structure to place a 22 percent ceiling on taxable income. A number of provisions have been enacted to curb this practice.

After-tax capital for expansion from capital gains income, such as from the sale of breeding livestock held for 12 months or more, is substantially greater for an individual taxpayer who may deduct one-half of all long-term capital gains income. The other half is taxed as ordinary income. The maximum tax for any taxpayer on capital gains income under current law is 25 percent of the entire gain. Corporations, on the other hand, are not eligible for the 50 percent deduction and are taxed on capital gains income at 22 percent, if that is the relevant rate, or at 25 percent. The individual taxpayer, therefore, would normally not be taxed more heavily and usually would be taxed less heavily than a corporation.

Differential treatment of losses may also affect incentives to invest and expand. Individuals and corporations, under similar rules, may apply operating losses from a trade or business to income of the three prior years and may deduct from the succeeding five years' income any unabsorbed loss. A corporation may have no carryover if there has been a substantial change in the ownership of the corporation. However, where there has been no change in ownership of a corporation, past losses may be applied against income from new ventures under the same carryback and carryforward rules.

Corporations with excess capital losses may apply those losses against capital gains in the five succeeding taxable years. Individual taxpayers in contrast are allowed an unlimited carryforward period and may also offset up to $1,000 of ordinary income each year with excess capital losses. Again, the advantage rests with the individual taxpayer.

Any advantage of the corporation in terms of after-tax dollars for expansion from ordinary income must be tempered by application of the accumulated earnings tax which is peculiar to the corporation. The accumulated earnings tax is designed to prevent corporations from avoiding income tax at the shareholder level by accumulating income at the corporate level in excess of the reasonable needs of the business with ultimate distributions in liquidation at capital gains rates. A corporation accumulating more than $100,000 in earnings and profits is subject to the accumulated earnings tax (imposed at rates of 27.5 percent to 38.5 percent) unless it can be proven that the reasonable needs of the business require such accumulation and that tax avoidance at the shareholder level was not one of the reasons for accumulating earnings and profits.

Certain tax and non-tax reasons may encourage individual taxpayers to use the corporation not only to operate a business, but also to serve as the vehicle for making personal investments. One advantage of a corporate investor is that dividends received by a corporation from another domestic corporation are eligible for an 85 percent dividend received credit. At the lowest marginal rate, dividends received by corporations are taxed at a 3.3 percent rate (22 percent × 15 percent) compared to a 14 percent percent to 70 percent rate for dividends received by individuals, except for the $100 dividend exclusion. The personal holding company tax, which is designed to discourage such use of the corporation, is imposed at a 70 percent rate if 60 percent or more of "adjusted ordinary gross income" comes from passive investments and if five or fewer shareholders own more than 50 percent of the corporate stock. To the extent that the complex personal holding company rules can be avoided, a distinct capital accumulation advantage exists for the corporation.

For capital accumulation at the level of the individual, use of the corporation creates a double tax burden as dividends are paid out of after-tax dollars at the corporate level and are taxed to the shareholders as ordinary income upon receipt except for the $100 dividend exclusion. The double taxation aspect tends to encourage the expansion of existing successful corporations and intensifies their search for profitable investment opportunities as funds are retained at the corporate level.

Debt vs. equity financing

The income tax treatment of corporate inputs typically creates both internal and external manifestations with respect to the firm. Interest as compensation for debt capital, salaries and bonuses as compensation for labor and management, and rent as compensation for leased inputs are all tax deductible at the corporate level and taxable to the recipient as ordinary income. Dividends, however, as one means of compensation for equity capital, are not tax deductible at the corporate level and, as noted above, are taxable to the recipients except for the $100 dividend exclusion under federal income tax law. Therefore, an incentive exists for corporations to pay out earnings in tax deductible form, thus encouraging a skewing of the income distribution schedule in favor of higher levels of tax deductible payments where some measure of identity exists among the shareholder-creditor-employee groups. Only in Subchapter S corporations are dividends, interests, salaries, and rent treated substantially alike for tax purposes.

The tax advantages of interest payments compared with dividend declarations encourage the use of bonds, debentures, and notes in a corporate financial structure. Heavy use of debt financing may result in a "thin" corporation with a weakened balance sheet, high fixed rate interest payments that do not fluctuate with the earning power of the corporation, and Internal Revenue Service challenges to the debt securities as essentially additional classes of equity securities with disallowance of interest deductions.

Decision making subsequent to death of equity capital contributor

Under current law, death of a property owner produces a new income tax basis for most property. The basis becomes equal to fair market value as of the date of death (or as of the ultimate valuation date up to one year after death) with the potential gain in the property eliminated. This provision of the tax law has been criticized as an inequitable loophole favoring principally landowners and shareholders, and repeal has been suggested in recent years.

For a farm operated as a sole proprietorship, with the farmer owning the property personally, the rule has several effects on decision making. The new basis at death enables the successors to set up a new depreciation schedule after death even though the property had previously been fully depreciated. Upon sale of the property subsequent to death, the amount received would not be taxable up to the date-of-death value. The tax-saving incentive may be so great as to (1) discourage lifetime gifts of heavily appreciated property[8] and (2) encourage the placing of high values on property at death (with due consideration of marginal income tax rates and marginal death tax rates).

For farmers operating in corporate form, the effect of death of the equity capital contributor is substantially different. Upon death of a shareholder, the income tax basis of the stock becomes equal to fair market value with the potential gain in the stock eliminated. However, a shareholder death has no effect on the income tax basis of corporate property. Therefore, once corporate property is fully depreciated, no additional depreciation is claimable by virtue of death of a shareholder, even a shareholder owning all of the corporate stock. Similarly, all of the gain on corporate property is fully taxable upon sale of the corporation.

This differential effect by form of organization may be substantial in farm businesses where a farmer as a decedent typically owns heavily appreciated property. Tax reform proposals under consideration in the Congress in recent months would reduce the magnitude of this differential effect significantly.

Employee or self-employed status

The employee status accompanying corporate organization of large-scale farm firms typically poses both advantages and disadvantages compared with the self-employed status of sole proprietors. In most instances relatively more social security tax is paid, inasmuch as self-employed farmers pay tax (which is not income tax deductible) at a rate of 6.9 percent (for 1960–70) on the first $7,800 of earnings from self-employment. For a corporate employee, the tax is levied at a rate of 4.8 percent, with a like amount imposed on the corporation for a total of 9.6 percent. The difference, at the maximum income level, would be $210.60 per employee per year.[9] Moreover, while wages earned by a minor are not subject to social security tax if he works for his parent, his wages are subject to the tax if paid by a corporation.

Participation in various employee benefits is available only to employees and not to a sole proprietor or partner in a partnership. Group term life insurance, health and accident insurance, stock option, and deferred compensation benefits are available to eligible employees [11]. Of these benefits, only deferred compensation plans are available to the self-employed farmer and then on less advantageous terms.[10]

---

[8] For property given away during life, the income tax basis for the gift property normally carries over, with the potential gain intact, to the recipient.

[9] The employer's share is income tax deductible, however.

One income tax advantage accompanying employee status relates to treatment of personal living expenses. Lodging and food costs, as personal expenses, are not deductible by a sole proprietor. However, meals and lodging furnished to an employee for the convenience of the employer are deductible by the employer and do not constitute taxable income to the employee. It has been argued, sometimes successfully, that farm employees may reasonably be required to accept lodging on the premises for the convenience of the employer and as a condition of employment, with the result that meals and lodging are provided tax-free.

Conclusions

Generalizations as to the differential effects of the legal and tax structure by size of farm firm are suspect; the variables are many, and the facts of each situation are unique and determinative. However, it appears on balance that the legal and tax structure does not discriminate systematically against small-scale farmers and for large-scale firms. Rather, numerous instances have been cited where the smaller-scale farmer qualifies for special treatment and escapes limitations imposed directly or indirectly upon large-scale firms. The major advantage of the large scale corporate firm in reporting taxable income at a maximum of 48 percent could scarcely be considered an advantage when compared with the lesser rate for many individual farmers. However, the corporate tax structure does provide strong encouragement for corporate operation by high-tax-bracket individuals. The tax advantages of employee status are available to employees of sole proprietors and partnerships but not to sole proprietors themselves and generally not to partners.

While it is not surprising that state and federal laws do not discriminate in favor of large-scale farm firms, a relevant policy question is whether state and federal laws should discriminate to a greater extent in favor of small-scale farm firms or whether a position approaching neutrality should be sought.

Whether large-scale firms engaged in farming have advantages not available to large-scale firms in other sectors was not fully examined in this paper. If in fact such advantages exist, and there is some evidence of such advantages,[11] large-scale firms may be encouraged to enter farming even though operating under a somewhat less advantageous structure than small-scale farm firms. Economies or diseconomies of size may be important, however, and may dwarf differential legal and tax effects.

---

[10] For example, up to 15 percent of employees' compensation may be set aside in a qualified profit-sharing trust, whereas only 10 percent of earned income (maximum of $2500) may be set aside under the Self-Employed Individuals Tax Retirement Act.

Legal-Economic Models as a Tool for Optimizing Intergeneration Property Transfers*

DONALD R. LEVI AND JAMES K. ALLWOOD

THE trend to larger agricultural production units, together with inflation, has increased both the net value of the typical farm family estate and the resulting death tax liability.[1] Since the minimum estate size to which federal estate taxes apply[2] has not changed over time, more farm estates are now subject to this tax. But many farmers are unaware of the law or the extent of capital erosion accompanying intergeneration property transfers. This erosion often can be significantly reduced without sacrificing current consumption. Thus the rational manager can no longer afford to ignore legal rules affecting intergeneration transfer costs.

The magnitude of capital erosion through federal gift and estate taxes was illustrated by Allwood [1, p. 85] for five estates ranging in value from approximately $225,000 to $1,800,000. Assuming a family of five in which the 58-year-old husband and 56-year-old wife lived normal life expectancies, he found differences in transfer costs between optimal planning and no planning ranging from approximately $36,000 to nearly $456,000.

However, benefits from estate planning include factors other than intergeneration transfer cost minimization. Some insight to these is revealed when one considers the basic objectives of estate planning, as follows:

1. To provide adequate security for retirement.
2. To assure each asset is transferred to those of the owner's choice.
3. To minimize intergeneration transfer costs, consistent with achieving the above objectives.

The relative importance of these objectives may vary among estate owners, depending on the nature, extent, and value of assets, the availability of other funds for retirement, the vocational preferences and equitable treatment of heirs, consumption patterns and needs, personal preferences and other factors. Since different individuals attach differing

weights to these items, it becomes apparent that personal satisfaction, a factor not readily susceptible to quantification, is the criterion estate planners implicitly seek to maximize.

Previous Work

Conceptualization

While Schulz [9] suggested roles for economists in estate planning, the conceptualization of using legal-economic models to optimize intergeneration farm property transfers appears to have been an outgrowth of Harl's dissertation [3]. His envisioned use of the model developed therein was as follows:

> At a less theoretical level, some sections of the model may, with suitable modification, be utilized in professional disciplinary practice. Thus, the portion of the simulation model representing the personal estates of owners of the firm may be adaptable for use in estate planning. At relatively low cost and extreme rapidity, a vast amount of data could be generated for professional evaluation based upon the application of alternative estate plans to a particular set of estate planning data provided by a client. Similarly, the decision-making precision as to choice of form of business organization for a client could be improved by applying, statically or dynamically, the various formulations of the models to a client's factual situation [4, p. 100].

To summarize, the purpose of such a model, whether deterministic or nondeterministic, would be to provide the client with more and better information upon which to base decisions. It should not be expected to yield a plan to be blindly followed.

Multi-period linear programming model

Harrison [5, 6] appears to be the first in the profession to develop a model specifically designed for use in estate planning. He used a multiperiod linear programming model maximizing the undiscounted value of property transferred equally to four heirs by a widow with a five-year planning horizon. The model considered inflation, earning capacity of assets, the widow's consumption requirements, and benefits from social security, medicare, and a medical insurance program.

Since gifts made within three years of death may be subject to federal estate tax on the theory they were made in "contemplation of death,"[3] Harrison actually used a two-year effective planning horizon. While it can be argued that manual calculations of gift tax exemptions and exclusions is more efficient than using the computer for this length of planning horizon, it should be noted that his model can readily be expanded to longer planning periods. Harrison's model also envisions planning to be initiated after one of the spouses has passed away. While unfortunately this often is the sequence of events in reality, it would not necessarily maximize property transferred to the succeeding generation.

---

[3] Under section 2035 of the Internal Revenue Code, any such gift is presumed to have been made in contemplation of death and will be subject to federal estate taxes unless this presumption is rebutted.

A static linear programming model

Allwood [1] developed a static linear programming model with the objective function of minimizing the summation of federal gift and federal estate taxes[4] associated with the intergeneration transfer of assets from both spouses. He assumed an equal division among three children whose parents had, respectively, 17- and 22-year planning horizons. The model was designed to select the optimal transfer activities from among seven alternatives (see Figure 1). Allwood assumed that consumption would not exceed asset earning capacity plus social security benefits and that assets would not change in value over the planning period.[5] Thus, neither his model nor that of Harrison included all relevant estate management factors for the typical farm family.

The potential use of deterministic estate planning models

Deterministic estate planning models can be criticized as assuming certainty not existing in the "real world." However, estate planners implicitly use a deterministic "model" when developing an estate plan, with the form of such plan reflecting the assumptions regarding the client's personal circumstances. A formal model merely makes these assumptions explicit. Thus, the validity of the aforenoted criticism is dependent on the expected contribution of the particular legal-economic model. The criticism may well be valid if one expects the model to outline a plan that yields optimal results in all cases.

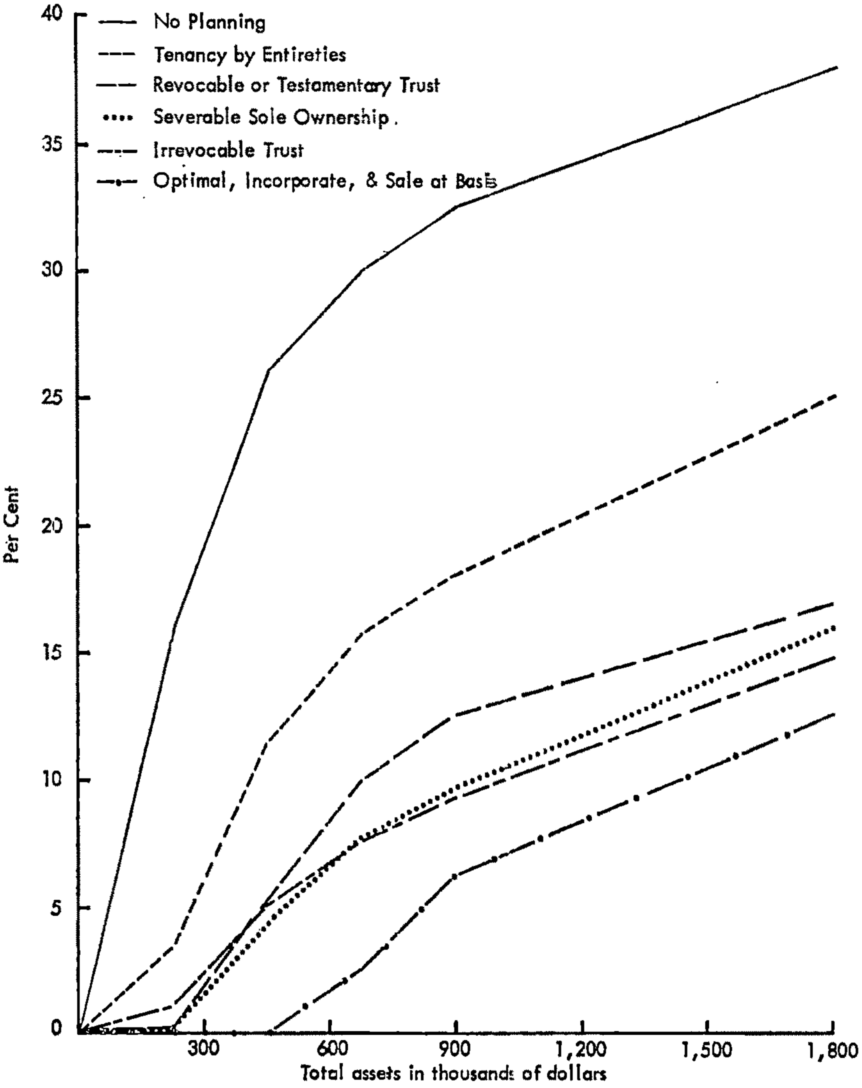
To avert some of the problems of risk and uncertainty, such factors as a probability density function for life expectancies could be utilized in the models, although knowledge of a given client's health might be of greater benefit to estate planners in many cases. Potential but unpredictable (or at least unpredicted) changes in external factors, such as the general price level, may mean that the model would yield varying cost minimization strategies if computed at different points in time. Thus, the irreversibility of certain strategies (e.g., sale) should be recognized, and alternative courses of action and their associated costs carefully investigated.

---

[4] Depending on estate size, I.R.C. 2011 permits varying amounts of state death taxes paid to be subtracted as a credit from the federal estate tax due. When such state death taxes are less than the allowable credit, many states assess an additional tax in the amount of the difference (e.g., see R.S.Mo. Ch. 145.070 (1959)). Under this situation, the magnitude of state death taxes will not affect intergeneration transfer costs, permitting them to be excluded from the objective function.

[5] The former may have been justified, given the estates examined. The latter is somewhat unrealistic, although often used in practice by estate planners.

Figure 1. Total tax as percent of total assets of husband and wife, optimal and forced solutions



Allwood's work indicates that a deterministic model can provide information not generally known to estate planners. While his model selected sale of the family farm at market value (to a son interested in farming) as the optimal strategy [1, p 82], cost data were obtained for comparative purposes by successively forcing the other six activities into the solution. Figure 1 shows these activities and the cost associated with each as an estate increased in value from approximately $225,000 to slightly more than $1,300,000. In addition to illustrating the significant savings that can be achieved by proper planning, Figure 1 also shows how the relative costs of various transfer activities change as the estate increases in value.[6] Many estate planners may be unaware of these changes, and few would be likely to know the exact level at which they occur. Thus, such a model could provide helpful information in this regard.

Potential Models and Extension

The effectiveness of any legal-economic estate planning model can be evaluated only after specifying both the purpose for which it is to be used and the estate owner's personal planning objectives. The authors tend to believe models providing estate planners with more and better information are likely to be adapted in practice, as implicitly suggested by Harl. For some, a relatively simple model may suffice.

Marginal analysis-opportunity cost models

For those whose estates are not large enough to be subject to federal estate taxes, retirement security may often be the major estate planning objective.[7] To this end, depending on the length of the planning horizon, a simple opportunity cost model involving alternative investment opportunities, income flows, anticipated social security and medicare benefits, and other factors may meet the need for assistance. However, a more sophisticated approach may be required if the estate is large or if the planning horizon encompasses more than one intergeneration transfer.

Linear programming

Either Allwood's static or Harrison's multi-period linear programming model could, with appropriate modification, be adapted for practical usage. Such a model might include specific allowances for inflation, asset earning capacity, consumption requirements, social security, medicare, and medical insurance benefits, and could permit election of optimal transfer activities in light of the circumstances of both spouses among various alternatives. Other factors, such as a Keogh retirement plan and credit needed for growth might also be included. Such models might be either deterministic or probabilistic if probability distributions are incorporated for such factors as life expectancy, income flows, etc., in the manner of Johnson et al.[7].

Simulation

The potential use of simulation to link theoretical models with reality is well known. It might have two distinct uses with regard to estate planning. First, several computer runs could be made to provide intergeneration transfer cost information for alternative strategies or for such factors as the order of death within the family, while making deterministic assumptions with respect to such conditions as the length of the planning horizon. Estate owners could then evaluate this information in light of family circumstances and objectives and select the transfer activities that maximize personal satisfaction.

---

[6] For an explanation of why such changes occurred, see [8, p. 279].

[7] For a discussion and examination of achieving such security by participating in Keogh retirement plans for self-employed persons, see [10].

Second, the technique could be used in conjunction with a probability density function for life expectancies to generate the probability distribution of costs associated with a given policy. This, together with the cost information generated and knowledge of the health conditions of the various parties, could greatly aid in the selection of the appropriate transfer activities.

The fact that such models are quite complex would of course be considered a disadvantage if a unique model had to be developed for each estate owner. However, once a simulation model capable of general usage is developed, complexity would be important only to the extent that it increased the cost of generating the desired information.

Concluding Comment

This paper has merely scratched the surface in discussing the potential use of legal-economic models as a tool in estate planning. The field is wide open, limited only by the ingenuity of the researcher.

Discussion: Agriculture and the Law

THOMAS F. HADY

Heaven, for a discussant, might be defined as a group of papers in which there are errors of fact and logic with which he can loudly disagree. In these papers, however, I have not found this kind of heaven; I find nothing of consequence to correct. All of the authors have done a thoroughly professional job on their papers.

Since I see little to quarrel with, perhaps the most useful thing I can do is to look at the same subject matter from the standpoint of a set of interests slightly different from those of the authors and try to discuss further some of the same points that seem to me particularly important.

A recurring point in the Krausz and Reiss paper is the problem of finding an equitable distribution of costs and revenues. Two related topics are involved here: equity, or some sense of what people in general think is fair; and efficiency, as economists define it. Our society as a whole appears to consider it equitable that people be compensated in proportion to the value in production of the resources they own (with strong reservations, however, in the case of the poor). When the same individual owns all the resources used on the farm, errors in the compensation of each factor cancel out and do not affect equity. This is not true, however, when someone else owns some of the resources. It seems to me that the point Krausz and Reiss are making is that the growing number of instances in which the bundle of resources used in farming are owned by different people has made it much more important that these people know the "value"—the marginal productivity—of their inputs. It provides a further incentive, if we ever needed one, to help farmers and other resource owners to obtain better management data and to make better decisions.

The economic efficiency problem seems to me more difficult. At least since Adam Smith and his "invisible hand," economists have relied on the market to provide an optimal distribution of resources in production. We know more about the conditions under which this optimum will be produced than Adam Smith did, but we have not, by and large, deviated from the principle. The availability of institutions to combine inputs owned by different individuals may remove some institutional barriers which otherwise would have prevented an optimal combination of factors of production in farming. The fact, however, that these inputs are owned by different people should not, in itself, affect efficiency. A farm with given quantities of land, labor, capital, and entrepreneurship is the same

---

THOMAS F. HADY *is with the Economic Development Division, Economic Research Service, USDA.*

productive unit whether those inputs are owned by one person or by several. Further, imperfect information about marginal-value-products seems no more likely to produce misallocations of resources whether the resources are owned by one person or several. Market imperfection in the form of elements of monopoly or monopsony in the factor markets are another story. We may need to take a closer look at the effects on economic efficiency of the new structure of factor markets in agriculture.

Krausz and Reiss also raise the question of the exemptions from the death tax and appear to suggest, as others have suggested, that these exemptions are too low; death taxes may be interfering with intergenerational transfers of farms. Unquestionably, there are operating units for which this is true. (One of the reasons for which death taxes have been advocated is to prevent large accumulations of individual wealth.) Based on some preliminary spadework a few years ago [1], I remain skeptical that this is a serious problem for the typical farmer. The important point, however, is that this is a question on which researchers could provide much more information than they have provided. For farms of various types, sizes, and ownership patterns, what would the death taxes be under careful estate management? Would borrowing that amount impose particular hardships on the heirs? Would the fact that they were forced to borrow affect the long-run growth of the farm firm in any foreseeable ways, and, if so, how? What effects will death taxes on farms have on the economy as a whole, and do those who inherit farms experience problems that other heirs do not? Researchers trained in agricultural economics and in law have provided a real service in producing bulletins to help farmers with estate planning (and Krausz is a coauthor of one of the best of those bulletins). Now we should go the next step and make an effort to find out what the effects of these laws really are.

Levi and Allwood have provided a start in that direction, with their discussion of legal-economic models. Their discussion seems to be directed primarily, however, at the legal-economic model as a tool for estate planners. I would suggest that these models are likely to be of much more immediate use to those who are interested in the effects of various changes in public policies and laws—the sort of changes Krausz and Reiss discuss. I would suggest that designers of these types of models consider this use specifically and design the models so that tax rates, exemptions, and other legal provisions can be varied. Then we shall need to work out means of better evaluating the effects on the economy of the conclusions we draw from those legal-economic models. Perhaps we are working toward the day when we can weld these models together with models of agricultural production, such as those being developed in ERS, and models of the overall economy and simulate the answers to questions such as the economic effects of changing the exemptions on the death tax. I hasten to add, however, that we will not then have designed a computer system for writing our laws. We still do not know how to define, let alone build models of such concepts as equity. I must also confess to some lingering doubts as to whether this type of "building models" is the best way to attack these research problems.

Harl's paper gives us a good discussion of the legal advantages and disadvantages of large-scale farming. The shortage of economic analysis of the effects of these laws is not Harl's fault; the research has not been done. Further, I have become increasingly convinced that if we are to understand the impact of tax provisions and similar laws on the structure of American agriculture, we are going to have to change some of our fundamental habits in agricultural economics research.

Traditionally, we have devoted most of our efforts to studying the "typical" family farm. This farm does not seem to be the place to study impacts of tax laws on the structure of agriculture. These effects seem to show up in the "atypical" farms—the very large farms and those that are integrated in some fashion with other, nonfarm businesses. We appear to know very little about these farms. We hear that a corporation in some unrelated industry like trucking has bought a large farm, but we have no notion of what made the farm attractive to it. Perhaps we need, for a start, some case studies of situations of this type, designed to give us a better understanding of the ways in which farms fit into a conglomerate business structure.

These studies will require a new set of skills. It seems doubtful that many of the firms will give us access to their records, in the same way that the typical farmer does when he answers a questionnaire. Perhaps we can borrow some tools from economists who have specialized in problems of business structure and monopoly. We shall also have to forge some new tools of our own. However we do the job, it remains a job that needs to be done.

I think we can agree that these papers have made important contributions to a subject that has been neglected for too long. Let us hope that this neglect will not continue.

INDUCING ECONOMIC DEVELOPMENT IN LESS DEVELOPED COUNTRIES

CHAIRMAN: CLIFTON R. WHARTON, JR., MICHIGAN STATE UNIVERSITY

Foreign Aid for Agricultural Development: Philosophy and Implementation

JAMES GILBERT EVANS, SR.

ACCORDING to a definition carefully selected from a Webster dictionary, "Philosophy investigates the most general facts and principles of reality and of human nature and conduct . . . it is concerned with evaluation."

The Human Condition—Present and Prospective

A philosopher once wrote that "men build their cultures by huddling together, nervously loquacious, at the edge of an abyss." The current abyss is the threatened depth of chaos into which mankind may fall unless people are enabled to share more fully and equitably in the benefits flowing from the application of science and the use of inanimate energy. Presently, of a world population of nearly 3.5 billion, about 2.5 billion live close to the level of subsistence; only a billion live above this level; a few, far above it.

We become even more nervous and more loquacious when we contemplate that an additional 3 billion inhabitants will be on the scene within four decades. After several million years, a billion human beings inhabited this earth by 1810, two billion by 1925, and three billion by 1960. Apparently there will be four billion by 1980, five by 1993, and six shortly after 2000, if not before. A median estimate for the year 2000 places the death rate in the world at 9 per thousand and the birth rate at 25, leaving a natural increase of 16. At present, the natural increase is approximately 18 per thousand [20]. A reasonably stable world population cannot, therefore, be achieved for at least another half century, even assuming tremendous and successful efforts to reduce the birth rate. By that time, the human inhabitants of spaceship earth may easily number 8 billion.

Out of a probable world population of 6.2 billion in the year 2000, Asia will have 3.5 billion, more than half the total and almost double its present number; Latin America, 640 million; and Africa, 770 million—each

---

JAMES GILBERT EVANS, SR. *is visiting professor of agricultural economics at the University of Maryland.*

more than double its present number. Combined, these continents will have nearly 5 billion of the world's 6.2 billion. Europe, Northern America, and Oceania, with but 1.2 billion, will become a relatively small pebble on the world population beach [13].

Per capita income in mid-1968 in Asia was estimated to be approximately the equivalent of $128; in Africa, $123; and in Latin America, $344. The per capita income in agriculture on all three continents is well below the average. The more populous Asian and African countries have per capita incomes under $100. Per capita income in Northern and Western Europe is above $1,500, while in Northern America it is above $2,700 [13].

Gaps in the human condition are also extreme within national societies. In India, for example, the richest fifth of the population receives at least one-half of the total national income, while the poorest 20 percent gets about 5 percent. The richest two-fifths receives 70 percent and the poorest three-fifths only 30 percent [10, App. 14]. Some of the high per capita income countries do only slightly better. In the United States the richest fifth of the families have about 44 percent of the national income while the poorest fifth get less than 5 percent. The richest two-fifths get 68 percent and the poorest three-fifths get 32 percent of the national income [22].

Although per capita income is only a rough approximation of living levels, there is no doubt that social conditions in the low income countries are more deficient than in higher income countries. Life expectancy is lower; infant mortality is higher; illiteracy is greater; a lower percentage of school age children is in school; nutritional deficiency is more severe; and housing, clothing, and recreation more inadequate. To this huddle of agriculturists, the abyss must seem especially wide and deep because families working in agriculture around the world probably comprise at least two-thirds of those living close to subsistence.

Empathy for our fellowmen and awareness of the potential of available scientific knowledge have led to the belief, rather widely held in the high income countries, that these "extremes of poverty which shorten, cripple, and undermine the values of human life" can be removed. Those living close to subsistence are also aware of the possible benefits from advances in technology and have come to expect a better life for themselves and certainly for their children. Over the years, these expectations will surely rise higher and higher.

Development Goals and Strategy

Increases in per capita income, total output of goods and services, gross national product, or the rate of economic growth are customarily regarded as evidence of development. It is one of the great ironies of our time that these "economic indicators have become so much a part of our thinking that we have tended to equate a rising national income with national well-being" [22]. They are neither acceptable measures nor the Holy Grail of development. Talk of closing the per capita income gap between affluent and poor countries is both naive and unfortunate. It is naive because this gap will surely widen in the decades ahead, considering relative population growth and relative capacity for advance in technology. It is unfortunate because whether the gap widens or narrows is no concern of the poor countries, and it diverts attention and resources from the highest priority goals. What is important and what can be achieved is provision for adequate nutrition, medical services, education, employment, and recreational opportunity.

Chief S. O. Adebo of Nigeria appraises the situation with realism: "Most people speak of bridging the gap between the poor and affluent countries. I prefer myself to put it differently. I see the problem as one of securing a decent standard of life to the millions of people condemned to live below the subsistence level and the millions who do only slightly better. For these people the question is not one of affluence, it is one of survival" [1].

Latin American countries participating in the Alliance for Progress have agreed to work toward the achievement of maximum well-being "with equal opportunity for all" and to make "the benefits of economic progress available to all citizens of all economic and social groups, through a more equitable distribution of national income, raising more rapidly the income and standard of living of the needier sectors of the population."

The late T. J. Mboya, in presenting the development plan for the years 1966-70 to the people of Kenya, stated that "the aims of the government are clear, to achieve high and growing per capita incomes, equitably distributed, so that all are free from want, disease and exploitation, while at the same time ensuring and guaranteeing political equality . . . social justice, human dignity . . . and equal opportunities . . ." [7]. Unfortunately, higher per capita incomes are not automatically distributed equitably and do not necessarily free those at the bottom of the human heap from want, disease, and exploitation. Belatedly, the Pakistan Government Planning Commission discovered that "growth is not an end in itself, it must be accompanied by social justice" [4].

No nation can point with pride to an increase in per capita income unless such an increase is reflected in the level of living of the poorest half or two-thirds of its citizens. *Development occurs when resources are allocated to produce the goods and services essential to human well-being in increasing quantities and when the people in greatest need are able to obtain and consume them. Agricultural development occurs when the quantity and quality of resources are being improved and combined effectively* *to maximize output and when the institutional environment is being modified to insure that the output is used directly and indirectly for the well-being of cultivator families.*

A United Nations report on transformation of the agrarian structure concludes "that far greater effort should be devoted than has been applied so far to economic and social development in the neglected rural areas where most of the population lives and will continue to live for decades to come" [19]. Transformation of the agrarian structure has so far been slight indeed. André Postel-Vinay of France considers the major error in the thinking and direction of development efforts to have been their "inadequacy in improving the standard of living of the rural population" [18]. This error has resulted from a failure to recognize that *dealing directly with poverty, malnutrition, exodus to cities, growth of slums, and unemployment has the highest priority in development policies and programs.*

How the Level of Living of Cultivator Families can be Improved

One of the most powerful institutions accounting for inequity in the distribution of well-being in agriculture is the land tenure system, "which defines social class relations more than does any other institution in most of the world's agrarian countries, controlling or at least limiting the power of choice and action of individuals and families, rationing economic opportunity and determining the inter-personal distribution of production and income and the extent to which economic incentives become meaningful to farm people" [21]. There is wide variation in land tenure systems ranging from plantations and large farms with hired labor, through sharecropping and other forms of tenancy, to cultivator ownership. A tenancy system prevails in most of the low income countries. Landless laborers are numerous and generally receive no more than a subsistence wage [15]. Until these conditions are changed, cultivator families will continue to live close to the subsistence level. Furthermore, agriculture cannot absorb the prospective increase in the rural labor force without worsening the well-being of farm people. Some additional land can be brought under cultivation in Africa and Latin America, but such expansion would not take care of the major portion of those needing employment.

Two lines of action are required to raise the level of living of cultivator families above subsistence: First, they must share in farm land and capital income, because a rapidly expanding labor force seeking employment will keep labor income from rising significantly; and second, non-farm employment opportunities must be created that are at least commensurate with population growth.

The need for land income to supplement labor income and provide other benefits to cultivators can be met only under appropriate land tenure and tax policies. Cultivator ownership of land or cultivator sharing of land income under cooperative or other institutional arrangements is therefore imperative, together with provision for taxation to support adequate educational health, and other services. There are, of course, no model land tenure or tax systems for universal adoption.

Already it is obvious that the towns and cities in the poor countries are not providing employment opportunities to those who come from the farms and rural areas in increasing numbers and there is no prospect that they will do so in the future. Even now cities in Latin America, Asia, and Africa have become "cancerous growths," in spite of their modern appearance.

We have become loquacious about the urgency of growing more food and the imminence of famine in view of the population explosion, and properly so. Yet, considering the breakthroughs in food production, nutrition requirements can probably be met even for 8 billion people. If famine occurs, it will be either because resources are not being allocated for the production of enough food or because those who are starving cannot get it, although a supply may be close at hand. Today there is hunger and malnutrition in areas where food is abundant, but employment and purchasing power are absent.

A most general basic fact of reality is that for the next half century *the greatest challenge facing the technologically less-developed countries will be the creation of employment opportunities, largely in rural areas, through establishing relatively small-scale labor-intensive industries for processing agricultural products and inputs and for manufacturing consumer goods for rural people.*

According to McRobie, ". . . it is in the rural areas and small towns of developing countries that an appropriate technological base must be built up. . . The essence of the task is to provide the rural areas with technologies which are more productive, more useful for controlling the environment without making them too expensive and sophisticated to be out of reach of the great majority of the population. One of the essential characteristics of such technologies would be that they are widely reproducible from indigenous resources. . ." [8].

Dependence on spontaneous individual action to create employment opportunities on the vast scale required is not feasible; national governments necessarily have this responsibility, possibly using some type of development corporation that would promote the spread of electric power to villages and the formation of small-scale labor-intensive processing and manufacturing plants. Although the production units will vary in scale, they will generally be small, but the organization for establishing them and providing for their overall management and coordination must be large scale. Development is a deliberately directed process, managed by a government with broad functions and responsibilities and powerful enough to plan and execute its policies and programs. There is no formula or standard pattern for development that fits all societies; each society must invent new political and economic structures and management techniques to meet its special needs.

Technological underdevelopment in agriculture means that the labor force is poorly educated, largely unskilled, badly housed, and has a high incidence of disease and malnutrition; furthermore, little inanimate power is used, which limits tools and machines to those requring only animal and human muscle for their operation.

There are thus two inseparable aspects of technology—two sides of a coin: One consists of educated and skilled people; the other, the tools, machines, and inanimate power, transportation, and other facilities that people design, operate, and use. Therefore, basic to technological improvement in rural areas is elementary education. As Peaslee has pointed out, ". . . in the last hundred years significant economic growth has been achieved only in those countries in which a high proportion of the total population is found in primary schools. . . . After primary enrollments have become high in the more economically successful countries, the emphasis on education has been shifted onward to the secondary and higher education levels" [11]. Universal compulsory elementary education is especially important in the less-developed countries because it makes possible a fuller utilization of human resources. Preparing children for nonfarm employment has high priority, even though more than 15 percent of the total population would be in elementary schools.

That "the technological revolution spreads in inverse proportion to institutional resistance" is a most general principle of reality [2]. Presumably, the higher the education level in a society, the greater the prospect that the "crust of custom" can be broken and institutions modified. An educated people will surely be more responsive to the need for smaller families. People must change before institutions and customs can be changed.

Small farms, which predominate in the low income countries, reflect a combination of land, labor, and capital resources dictated by the technology and institutions inherited from past centuries. With the quality and capacity of human resources being raised through various types of education, a different combination is possible even though the amount of land in each farm cannot be increased. The only feasible way to increase the productivity of cultivators is to adapt improved practices, techniques, and institutional structures to small farms. This appears to have been rather successfully accomplished in Japan. Cultivators own their farms; are primary school graduates; have been able to make use of modern science and inanimate energy; and have the benefit of an institutional structure, largely cooperative, which enhances and protects their economic position. Japan has also succeeded in providing off-farm employment opportunities to cultivator families, which is a source of more than one-third of their average income [5, 23]. While Japanese experience and institutional structure cannot be exactly duplicated in any of the developing countries, they indicate that cultivators can be served and protected in obtaining inputs and credit and in marketing crops and that small farms are not necessarily a roadblock to a better life for cultivator families.

Foreign Aid, National Interests, and Agricultural Development

That words are used to mislead and cover up is a most general fact of reality. It is reported that the most difficult problem of the Pearson Commission on International Development is in reaching agreement on the "objectives of aid policies of the donor countries," which includes "the very difficult problem of defining aid," and the examination of the assertion that "aid has been largely irrelevant to growth" [16].

So-called "aid" for development is provided by so-called "donors" to so-called "recipients." Neither aid nor donor nor recipient properly describes what is going on. Perhaps it would be appropriate to refer to aid as involvement of the more developed countries in the economic, political, military, and social sectors of less-developed countries, either directly or through international agencies.

Donors may be foreign governments, corporations, individuals, international organizations or private foundations. Aid may be people serving as actual workers or as advisors endeavoring to transplant knowledge, techniques, and institutions, or it may take the form of commodities, tools, and machines. These items may be provided as gifts, loans, or investments. Loans and investments comprise the great bulk of aid.

What are the objectives of the "aid policies of the donors?" They are a mixed bag, mainly economic and political with a dash of the humanitarian. One of the most general facts of human nature and conduct is a "tendency to assume that things which are associated in the society we know must necessarily be associated in all other societies" [6]. Perhaps it is perceptive to observe that our aid is "rooted in a concern for foreign societies *not as they are but as they might be reformed and reconstructed according to our own values and experience*" [12].

Noting that what we call private enterprise has been associated with our phenomenal technological advance and economic growth, we conclude that all other societies should have it, consequently restricting to the minimum the functions and responsibilities of their governments. Noting further that these low income countries do not have comparable quantities of inanimate energy, machines, factories, transportation, and other facilities found in the technologically advanced countries, we conclude that what they need are large injections of capital obtained through foreign loans and investments. A United Nations Panel on Foreign Investments in Developing Countries, meeting in Amsterdam in February 1969, called for a massive increase in the flow of foreign capital to developing countries in order to provide a reasonable rate of per capita growth [17]. These conclusions, though they may be false, have been accepted more or less voluntarily by many of the developing countries, resulting in heavy obligations not only to foreign governments and international lending agencies, but also to private investors who have acquired the privilege of exploiting mineral, forest and land resources to produce commodities for export and the privilege of building electric power, communication and transportation facilities, and industrial plants. In this way the donors promote their own exports, obtain raw materials and make very substantial profits. These operations are assumed to be in the national interest both of the donors and the recipients. What is good for the donors must be good for the recipients! This concept of the national interest rests on the further assumption that "the way to a better living for the people of all nations is in the direction of integrating their economies with those of other countries so that they can maximize their access to the markets and resources of the world" [3].

These assumptions may also be false, depending on the connotation of national interest. Is the greater national interest of the American people best served by lending and investing abroad or by using the resources involved to rebuild their cities? Is the greater national interest of the people of a less-developed country served by having foreign investors exploit their natural resources and build their industries before they have the capacity to do this by themselves? Will the poor economies be able to protect their interests when they are integrated with the more affluent economies? Unequivocal answers to these questions are not readily available.

The governments of the more developed countries, in order to protect their foreign loans and the investments of their citizens, help recipient governments to stay in power by strengthening their military and police forces. This arrangement leaves the large landowners, the military, the industrial and mining interests, the traders, and the government bureaucracy in firm control of a country. Any change, social, economic, or political, which threatens this power structure is deemed "subversive" and dealt with accordingly. Should a government come into power that attempts significant reforms, there is always a military coup at hand to remove it from the scene.

As a consequence of a mutuality of interest between the dominant power groups in the donor and recipient countries, substantial aid and indigenous resources have been used for construction of luxury hotels, apartments,and office buildings, and for obtaining luxury consumer goods and services, as well as for the exploitation of mineral resources and the establishment of capital intensive industries. In agriculture, the more affluent landowners have been the first to obtain the benefits accruing from the introduction of the high yielding varieties of rice and wheat.

However, foreign aid has undeniably contributed substantially to present and potential progress in some sectors of the economies of the recipient countries, including the agricultural sector. Most of the infrastructure projects, such as roads, dams, electric power generating and transmission facilities, and some of the education programs, such as the strengthening of medical, agricultural and public administration schools, have furnished a foundation for future economic and social progress.

Nevertheless, certain major aspects of foreign aid have helped create conditions that give little promise to dealing effectively with the need to advance a technology suited to small farms and with the need to create non-farm employment opportunities for a rapidly growing rural labor force. Insofar as aid is responsible for maintaining governments in power that are unwilling to carry through meaningful land tenure reforms or to devise a tax system which provides sufficient revenue to support really adequate education and health programs or to accept responsibility for the creation of sufficient employment opportunities in rural areas, then aid has been inimical to agricultural development.

Insofar as aid has contributed to an emphasis on the expansion of capital intensive industry in urban areas and has given priority to the larger landowners in programs to increase the output of food and export products, it has served to create islands of affluence, leaving the bulk of the people still with a traditional technology and at a subsistence level of well-being. A country with a dual society of this nature can never build a domestic consumption base to insure a full realization of its technological potential, either in agriculture or in industry. It leaves a major portion of its human resources untapped. Unfortunately, nearly every less-developed country is well on the way toward having a society in which those now at subsistence levels may remain there indefinitely while a small affluent segment will have all the advantages of both modern technology and feudalism.

There has apparently been massive lending and investment motivated by political and profit considerations, with too little attention paid to the prospective capacity of the recipients to earn foreign exchange. Already many recipients are experiencing difficulty in meeting debt and profit service. These difficulties will be compounded, should the "donors" succeed in their present efforts to induce a further massive expansion of lending and investing. Within a very few years the number of recipients unable to earn sufficient foreign exchange to meet foreign obligations will surely rise. Moratoriums and renegotiations will become habitual. Recipient currencies will be depreciated in relation to donor currencies. Official devaluations will become even more frequent.

Rising pressures to produce for export will distort the allocation of resources in agriculture, causing production to increase regardless of export prices. The terms of trade will worsen for the recipient, making still greater production for export imperative. More and more resources, which might have been used to produce for domestic consumption, must be allocated to produce for export as debt and profit service requirements grow. Food production may have to be sacrificed to produce exportable products. Existing land tenure systems will remain entrenched because they will most effectively produce surpluses for export.

Unless there are drastic changes in the concept and direction of foreign aid and in the strategy for achieving goals in the developing nations, the level of living of cultivator families will not be much improved.

It is intriguing to contemplate what might have happened if these poor countries with colonial and feudal backgrounds had been permitted to exercise a greater measure of responsibility for the development of their respective societies without external intervention, or, indeed, what could happen even yet if they should go more on their own.

A very minimal amount of loans and investments and a very minimal number of "technicians" from external sources would best serve the national interest of these countries. In discussing the contribution of aid to development, Mikesell concludes that "as a general proposition, external capital or aid is neither a necessary nor a sufficient condition for development. . . . By and large countries that are not making satisfactory progress, regardless of their per capita income, have failed to realize the potential returns from their own resources. What is required are policies and programs for mobilizing, adapting and reallocating those resources, including the training of human resources for the operations of a modern economy" [9].

There is also the principle of self-reliance and national pride in accomplishment. This principle has been sadly neglected. As Professor Brahamanand Prasad of Patna University has observed, "India has, at present, in the country capable engineers and technologists, trained both abroad and within the country, who could safely be entrusted to take up the work of development. In fact, a large part of this talent is either idle or underutilized. . . . It can be said that foreign collaborators and technology have exerted a depressing influence on the growth of self-reliance" [14].

The foreign aid needed by a developing nation is the kind that would enable its citizens to utilize their own natural resources, accumulate their own capital, and operate their own economy by themselves and for themselves exclusively, even though the process would be gradual over a considerable period of time.

Agricultural Price Policy in the Context of Economic Development*

John W. Mellor

AGRICULTURAL price policy is a means for influencing the development and allocation of resources to society's objectives of growth and equitable distribution of income. Formulation of agricultural price policy is complicated by the multiplicity of often conflicting functions that price performs, including: (1) allocation of resources between agricultural and nonagricultural sectors; (2) allocation of resources within agriculture; (3) generation of additional resources for growth, particularly capital; and (4) distribution of income amongst regions, sectors, and income groups [8, 9, 10].

Agricultural price policy is of particular importance with respect to income distribution because agriculture produces the consumer goods that comprise the bulk of expenditure by low income people [1]. Even though agriculture is primarily a consumer goods producing industry, agricultural prices affect capital formation by their influence on distribution of income, industrial profits, and government net revenues [1, 6]. With respect to efficient allocation of resources, it must be remembered that the personnel and structure for administering price policy are also scarce resources that must be allocated efficiently. This places an important restraint on choice of optimal price policy. Finally, the actual price policy chosen will reflect the state of knowledge concerning the various variables. Uncertainty regarding the effects and objectives of price policy will normally necessitate adoption of policy different from those which would be preferable under conditions of certainty.

Agricultural price policy delineated in this paper assumes three prime characteristics of a country's economy: (1) that it is a low income country, with a small capital stock, a small capacity to save, a small supply of administrative talent, limited administrative structures, and a small command of financial resources by government; (2) that the requisites have been met for moderately rapid technological change in agriculture with constantly shifting production functions and declining unit costs of production; and (3) that economic growth is proceeding, with rising real per

I am grateful to AID for financing this work, to various participants in the Prices Research Project for their research results, and to K. L. Robinson, B. F. Stanton, and W. G. Tomek for their critical comments on an earlier draft.

John W. Mellor *is professor of agricultural economics at Cornell University.*

capita incomes and shifts in the demand structure for agricultural commodities towards higher income elasticity of demand commodities.

Basis for a Price Policy

The price policy discussed in this paper is applied to the basic food grains—normally a small number of closely related commodities, relatively nonperishable and, for most countries, consumed largely in the domestic market. For these commodities, a set of support prices would be set annually, with emphasis on support of that year's harvest season prices. The support level would be determined by an appraisal of the current supply and demand situation—the support level normally varying inversely with the size of the crop. The level set would be modestly below the calculated suppy-demand balance price. The primary purpose of this policy is protection of farmers against market imperfections and consequent sharp decline in price below the normal supply-demand balance price. Announcement of the support level would be made somewhat before harvest time, but sufficiently late to enable a reasonably accurate estimate of the domestic supply for that year. Presumably, trade policy would give appropriate consideration to international price relationships. The Government would accept deliveries at the support price, such supplies often being sold at a seasonally adjusted price the same year, and occasionally carried over to later years.

This policy has four major assumptions. First, rapid agricultural development is based on unit cost-reducing technological change, which is more a function of public policy towards research, education, and such matters than of price policy. Inappropriate price policy may slow technological change, but the prime function of price policy is to meet problems resulting from technological change rather than to create technological change.[1] Second, compared to high income countries, the demand for agricultural commodities is less inelastic with respect to price, and the effect on farm incomes of given market price declines also is much less. Third, in the dynamic context of technological change and economic growth, the basic price problem for agriculture is one of year-to-year instability, a problem which is particularly great in low income countries where the operation of markets may be particularly imperfect.

The concern for year-to-year price instability in a context of development assumes significant market imperfections. The method suggested for setting the support level achieves little in a situation of perfectly functioning markets. However, despite competitive conditions facilitated by easy entry, a large number of participants and a high degree of market integration, there are substantial, difficult to remove market imperfections in low income countries, tracing from costly and uncertain transport facilities and lack of knowledge of crop size and storage stocks [7, 12]. There is a tendency for such markets to operate naively and for movement in one direction to accumulate. Particularly where technological change and economic growth are both new phenomena, one can expect sharp changes in supplies of particular commodities as new technologies affect first one and then another commodity and as demand shifts accompany rising incomes. Such shifts in supply and demand can result in substantial changes in prices which may be accentuated by market imperfections.

---

[1] Schultz has argued that agricultural production is impeded by "widespread underpricing of farm products and overpricing of agricultural inputs in poor countries" [15, p. 51]. Where such a negative policy has been followed, redress may be in order. However in situations in which such policies are often said to prevail, they apparently have not [11, 12]. In Taiwan they have prevailed, and agricultural development has proceeded rapidly anyhow [6].

Commodities to be Supported

Even supporting the prices of basic food grains runs the risk of exceeding the administrative, financial, and physical storage facilities available to government. The problem would be accentuated if prices of perishable commodities were supported as well. In addition, the complexity of setting suitable relationships among prices of various commodities increases substantially as the number of commodities increases. This will further strain the government's supply of analysts and administrators.

Basic food grains are the agricultural commodities for which the income elasticity of demand is the smallest. In the context of rapid technological change and income growth, resources should gradually be shifted away from these commodities toward the more income elastic agricultural commodities. There is a danger that limiting a price support program to food grains will channel resources towards rather than away from them.

It is logical to think that if the economy should be restructuring away from the basic food grains and towards the more income elastic types of agricultural commodities that a price support program might concentrate on the latter commodities. Unfortunately, the more income elastic commodities tend to be those that are relatively perishable and hence pose immense problems for the operation of a support program. Presumably, the most effective means by which government policy can improve prices for these commodities is through improved marketing facilities [4, 14].

Method for Determining the Support Level

It is proposed that the level of support be determined by estimate of the equilibrium price under the expected supply and demand conditions of the approaching year. Demand estimates may be based upon projections of population and per capita income, estimates of income elasticity of demand, and a measure of inflationary factors such as the money supply (see, e. g., [11]). Supply may be estimated either by sample observation or through projections taking into account changes in technology, inputs, and weather. If government capacity to support prices is weak and weather fluctuations large, it will be important to make the estimate close to harvest time. If weather fluctuations are unimportant or capacity to support great, little will be lost by setting prices even in advance of planting.

Cost of production should not be an explicit basis for determining the support level, partly because the context assumed is one of improving technology and hence declining unit costs[2] The basic incentive for expanding production is provided by declining unit costs, not rising prices. For similar reasons input subsidies are not recommended.[3]

The objective of the policy stated is not a constant level of agricultural prices. When favorable weather has provided a large crop, prices would be lower than when unfavorable weather has provided a small crop. In low income countries, the scope to expand consumption, even of basic food grains, through lower prices is greater than in high income countries. Further, real incomes of farmers tend to be higher with a large supply than with a small supply [10]. That is, of course, the opposite of the relationship expected in high income countries. The reasons for this reverse relationship are (1) demand is much less inelastic with respect to price in low income countries, and (2) a substantial proportion of basic food commodities are retained for home consumption and are not affected by a price decline incident to greater production. Of course, if demand is inelastic, those producers who sell practically all of what they produce may experience income changes inverse to level of production.

The Level of Support

If the objective of price supports is to protect farmers from market imperfections that drive prices below the supply-demand balance price, then the support price should be moderately below that price in order to allow the market to operate within reasonable bounds and to increase the probability that the policy can be administered.[4] There are two basic considerations in deciding how much below the supply-demand balance price supports should be set. First is the financial and administrative capacity to make support purchases; second, the degree of precision with which the appropriate price can be estimated. The lesser the capacity to make support purchases and the lesser the capacity to estimate the normal supply-demand equilibrium price, the greater the discount to be set for the support price; the greater the discount for the support price, the less helpful it will be to farmers. On the other hand, if the support is set so high that it cannot be maintained, confidence in the government's ability to support prices will be destroyed and susceptibility to sharp price decline increased.

---

[2] For a contrary view and an excellent, extended discussion of agricutural price policy see [5].

[3] For a fuller explanation of the logic of this, see [8]; for illustration of the effect of technological change on returns to inputs, see [2, 6, 13].

[4] There is a naive assumption here that economists set agricultural support prices. In practice, political processes may dominate. This argues for caution in initiating price support programs and for thoroughly considering other devices to achieve the same ends. Certainly, programs of improved transport and market reporting should be studied as supplements and alternatives to price policy for dealing with market imperfections.

Timing Announcement of the Support Level

Announcement of the support level just prior to harvest season has the advantage of allowing more accurate appraisal of the supply situation, particularly with respect to weather. For most farmers in low income countries, a constant price irrespective of weather effects on crop size will *increase* fluctuations in real incomes as compared with basic supply-demand equilibrium prices. Thus, a policy of setting prices prior to planting would normally provide less farmer real income stability than setting them just prior to harvest. The converse is the case for consumer real incomes.

Announcing the support level prior to planting is necessary if the objective is to cause an immediate reallocation of resources towards specified crops. This is unlikely to be the objective with respect to the basic food grains in a context of economic development and technological change in agriculture.

Supports announced prior to planting, followed by unexpectedly large acreage planted or unusually good weather, may place burdens on the government which it is not able to sustain. With a resultant sharp price decline, farmers would be even less willing to plan on the basis of government supports in the future. Recognition of this problem may require that supports established prior to planting be set at a level lower than would be justified by later information. This could form part of a useful two-stage setting of supports—a conservatively low level prior to planting and a potentially higher level prior to harvest. It is, however, doubtful if the preplanting price would have sufficient credibility to be useful. It is also doubtful if political processes would allow this degree of fine tuning.

An Alternative Context for Price Policy

The policy context in low income countries has often been quite different from that stated above. In this analysis, we have assumed general economic growth with rising per capita income and technological change in agriculture causing lower unit costs of production. While that has been the situation in Japan and Taiwan during their periods of rapid economic growth and it is a situation commencing in most Asian countries at the present time, it has not been the dominant situation in most Asian countries over the last decade.

A common context has been one of growing population, modest industrial growth, slowly rising per capita incomes, and a technologically stagnant agriculture reflecting the classical case of diminishing returns to increased inputs [8, 9]. Agricultural prices are certain to rise under these conditions unless the demand for agricultural commodities is artifically contained or unless imports of agricultural commodities are increased.

If demand is artifically contained through price controls and rationing, purchasing power will be shifted to commodities that use scarce foreign exchange or that shift domestic resources towards consumer goods production—in each case reducing growth in the capital stock [8, 9]. If imports of food are financed from foreign exchange there will likewise be reduced growth through declining availability of imported capital goods.

If agricultural prices are not contained by restraining demand or increasing imports, resources will be transferred from the nonagricultural towards the agricultural sector of the economy. Under conditions of technological stagnation in agriculture, those resources will be subject to diminishing returns, causing rising unit costs of production in the agricultural sector. Concurrently, rising money wages and agriculturally based raw material costs will retard growth in the industrial sector [1, 6, 9].

The dilemma is clear and not likely to be met by price policy alone. What is needed is a public policy that will bring about rapid technological change in the agricultural sector—the context set at the beginning of this paper.

Consumer Protection

The effect of decline in production on farm incomes is partially muted by higher market prices, even for low income farmers who retain a substantial proportion of what they sell. The full brunt of higher prices falls on low income urban consumers, with essentially no forces to offset the effect in the short run. Consumer welfare and political considerations may require a storage and price stabilization program that would not be justified from a production point of view.

In the longer run, the consumer welfare problem becomes a problem of industrial capital formation. Assuming initial equilibrium with respect to the urban labor supply, a sharp rise in the cost of living of the low income urban labor force will force higher money wages, a squeeze on business profits, and a reduction in the rate of growth of the industrial capital stock [8, 9]. Thus, on the basis of both welfare and economic growth, one can argue for programs to stabilize supplies and prices of basic food commodities to low income urban consumers.

Government controlled buffer stocks can meet the need of urban price stabilization. Alternatively, at lower economic cost and higher political cost, rationing can be introduced during periods of scarcity, with supplies purchased on the market and rationed at subsidized prices to low income consumers. Consumption of low income consumers who have more elastic than average demand would be maintained at a higher level than would otherwise be the case. In consequence, the market price would be forced very high to reduce consumption on the part of high income consumers with highly inelastic demand. Under these circumstances, governments would normally choose a system of deliveries at controlled prices to reduce the price of supplies to be rationed to low income consumers. Alternatively, total production could be sequestered by government and rationed to all consumers. This would probably require a larger bureaucracy than a program that relied on high free market prices to ration to high income consumers.

Discussion: Agricultural Price Policy in the Context of Economic Development

F. A. WILLIAMS

Admittedly, when one discusses a paper and begins to make reflections on it, one automatically tends to be in a quandary as to whether to concern himself with the real nature of the written product, provide a capsule summary, refer to some incidental description couched in its background, or to drift, so to speak, into a running description about the limits and boundaries of the work. To me, at least, it is axiomatic that I hardly know where to start; but I shall begin with a capsule summary and then engage in digressive and polemic expressions.

Professor Mellor's paper may be divided into four distinct parts: (1) an introductory statement, which embraces a definition of agricultural policy along with a delineation of the prime characteristics of low income economies; (2) the economics of price policy, including choices and the mechanistic rubrics of price supports, (3) alternative policy, and (4) consumer protection.

The paper has been done extraordinarily well in the context of his thesis. Many of the ideas, which at first appear to have theoretical and applied gaps, were somewhat explicitly liquidated in a second clause, paragraph, or sentence. Yet, I would say that any paper which deals with price policy for economic development in the less developed countries of the world, particularly in Asia and Africa, is bound to encounter for its author a problematic or indeterminate situation, for the field itself is underdeveloped. Mellor's paper did not say it implicitly, but *price policy itself must not only express an expansion in national income, but it must reflect an increase in the volume of purchases made by agricultural producers themselves.*

The heart of the paper, for the most part, rests in part two—the economics of price support policy in low income countries; however, attention will be given by this discussant in varying degrees to each part.

F. A. WILLIAMS *is professor of agricultural economics at the North Carolina Agricultural and Technical State University.*

The Paper's Introduction

Undoubtedly, Professor Mellor has well stated his belief relative to what agricultural price policy and its associated concomitants encompass. However, I am somewhat dubious as to whether he has not established or deduced an abstraction that does not entirely represent the various kinds of variables that agricultural economies have in his generalized low income nations.

In the first place, a disproportionately large number of these nations have within their boundaries at least three well-established agricultural systems: (1) a market or sales share of the economy, extremely specialized; (2) a totally subsistence section of the economy; and (3) a mixed agricultural system (specialized and subsistence). It may be that only a market economy lends itself to economic analysis, but any concept or theory on price support in the less developed areas must, of necessity, consider all forces within a given postulation, because each agricultural system has its own variables, including the impact of economic, demographic, cultural, political, and technological characteristics. Price policy that does not have accompanying measures designed to influence the number of entrants into agriculture may be self-defeating.

Furthermore, the paper seems to assume that a set of conditions exists in less developed nations, as in the more developed areas, where income will expand and purchases by farmers will also increase. Hence, in part one, the paper tends to suffer from the lack of empirically tested evidence to support the ideas set forth. Actually, this means that the paper's approach is largely deductive, with dynamic conditions as opposed to comparative statics; and, therefore, if an effective price policy is to be established from this discourse, it is not apparent, as it does not coincide with the experience of the discussant in a number of less developed nations. These nations will not have the sophisticated crop reporting mechanism for the implementation of the proffered price policy.

Economics and Mechanics of Price Support

Undoubtedly, this portion of the paper represents the heart of Professor Mellor's hypothesis on the theory of price support for less developed nations. It is in this part of his paper that our generalized tendencies seem to come to the fore with some sharp differences in point of view.

The paper limits agriculture price policy to food grains, which is a rather narrow concept, since there are a number of less developed countries with fiber and oil crops and animal products on a *sales economy* basis for both domestic and foreign markets, accompanied, therefore, with a less competitive market which would generate a higher income level in that it would provide for greater income elasticity.

Also, inextricably bound to this paper's stated policy is the observed fact that it does not leave room for the mobility of labor to sources of higher supply prices. Furthermore, this aspect of Mellor's paper does not seem to make it possible for the development of agribusiness types of industries as a corollary to the production of food grains. This would seem to be an appropriate development of markets based upon more elastic products. Also, early in the paper, the term *imperfect* needs more clarification, since a price support policy adds to the imperfections of a market economy in the classical context.

Moreover, it would appear that the paper has ignored entirely the American experience in supporting the production of basic crops. Perhaps this was overlooked because it is incorrectly assumed that a surplus of agricultural products seldom arises in less developed nations; but that is not the case with fiber crops in some of these areas of the world.

Incidentally, an inconsistency exists in a price support policy for the less elastic commodities, for this method will have price supports keeping resources allocated in these commodities rather than causing shifts to occur.

Another somewhat apparent weakness is that of supporting a maximum supply of food grains as opposed to a sliding scale of support with an optimum supply in order to free other resources for a hetero-development of the economy, making it possible for changes to become operative from year to year.

Furthermore, the paper indicates that the cost of production would not be a factor in the price support level based upon what occurs in the more developed countries; but, strangely enough, the cost of production would rise in the less developed nations due to the level of increase needed in capital inputs, especially in the short run, bringing higher costs and necessitating the consideration of new production costs as part and parcel of a support price. In other words, the state of the arts would largely determine the incentive for production. It is axiomatic that a price policy, as proposed for a less developed nation, may cause a slight rise in aggregate income while per capita income declines as more of the population will be forced to remain either in agriculture or enter into agriculture, thereby bringing into focus disguised unemployment or underemployment, which would not fulfill the function of the proper allocation of resources between agriculture and non-agriculture sectors of the economy. Consequently, the policy tends to over-allocate resources for agriculture in that it does no postulate a rise in the prosperity of urban areas.

The question to be answered is why induce a conceptualization that is purely oriented agriculturally, rather than for the economy as a whole. If the less developed countries are to progress with greater rapidity, economic models must be created which will make for total development rather than for a single sector that fails to develop a concept for a balanced economy. We must not accept the faulty assumption that agricultural output in food grains should take priority because there is apparent high demand for additional food and, therefore, imply that the greatest productivity of existing capital lies in agriculture. This approach will only lead to a higher rate of unemployment where there is already a scarcity of industrial enterpreneurship; but the idea is further complicated by the high ratio of dependents to producers found in African and Asiatic countries, thereby invariably minimizing any gains in per capita income.

Professor Mellor indicates the significance of timing in the price support level for these nations, I suppose, in order to minimize probable losses to governmental marketing boards. Prices that are not announced prior to production processes would not serve as an incentive for resource allocation in agriculture by holders of capital who are willing to make investments in agricultural productivity.

Alternative Context Patterns

In this section of the paper, Professor Mellor points out that agricultural prices will rise unless demand for agricultural commodities is artificially contained. Perhaps this is correct, but it is also a truth that purchasing power will rise under non-restraining policy where output is relatively stable and the anticipated shift to other commodities will not occur easily.

The real alternative does not rest in price controls and rationing for agriculture in the less developed countries, but the point must be reached where surpluses can arise, thereby creating a basis for investment so that employment opportunities may expand and keep pace with an excess population problem.

Professor Mellor leaves much to be said as to whether his price support contexts and alternatives follow logically from his basic assumptions relative to low income nations.

Also, in this portion of the paper, an implied assumption is present which indicates that agricultural production in the less developed countries is conducted under conditions of private property in land. An alternative in the Sudan is the Gezira Scheme, where the government either owns or rents the land and the net revenue is shared with tenants and–or owner-operators. Under this concept, prices for agricultural commodities are under the economic forces of competitive world prices.

It would appear that an admixture of prudent price policy on basic commodities, governmental monopolies, import duties, induced technological changes, and industrial expansion would enhance the trend for greater rapidity in economic growth. As pointed out by Professor Mellor, "these nations have a growing population, slowly rising per capita incomes, and a technological stagnant agriculture." Consequently, the dilemma cannot be resolved by a price policy rooted only in the output of food grains.

Consumer Protection

In the fourth and last part of the paper, I find myself in more agreement with Professor Mellor relative to the techniques which he would employ for protecting consumer welfare than in the previous three sections. Perhaps this is more important in a less developed country where there is a scarcity of nearly all resources than in a developed country where resources are generally in abundance and with consumer sovereignty running the gamut of elasticity of demand.

Even here, there is some doubt as to whether consumer welfare could be couched in economic class preferences because even in the urban areas of low income societies, incomes tend to equate with price increases for those with less elastic demand.

A Brief Concluding Statement

In conclusion, I have enjoyed both reading and discussing the paper presented by Professor Mellor. However, I must admit that a better title for the paper would have been something like, "Difficulties in Establishing Agricultural Price Supports in Less Developed Economies."

Discussion: Inducing Economic Development in Less Developed Countries

RICHARD PHILLIPS

It will be interesting to see what use, if any, future writers on economic development make of the contributions of this session. At least in part, the papers have emphasized policies and programs that the authors believe to be ineffective for inducing economic development. The Mellor paper recommends a very limited price support program to minimize interference with technological change in agriculture, improvement in marketing facilities, and other types of development. The Evans paper seriously questions the value to the developing countries of most foreign aid programs, particularly for achieving the stated goals of such programs. Both authors recommend reliance on programs to speed the adoption of agricultural technology as the main thrust for agricultural development. They see agricultural price policy and foreign aid as relatively ineffective tools that are often misused in attempting to speed economic development in the developing countries.

RICHARD PHILLIPS *is with Logistics Research, Inc.*

Agricultural Price Policy

The kind of agricultural price policy proposed by the Mellor paper would give food grain producers a price floor, primarily for protection against short-run price declines. If these price floors are set at levels somewhat below the equilibrium price just prior to harvest, as suggested, the price policy should have relatively little effect on the rate of economic development, either positive or negative. Certainly this kind of policy would cause less interference with the rate of development than many of those that have been tried in developing countries around the world. As the author points out, the policy would offer low income urban consumers no protection against sharply rising food grain prices.

If one accepts the basic assumptions of cost reducing technological change, rising real per capita incomes, and major imperfections in the markets for agricultural products, the policy recommended by Mellor should achieve the intended goals at a minimum cost to society. Presumably, other kinds of programs and policies would be used to overcome the major imperfections in the markets for farm credit, fertilizers, and other inputs, as well as in land tenure systems. In many developing countries, imperfections in these markets must be overcome before the assumption of cost reducing technological change can be realized.

The reader is still left with the question of whether some type of agricultural price policy could be devised for developing countries that would contribute directly to the rate of economic development. With the recent work toward applying input-output and other structural models to problems of development, it seems possible that the basic requirements for such a policy can be specified. The direct and indirect effects of agricultural policy through all sectors of the economy are complex, and the combined impact would vary from country to country. Yet well conceived structural models should be capable of predicting and measuring these effects.

Foreign Aid

There is much with which one can argue in the Evans paper, but many of the points are well taken. The conflict of such goals as economic growth and income distribution is a perpetual problem; and for many countries, the latter is overriding. The objectives of the "donor" country often do overshadow the objectives of the "recipient" country in foreign aid programs. One must agree that, at least within the present concepts of national and private property, there is no hope of closing the gap between affluent and poor countries.

Accepting the statement that *"development occurs when resources are allocated to produce the goods and services essential to human well-being in increasing quantities, and when the people in the greatest need are* *able to obtain and consume them,"* one can argue for an increasing amount of foreign technical and capital aid, even under the terms of the donor country. In addition to the value of the infrastructure projects recognized in the Evans paper, foreign capital and know-how are essential ingredients for effective resource allocation in agriculture and other private sectors in many developing countries. Perhaps the problems have not been with the volume of foreign aid, nor even with the conditions of the donor country, but with the practice of routing aid through "government-to-government" channels which could have been more effective through other channels. Government-to-government channels have provided reasonably effective foreign aid for roads, schools, hospitals, and other infrastructure developments, even with the changing political scene in many developing countries; but government-to-government foreign aid often has been far less effective in agriculture and industry.

There are other channels for routing foreign aid which are meeting some success in developing countries. The cooperative-to-cooperative programs are assisting in providing off-farm opportunities, as well as helping to improve imperfections in farm supply and product markets. The concept of domestic and foreign investors used in Iran is effective in mobliz-ing foreign private capital and know-how for industrial development, while maintaining control in Iranian hands. The same concept is now being applied to commercial agriculture in that country. In some cases, the direct entry by foreign corporations has materially contributed to economic development as defined in the Evans paper.

This writer is in full agreement that land and capital income, as well as labor income, are needed if low income subsistence farmers in developing countries are to reach satisfactory levels of living. However, this does not mean ill-conceived land reform programs to split up the larger farms and divide the spoils among the landless class. Many such programs have retarded the rate of technological change and economic development in agriculture. Egypt is a case in point. Large and small farms will coexist successfully in developing countries, just as they do in the affluent societies.

ANALYTICAL TECHNIQUES APPLICABLE TO DOMESTIC DEVELOPMENT

CHAIRMAN: DALE M. HOOVER, NORTH CAROLINA STATE UNIVERSITY

Tools of the Trade in Policy Decision—PPBS, a Case in Point*

WILLIAM B. LORD AND STEPHEN C. SMITH

FOUR years have passed since Lyndon B. Johnson announced the initiation of PPBS (Planning-Programming-Budgeting System) to guide and improve the decision-making process of the Federal executive branch agencies. In this paper, we examine the nature of PPBS, and the nature of the decision-making process that has evolved in one area—water resources. We shall examine in turn the kind of decision structure that PPBS seems designed to serve and the kind of decision structure that now exists in Federal water resource activities. We note a basic inconsistency between PPBS and the existing decentralized and pluralist decision process. Finally, we offer some observations as to how PPBS may be modified to both serve and improve that decision process.

I.

> As presently conceived, program budgeting contains an extreme centralizing bias. Power is to be centralized in the Presidency (through the Budget Bureau) at the national level, in super-departments rather than bureaus within the executive branch, and in the Federal government as a whole instead of State or local governments [3, p. 305].

Wildavsky's assertion accurately describes the implications of the information display scheme, the preoccupation with economic efficiency thus far embodied in benefit-cost analysis, and the spirit and application of PPBS in the MacNamara revolution.

Major budgetary decisions are to be made on a departmental level rather than at bureau or lower levels. The information displays in the Program and Financial Plan and the Program Memoranda are prepared to enable department level managers to make such decisions. Lower level

managers may find that new alternatives may emerge from the information they are required to send forward, but the aggregation of such information at higher levels may lead to program choices quite different from those that appear best at the lower levels.

Although they are not a part of the information format itself, techniques such as benefit-cost analysis are an important ingredient of PPBS. This paper is not the place for an extended discussion of benefit-cost analysis. It is relevant here, however, to point out that benefit-cost analysis, which has been called applied welfare economics, has been centrally concerned with the aggregate level of real national income (as the empirical surrogate for social welfare). Few economists would deny the importance of this concept as a desideratum in public decision making, just as few would deny that it is the sole desideratum. But benefit-cost analysis as it has developed has been preoccupied with national economic efficiency. Words of warning about over-concentration on this objective have not been taken too seriously [2, pp. 266–268]. By ignoring the politically important distribution aspects, benefit-cost analysis has not served the information needs of the many interest groups and lower level governmental units that participate in water resource decision making. The national taxpayer's interest in efficiency has been served but not the needs of each of us in our other roles in a pluralist democracy. The customary benefit-cost analysis has a particular relevance, albeit a partial one, to decisions of the President and the Bureau of the Budget but less relevance to bureaus, interest groups, industries, and state, local and special governmental units.

The questioning spirit of PPBS also favors centralization of decision making. Under Secretary MacNamara every recommendation was to be accompanied by supporting analysis, including a presentation of the major alternatives considered and the reasoning behind their rejection. A formal dialogue between decision-making levels was encouraged, but the decisions themselves were reserved to the Secretary. What other advantages or disadvantages this method of operation may possess, its centralizing tendencies can be utilized by an aggressive administrator.

II.

The field of water resources offers a good behavioral area to examine the effects of economic and technical concepts upon our institutional structure for making decisions. In this vein, the centralizing capability of PPBS has been noted, but two other technical concepts preceded PPBS and moved with force in the same direction. Benefit-cost analysis has been mentioned. Its emphasis on national income objectives grew compatibly with the development of macro economics as it became incorporated into the central body of economic thought. Thus, the economics profession has developed a set of analytical concepts that views the decision system from "the top down" and reinforces value judgments integrated by this system. In a similar fashion, basin-system analysis, which has been growing over a like period, reinforced these centralizing tendencies, since one of its objectives has been to internalize former externalities. These are not new concepts. They have been evolving for a long time, with their force becoming increasingly potent since their clear legislative articulation in the 1930's.

Our comments should not be misinterpreted to imply that these conceptual structures had no pre-existing behaviorial basis—they did, but time will not permit their detailing. A hint of their character can be noted, however, in the tracing of some elements of the decision pattern.

Water resources decisions still have deep roots that relate them to our system of property rights. This link, and the attendant role played by the property rights system in our economy, frequently create a discontinuity in defining decision problems and their solutions. Approaching the decision structure from this perspective, the view is from "the bottom up," and in contrast to the previously noted "top down" vista.

The "bottom up" approach is a different system, held together by a different set of logical threads tied to different objectives. The articulation of this system and its examination on its own terms have been infrequent. Most studies have applied the "top down" logic to the "bottom up" facts and have produced large "disparities" between objectives and accomplishment.

Our property system has led to a pluralistic system of decision making involving many individuals, each with his own objectives, participating in a highly decentralized decision process. Economic returns to the individual come from at least two sources: (1) the return from privately producing a product or a desired service for market, and (2) current and prospective rents, deriving from power over property. By the turn of the century, however, economic, physical, and political realities were bringing home the existence of externalities to the individual and the necessity of group action to partially internalize costs and returns to water development. To achieve the necessary scale, a variety of organizational structures and combinations were utilized. These ranged from private associations and companies, local districts, and units of government, to such Federal organizations as the Corps of Engineers, the Bureau of Reclamation, and the Soil Conservation Service. Local interest groups bargained *through* these Federal agencies to achieve their objectives. This Federal-local relationship, in turn, created the political backing necessary for the establishment and maintenance of the Federal agency structure. The Federal decision structure was not an abstraction, but an organization to distribute funds in certain ways.

At the national level these "local" projects were sifted and judged with respect to (1) a given level of the Federal budget, (2) whether the budget should be larger or smaller, and (3) when each project should start. They came up through the system largely on the basis of their own "merits" and backing to accomplish a local purpose. Federal criteria were not maximizing or optimizing in character, but more in the nature of a minimum standard. In any given year, competition from other desired projects played a role. Also, the relationship to obtaining or withholding services in other fields of endeavor was taken into account in a very limited and implicit way.

This community approach to Federal investment fit the Congressional model. Pluralistic decision making, however, came under pressure with the recognition of new and larger externalities and as a result of a vast amount of construction. Benefit-cost analysis had expressed a Federal interest by setting a "minimum standard" for screening projects, but the agency-local interests were still paramount. Basin analysis and management was attempting a new integration of the externalities from individual projects, and PPBS required the formulation of national objectives *within* the bureaucracy. All of these forces have been and are revealing the disparateness of objectives and the fact that there are serious limitations under present day conditions to the project by project approach. Likewise, the realization is growing that the identification of objectives by a single bureaucratic process or pronouncing them "ex cathedra" by a professional elite is neither adequate nor appropriate.

III.

The major direct effects of most Federal water resources program decisions are "local," and the public they serve is limited. To be sure, all taxpayers share minutely in paying construction costs under present cost-sharing rules, but the other impacts of each project (or new program) decision on the general taxpayer are likely to be slight by comparison with its impact on those who are its direct beneficiaries or who bear its external costs. Even the large basin projects are local in impact by comparison with other Federal programs in such fields as defense, foreign relations, taxation, health, urban affairs, civil rights, aviation, and education. Indeed, it is their pronounced local or regional nature that has made water resource projects the objects of such intense Congressional interest.

The national interest in Federal water resource programs has several aspects. The first of these stems from the various national goals or objectives, which the Federal government is attempting to achieve but which may or may not be considered at the regional or local level. Historically, such objectives as developing the West, conserving the soil, and providing a free system of navigable waterways have often been cited in support of water resource proposals. Critics have charged, rightly, that objectives of this kind are often employed to rationalize the self-interest of user groups. One of the salutory effects that may be expected to follow the introduction of PPBS is the devotion of increased critical attention to national goals and objectives. Both policy makers and analysts will be defining objectives in operational terms, questioning their relevance, examining the actual consequences of attaining them, and continually reformulating them in the light of experience. Objectives such as reducing personal income disparities and minimizing environmental deterioration are already achieving a status comparable to the more traditional objectives mentioned above.

Economic analysis can be helpful in the examination and redefinition of Federal program objectives. The externality concept is central to this effort. A national interest justifying Federal participation in decision-making and, possibly, cost-bearing may be defined whenever a regional water resource program or project seems likely to confer major benefits or costs upon parties outside the planning region. In such cases Federal participation can help to internalize the externalities and produce solutions that are more desirable socially.

A second aspect of the national interest in Federal water resource programs, national economic efficiency, arises primarily because Federal funds are used. The traditional role of the benefit-cost ratio, however imperfectly it may have been computed in some cases, has been to prevent the flagrantly inefficient use of Federal funds. The proper role of the national economic efficiency criterion in water resource program evaluation has been perceptively discussed recently by Castle and Youmans [1, pp. 1660–1665].

A third aspect of the national interest, and one which also stems from the use of Federal funds, is distributive in nature. Our national political system is vitally concerned with the distribution of Federal spending among the various states and congressional districts. Local projects, such as those in the water resources field, constitute an important part of this congressional rewards and penalties system. PPBS can contribute to the evaluation and improvement of this system by revealing the nature and extent of the resultant distributive changes and thus provide a measure of some of the costs of the system.

This suggests that the complex and decentralized decision-making system that has evolved through water resources development may more effectively recognize the extent and limitations of interests than does the decision-making system implied by PPBS, as it has developed in the area of national defense. If we do not wish to make water resources decisions in a centralized and hierarchical manner, PPBS had best be modified to effectively serve a decentralized decision-making process, for the weight of information and analysis is great and its effects on decisions will not be denied, however imposing the inertia of the existing system may now seem to be.

We conclude, then, that at the Federal level PPBS should be directed toward such Federal objectives as alleviating poverty and protecting the environment. However, a basic Federal decision appears to be the distributive one, and this is consistent with current political decision making in this area. Economic analysis in PPBS should show clearly who gets what and at whose expense for each proposed project. The Federal PPBS information display should focus on the allocation of Federal funds among the various regions, states and river basins. The rate at which Federal funds would be provided to each planning unit would then be determined at the national level. Water resource programs could be compared with and aggregated with other Federal programs to make such distributive effects more visible and subject to greater overt political attention.

While the rate of Federal spending in each region for water resource projects (and possibly other functions as well) would be determined at the national level by the President and the Congress, how that money was spent would be left for local determination, subject to nationally established constraints, such as environmental degradation, national economic efficiency, and, possibly, personnal income distribution. If given a limited amount of Federal funds, local interests might be more discriminating in their choices as to how to spend. Wider competition and bargaining at the local level could eliminate many wasteful and ineffective projects that now survive for want of local opposition.

The kind of PPBS we have proposed relies heavily on river basin planning for both information and decisions. Programs would be regional rather than national ones. They would be developed at the regional level (as has been happening in California and Texas). Federal participation in program planning would occur only for two reasons: (1) because Federal or multi-regional interests were affected, or (2) because Federal funds were employed. In the first instance, that of externalities, joint decision making and bargaining between regional and Federal representatives is required. The PPBS information display should show the nature of the externalities in order to facilitate this process. In the second instance, that of Federal cost-sharing, the essentially Federal decision concerns the rate of spending in each region. Both the President and the Congress could well concentrate upon this decision if the program content decisions, which are not primarily matters of Federal concern, were not forced upon them. The information provided by PPBS can serve to pose the proper questions and illuminate the choices that can best be made at each level of decision making.

Estimating the Effects of Resource Development Programs on Regional Employment

B. R. EDDLEMAN

MANY variables interact to determine the pattern of employment changes occurring within an area. Changes in investment levels that shift the supplies of critical resources often occur concurrently with changes in the demands for products, supplies of other resources, firm production possibilities, and the number of firms. Each of these separate types of changes can have a substantial effect upon labor employment. A continuing problem is how the relationships among these variables can be identified and taken into account in attempts to assess the separate employment effects of resource development programs. An important element is the consideration of how equilibration in product and factor markets is affected by programs designed to change the supplies of resources and, in turn, how changes in product and factor prices affect the level of output and resource employment within the recipient area. A general approach to this type of problem has been suggested by Tolley and Schrimper [3, p. 115], and Schrimper [1; 2, p. 141]. Their approach simultaneously considers aggregate and micro adjustments in product and factor markets.

In the first part of this paper, we will consider a theoretical framework for determining the separate effects of resource investment programs on changes in regional employment of labor. This model is a special case of the more general formulation by Tolley and Schrimper and is a variant of the regional adjustment model developed by Schrimper [1]. The second part of this paper will be directed to a discussion of possible alternative empirical investigations of the relationships suggested by the model.

Regional Employment Adjustment Model

There are three basic types of components in the regional model of adjustments. These are: (1) factor demands of firms in individual types of industries, (2) aggregate product demand and factor supply functions, and (3) the number of firms in the different industries. Exogenous changes in any of the components can have substantial effects on employment in a region because of the interaction among the various functions. This interaction operates primarily through changes in the prices of products and factors, which are determined at the aggregate level but have an important impact on output and input decisions made by individual firms. These latter decisions may result in additional changes at the aggregate level leading to

---

B. R. EDDLEMAN *is associate professor of agricultural economics and associate agricultural economist in the Experiment Station at the University of Florida.*

still further price adjustments. According to the model, equilibrium exists when all product and factor prices are consistent with their total demands and supplies.

For most areas, several but not all product and factor prices might be realistically assumed to be fixed, since adjustments within the area would not be likely to have a perceptible influence on the total markets for these commodities. Feedback effects associated with adjustments would operate primarily within factor markets since nearly all product prices, with the exception of those products produced for local area markets, would be largely exogenous to an individual area. Therefore, in the model, the product demands and the supplies of all but the nth factor are assumed to be perfectly elastic for an area in which r different types of industries exist and produce m different kinds of products with n-m different kinds of factors. Firms within each of the r industry groups are assumed to have similar production possibilities and be operated by basically the same type of entrepreneur.

Under these assumptions, and denoting base quantities of the nth factor as $Q_n{}^0$, the proportional change in the aggregate demand for labor (i.e., employment) in an area can be expressed in the following form:

$$
\begin{aligned}
(1)\qquad \frac{dQ_L}{Q_L} = & -\frac{\bar{\alpha}_{Ln}Q_n{}^0}{Q_n{}^0(\eta_{nn}-\bar{\alpha}_{nn})}\sum_{f=1}^{t}\tau_{nf}\frac{dX_f}{X_f} \\
& + \sum_{j=1}^{m}\left[\bar{\epsilon}_{Lj}+\frac{\bar{\alpha}_{Ln}Q_n{}^0\bar{\epsilon}_{nj}}{Q_n{}^0(\eta_{nn}-\bar{\alpha}_{nn})}\right]\frac{dP_j}{P_j} \\

$$

where

Q_L = total quantity of labor demanded in the area

$Q_n{}^0$ = total quantity of the nth factor initially utilized

$\bar{\alpha}_{Ln}$ = weighted elasticity of demand for labor w.r.t. the nth factor price (weighted by the proportion of total demand for labor attributable to each industry)

$Q_n{}^0(\eta_{nn}-\bar{\alpha}_{nn})$ = difference in the quantity of the nth factor that would be demanded and supplied at a price 1 percent from its equilibrium value

η_{nn} = elasticity of supply for the nth factor w.r.t. its own price

$\bar{\alpha}_{nn}$ = weighted elasticity of demand for the nth factor w.r.t. its own price (weighted by the proportion of total demand for the nth factor attributable to each industry)

τ_{nf} = elasticity of supply for the nth factor w.r.t. the fth shifter of factor supplies (X_f)

$\bar{\epsilon}_{Lj}$ = weighted elasticity of demand for labor w.r.t. the jth product price (P_j)

$Q_n{}^0\bar{\epsilon}_{nj}$ = change in the demand for the nth factor resulting from a 1 percent change in the price of the jth product

$\bar{\epsilon}_{nj}$ = weighted elasticity of demand for the nth factor w.r.t. the jth product price

$\bar{\alpha}_{Li}$ = weighted elasticity of demand for labor w.r.t. the ith factor price (P_i)

$Q_n{}^0(\bar{\alpha}_{ni}-\eta_{ni})$ = difference in the quantity of the nth factor that would be demanded and supplied at initial equilibrium price after a change of 1 percent in the price of the ith factor

$\bar{\alpha}_{ni}$ = weighted elasticity of demand for the nth factor w.r.t. the ith factor price

η_{ni} = elasticity of supply of the nth factor w.r.t. the ith factor price

$\bar{\gamma}_{Lh}$ = weighted elasticity of demand for labor w.r.t. the hth shifter of firm production possibilities (Z_h)

$Q_n{}^0\bar{\gamma}_{nh}$ = change in the demand for the nth factor resulting from a 1 percent change in the hth shifter of firm production possibilities

$\bar{\gamma}_{nh}$ = weighted elasticity of demand for the nth factor w.r.t. the hth shifter of firm production possibilities

q_{Lk} = quantity of labor demanded by a firm in kth industry

q_{nk} = quantity of nth factor demanded by a firm in kth inudstry

dN_k = change in the number of firms in the kth industry

The above equation indicates how changes in the exogenous shifters of factor supplies, product demands, firm production possibilities, and the number of firms affect the demand for labor in an area. All of the coefficients for the first four types of shifters relate to the effects emanating from existing firms in the area, whereas the final term takes into account the effects of shifts in the number of firms. The impact of each of these shifters on changes in employment occurs either through a direct shift in the demand for labor or through changes in the prices of factors with other than perfectly elastic supplies that affect labor demands.

One term which is present in each of the coefficients of the exogenous shifters is $Q_n{}^0(\eta_{nn}-\bar{\alpha}_{nn})$, which gives a measure of the amount by which the quantity demanded of the nth factor would differ from the quantity supplied at a price 1 percent from its equilibrium value. Thus, the absolute value of this term represents the change in demand or supply for this factor that would be consistent with its price changing by 1 percent. The reciprocal,

$$\frac{-1}{Q_n^0\ (\eta_{nn}-\bar{\alpha}_{nn})},$$

can then be interpreted as the approximate percentage change in price for each unit change in demand or supply of this factor resulting from exogenous shifters in the model.

The first term in equation (1) indicates the effects of specified changes in the supply of the factor assumed to be other than perfectly elastic for the area. These types of changes would be expected to affect the price of the *n*th factor and thereby influence the demand for labor. For example, if the supply of this factor increased in an area as the result of a planned program of resource development, its market price would be expected to fall. Such a change could act as an incentive for existing firms to substitute the factor for labor to the extent possible within given production techniques. In this case of technical substitutes, the net effect would be a decrease in the demand for labor by existing firms in the area, *ceteris paribus.* A negative value for the $\bar{\alpha}_{Ln}$ terms would indicate technical complementarity between labor and the *n*th factor. Thus, the direction and magnitude of changes in the demand for labor due to a given change in the supply of the critical factor would vary among areas in proportion to the algebraic sign and the size of the $\bar{\alpha}_{Ln}$ terms. If any of these terms were zero, it would indicate that the change in the critical factor's supply had no effect on employment changes in the area's economy. This would mean that either the area's firms did not use this factor or their labor demand functions were perfectly inelastic. In general, a given change in the supply of the *n*th factor would result in larger changes in employment for those areas comprised of industries whose labor demands were more responsive to changes in the price of the *n*th factor or which used larger amounts of the *n*th factor. The effects of any change in the supply of the *n*th factor would also be greater for areas in which the demand and supply of the factor were more inelastic, which would be represented by a smaller absolute value of $Q_n^0(\eta_{nn}-\bar{\alpha}_{nn})$.

The effects associated with the remaining exogenous shifters are similar in that the coefficients are composed of a direct and indirect response in labor demands. The employment change associated with changes in product prices, indicating shifts in product demands assumed to be perfectly elastic, is represented by the second term in the equation. Changes in product prices would be expected to change net returns of existing firms and thereby serve as an immediate incentive for output to change and, thus, for direct shifts to occur in labor demands. This effect is taken into account through $\bar{\epsilon}_{Lj}$, which represents the elasticity of demand for labor with respect to the price of the *j*th product. As output from existing firms changed, the demand for the *n*th factor would also shift, resulting in a change in this factor's price. The price change for the nth factor would result in an indirect shift in labor demands through the $\bar{\alpha}_{Ln}$ term. In the case of substitutes, an increase in the price of a product would be expected to increase the demand for labor indirectly through an increase in the price of the nth factor. Thus, the direct and indirect effects of a product price change would operate in the same direction on labor demands. The indirect effect would tend to be larger for areas with larger values of $\bar{\alpha}_{Ln}$ and $Q_n{}^0\bar{\epsilon}_{nj}$ or smaller absolute value of $Q_n{}^0(\eta_{nn}-\bar{\alpha}_{nn})$. For those industries in an area that did not produce any of the product whose price increased, the employment effects would be only in terms of the resulting price change for the critical factor.

Changes in the prices of factors, representing shifts in the factor supplies assumed to be perfectly elastic, would affect employment in much the same manner as changes in product prices. Higher factor prices would decrease the net returns of existing firms in an area and thus serve as an immediate incentive for firms to substitute other factors for those experiencing increased prices. As firms respond to the new situation, the demand for labor as indicated by the direct component, $\bar{\alpha}_{Li}$, would increase. Similar adjustments would occur in the nth factor market, resulting in an increase in the nth factor price. The latter change, represented by the indirect component, would tend to complement the initial adjustments associated with the direct effect unless the supply response of the nth factor was of such magnitude as to offset the effects of the increased demand for this factor.

It is more difficult to indicate the direction of change in employment resulting from exogenous shifters affecting firm production possibilities than for the other types of shifters. Shifts in Z_h could result in increases or decreases in the demand for labor directly, as well as for the nth factor, depending upon how each of the components of the coefficient were affected. In the absence of any inherent labor-saving biases, if the price of the nth factor increased due to an output-increasing change in production possibilities, the direct and indirect effects would complement each other. The demand for labor would be expected to increase. For price decreases of the nth factor, however, the two components would operate in opposite directions. The actual direction in which employment would change depends upon whether $\bar{\gamma}_{Lh}$ is larger or smaller than $\bar{\alpha}_{Ln}Q_n{}^0\bar{\gamma}_{nh}/Q_n{}^0(\eta_{nn}-\bar{\alpha}_{nn})$.

Employment changes resulting from increases in the number of firms occur in a manner similar to the changes associated with product prices. This results from the positive relationship between the demand for labor and changes in the prices of critical factors. The entrance of new firms would directly increase the demand for labor and would indirectly increase labor demands by bidding up the prices of critical factors.

Empirical Investigations Suggested by the Model

The above discussion emphasized the interrelatedness of programs designed to shift the supplies of critical resources in an area and changes in other economic phenomena that affect the markets for these resources. This section includes a brief discussion of the general nature of two types of empirical studies under way to assess the revelance of the framework in explaining employment changes among and within areas in Florida.

Generally, the same types of independent variables are being developed for inclusion in each of the empirical investigations, whether it is a cross-sectional single equation or a time-series simultaneous equation system of analysis. These variables consist of changes in variables, observed either annually or between census dates, which are assumed to be analogous to the effect of differential changes in particular exogenous shifters. For example, percentage changes in farm commodity allotments, total current education expenses, total cumulative highway construction investments, ACP payments for farmland development, and total cumulative construction expenditures for water resource development are used to represent changes in important factor supplies in the areas. As an alternative to education expenditures, percentage changes in hired wage rates are used to indicate possible differences in the rates of change in the supply of labor. Weighted indexes of changes in product prices and output per man-hour are used to represent exogenous changes in product demands and firm production possibilities, respectively. The actual change in firm numbers is used to explain variation in employment due to decisions of firm operators to enter or exit from production within areas. Measures of changes between 1959 and 1964 in these variables for each major type of manufacturing industry and for agriculture are being developed for every county in Florida. Annual estimates since 1947 of these variables are being developed for a region composed of thirty-seven countries in the northern and western portion of the state.

In the first approach, a two-sector adaptation of the model composed of the agricultural and manufacturing sectors of each county is being used to estimate the relationships set forth in the theoretical discussion. The linear relationship between percentage changes in total employment and measures of the various exogenous shifters described above provides the basis for an investigation of the extensive variation in employment changes between 1959 and 1964 among counties in Florida. Two separate multiple regressions are being estimated with this data. One regression includes all of the independent variables associated with the specific shifters. Another regression is a special form of the first type and includes only the variables whose coefficients are significantly associated with the changes in employment based on the results of stepwise regression procedures. A comparison of the estimated coefficients of the exogenous shifters from these regressions would indicate the specific types of variables (i.e., shifters of factor supplies, product demands, firm production possibilities, or changes in firm numbers) that explain the largest proportion of total employment variation.

The above type of analysis provides some insight into the relative importance and effect of changes in each type of shifter on employment variations among areas. However, a single equation analysis cannot give an accurate picture of the interrelatedness of the employments among industries within an area, for it tends to aggregate out of existence the elements that produce change in an economic system. For this reason, a different approach based on the same general conceptual framework expressed in the regional model of adjustment is being used to examine employment variations among industries for the multicounty region.

With only minor modifications, the general relationships of equation (1) provide the conceptual framework for analyzing proportional changes in the demand for labor within a given industry. By replacing the weighted elasticity terms in the coefficients of the exogenous shifters with the specific elasticities for the given industry and eliminating the summation over all industries, the dependence of employment changes in an industry on the exogenous shifters of the model may be expressed. For example, in the first term of equation (1), $\bar{a}_{Ln}$ would be replaced by α_{Lnk}, the elasticity of demand for labor in the kth type of industry with respect to the nth factor price, and $\bar{a}_{nn}$ would be replaced by α_{nnk}, the elasticity of demand for the nth factor in the kth industry with respect to its own price. The resulting equation after making all of these substitutions in the coefficients of the shifters would reflect the dependence of proportional employment changes in the kth type of industry on given changes in the exogenous shifters in the model.

Using time series data for the dependent and independent variables, separate multiple regressions can be estimated for each major type of industry in the multi-county region. While the findings of such an investigation have considerable value for evaluating the effects of the various types of shifters on employment changes in the specific industries, structural equations would treat far more adequately the effects of the interrelatedness of the employments among industries.

Such a structural or simultaneous equations approach to the study of the region may not reveal all of the economic mysteries and the future of the region. However, these equations, when properly solved for their coefficients or parameters, do delineate the regional economic structure and provide information about it as can no other approach. This information is in the nature of statements about the quantitative properties of the various variables that were theoretically specified and joined together statistically to portray the economy of the region. Such knowledge about the quantitative properties may be tied in with other quantitative methods, such as input-output analysis, and with qualitative information to make possible the best judgments about the future of the region.

Concluding Remarks

The attempt in this paper to devise a framework for evaluating the separate employment effects of variables affecting the demands and supplies of factors in a region is motivated by an interest in finding a fairly comprehensive delineation of a regional economy and evaluating the effects of resource development programs on this economy. Such a delineation must be in the realm of the measurable, and the values measured must reflect both interdependency and independency of the economic variables used. Employment by industry has been suggested as the variable to be explained. The explanation of how employment is formed and how it varies leads to a useful structural description of a region. To be sure, the value of employment varies by regions and varies from industry to industry within regions. Consequently, its effect upon the region varies by industry. It is this variability that the structural system of equations picks up more efficiently than does any other method of analysis. A useful delineation of a region and the factors behind its behavior and development can be derived from a limited set of equations so long as the interdependencies are established and measured.

Estimating Contributions of Natural Resource Investments to Objectives in Regional Economic Development*

W. B. BACK

MY principal purpose is to assess the status of methods for estimating contributions of Federal water resource development projects with respect to regional economic objectives. Emphasis is upon problems experienced both by the Federal agencies and by those with responsibilities for assisting in economic evaluation of the projects.

Two theses underlying this paper are: (1) Appropriate procedures in benefit-cost analysis, as applied to regions, require a foundation in relevant concepts and theories of regional economic development; and (2) efforts to develop methods for estimating the more dynamic effects of water projects should be preceded by the development of defensible measures for the less dynamic effects.

Objectives of Water Resource Investments Relating to Regions

A recently released report of a special task force of the Water Resources Council advocated measurement of effects of water projects in terms of four sets of "national" objectives—national income, regional development, environmental, and well-being [5, pp. 16–25]. Regional development objectives included increased regional income, increased regional employment, improved regional economic base, improved income distribution within the region, and improved quality of services within the region. The expressed regional development objectives are not mutually exclusive; if values are assigned to each objective, there is a possibility of multiple counting of benefits by the agencies. This danger of multiple counting is accentuated when several agencies claim benefits to projects within the same region and interregional or interindustry distributional effects are ignored. A view apparently taken in the task force report was that water projects could be designed to accommodate any of a large number of combinations of national and regional objectives [5, pp. 72–73]. I wish to challenge this view.

In our optimism about beneficial economic effects of water projects, we often neglect the limits imposed by their physical purposes—flood control,

W. B. BACK *is agricultural economist with the Natural Resources Economics Division of the Economic Research Service, USDA.*

navigation facilities, irrigation, water supplies, power, etc.—and the highly functional nature of the planning necessary for their achievement. The limited scope and content of physical objectives—for example, usually what can be obtained by a system of reservoirs in a watershed or river basin—suggests that water projects may be inefficient or ineffective as public instruments for achieving many of our major economic objectives, including those for regions. I suggest also that the highly functional nature of these purposes severely limits management of the indirect effects by water project designers. The failure to fully and explicitly recognize such limitations of water projects could deter public consideration of more relevant programs and policies for attacking our major economic problems.

I propose that we restrict ourselves to three dimensions of regional development; namely, (1) increase in aggregate income within the geographical area designated as the region, (2) increase in income of those people within the region who fall in the lower income classes nationally, and (3) increase in efficiency in the use of the region's resources. Parallel views of regional development are discussed by Leven [2, pp. 1–12].

An increase in the aggregate income of a region is the objective sought by those identified by Leven as the self-interest group. Proponents of the second and third objectives mainly are interested in national rather than strictly regional (self-interest) economic objectives. However, these also are objectives in regional economic development because each relates to levels and distribution of income of people within a region.

The task force does not adequately distinguish or relate three types of income distribution: geographical, within-region personal, and national personal. Also, the sharing of benefits and costs of water projects permitted by law apparently was equated with a national objective in income distribution [5, p. 24]. In my view, national personal distribution of income is the central consideration in any national objective about income distribution. Other types or attributes of income distribution are relevant considerations only to the extent they affect the national personal distribution. One possible consequence of the failure to distinguish types of income distribution is the implication that projects built in economically depressed or low income regions automatically contribute to a national objective of achieving a more equal distribution of personal income. This implication occurred in the volume by Maass and associates in the discussion of trade-offs between national economic efficiency and regional income redistribution [3, ch. 2]. It now is apparent that direct farm program benefits going to our lowest income states often accrue mainly to the more affluent people both within those states and in the nation. The beneficial effects of water projects in low-income regions could be distributed in a similiar way.

Appraisal of a Regional Orientation

We now turn to some issues, activities, and experiences relating to effects of projects upon regional economies Up until about a decade ago, the principal concern of economists about water resource development was whether agency practices in estimating effects of the projects were consistent with criteria for increasing national economic efficiency. This still is a major concern. However, beginning with Senate Document 97, published in 1962, official Federal policy was to encourage evaluation of projects in terms of a number of objectives, including regional economic development. Agency practices in benefit-cost analysis did not change drastically in response to the new policy—in fact, major reorientations in agency practices since 1962 have occurred only in the Corps of Engineers' proposed water resource development projects in Appalachia, and these practices were more in response to the interpreted goals of the Appalachian Regional Development Act of 1965 than to SD-97. Nevertheless, the procedures developed by the Corps threaten to become a part of the standard operating procedures of all agencies and for all regions; and, because of that threat, this brief account and assessment is limited to some notions underlying these practices.

The central element in the proposed procedures is an assumed expansion effect due to the projects. This is a new kind of secondary effect—not "stemming from" or "induced by," as defined in the Green Book, and not a multiplier effect relating to regional export base theories or interindustry analysis. Rather, this new creature arises mainly from a projected expansion of primary or user benefits of water project services consistent with the interpreted goals of the Appalachian Regional Development Act. If the goals of the act are assumed to be (1) rates of regional development consistent with achievement of per capita personal incomes of people in Appalachia equal to that of people in the rest of the nation by the year 2020, and (2) job creation within Appalachia at rates necessary to employ the existing labor force and the natural increase thereof, then something phenomenal in the way of added economic activity within the region would be required within the next 50 years.[1] With three additional assumptions, all of this expanded economic activity net of associated costs of private capital investment could be attributed to the water resource projects. These assumptions are: (1) Investments in water resource development are perfect complements to the aggregate of all other investments, public and private, necessary for achieving the goals of the act; (2) the public component of these investments will be made regardless of the amount invested in water resource development; and (3) the private component will be made if the water resource projects are built. The assumed fixity in relation between proposed investments to develop water resources and other investments is as absolute as is the assumed necessity for accomplishing the goal of the act. The two become related imperatives.

---

[1] These correspond approximately to the first category of goals of the act, as discussed in the main report of the Office of Appalachian Studies [6, pp. IV–4 and IV–5].

One could grant that if expansion in economic activity within Appalachia must take place in locations specified by the Corps of Engineers—i.e., in the vicinity of the proposed water projects—development of some flood protection and industrial water supplies may be necessary. However, this approach ignores the possible existence of alternative locations within Appalachia for expanded economic activity that are not hampered by water supply or flood hazard problems. Also, even if water resource problems were the kind of obstacles supposed by the Corps, the basic approach assumes away the possibility of the existence of even more important obstacles to the economic development of Appalachia in accordance with the assumed goals of the act.

Most of the major ideas for the Corps approach in evaluating water projects in Appalachia were provided by Spindletop Research, Inc. [4].[2] In turn, Spindletop claimed a major source of their ideas was the unbalanced growth doctrine as presented by Hirschman in his discussion of investment for economic development in underdeveloped countries [4, phase 1, pp. 12–15]. This doctrine states that, in a growth process, sectors of an economy advance unevenly, and this very unevenness is the source of investment incentives underlying growth. It is a conception of growth arising from disequilibria—a seesaw produced by excessive investment by some sectors (and subsequent catching up and "over-investment" by the other sectors). As applied to public sector investment for economic development, the implication of the theory is to choose those investments with the best prospect of creating external economies (or investment incentives) to the private sectors. Hirschman sets forth a clear warning about the possibility of lack of success of some public sector investments in some locations within a country in inducing private sector investments [1, pp. 92–95].

The Spindletop group seemingly interpreted Hirschman's unbalanced growth theory negatively—that lack of investment in particular sectors of an economy acts as a "bottleneck" or near absolute deterrent to further development. This, along with the implied complementary relations among investments, is the basis for the ring of authority in the Corps' expression of the necessity for particular water resource projects. Although this "bottleneck view" of the unbalanced growth doctrine, I believe, in erroneous, the more serious error was an application, without modification or adjustment, of the unbalanced growth theory to an economically depressed region, such as Appalachia, within the United States. Growth is less geared to a larger economic setting in an underdeveloped country than in an underdeveloped region such as Appalachia. Urban-industrial development within a single region must compete with urban-industrial development elsewhere in the national economy. My hypothesis is that all of the proposed public investments specified in the Appalachian Regional Development Act, if made, would not eliminate this comparative disadvantage of the region for urban-industrial development.[3] In partial support of this hypothesis, I suggest that most of the instruments provided by the act long ago were available or were used in the Tennessee Valley portion of Appalachia, yet that area does not appear to be developing at the rate necessary for it to catch up with the rest of the nation in per capita incomes within 50 years. In fact, according to census reports for 1960, the percent of the families in Tennessee with incomes below $3,000 exceeded that for West Virginia (38.3 percent, compared with 32.6 percent).

---

[2] Some responsibility for the approach taken must be attributed to the Harvard study [3] completed in 1962, especially to the orientation toward regional economic objectives. Other contributions to this approach, both conceptual and empirical, are too numerous to mention.

Any methods of estimating contributions of water projects to regional economic development will provide erroneous results if based upon mistaken conceptions of regional economic development and of the role of water project outputs or services in that development. The unbalanced growth doctrine may provide an adequate explanation of economic development of the nation, or of particular regions. However, the specific public and private sector investments contributing to these processes are yet to be determined. Thus, the knowledge base necessary for developing defensible procedures for estimating the contributions of water projects to regional economic development does not exist This absence of knowledge is a major reason professional economists are largely ignored in the process of evaluation, authorization, and construction of water projects. To the agencies that want to construct water projects and to the people who want them, projects are considered economically justified in the absence of definite proof to the contrary.

A Concluding Assessment

After about 30 years of activity to develop and improve methods in benefit-cost analysis, where do we stand? What have we accomplished and what remains to be done? My remarks up to this point emphasize the lack of knowledge of regional development necessary for specifying methods for measuring the more dynamic effects of water projects. Perhaps we should approach the matter differently and ask if we have developed defensible methods for measuring the lesser dynamic effects of water projects. My contention is that we have not.

---

[3] It is not my purpose to develop alternatives to the provisions of the Appalachian Act—however, my approach in such an endeavor would be a direct and major attack upon the human resource problems of the people in the region with a minimum of attention given to developing physical resources.

If we know how to estimate national efficiency gains from water projects, we have not been successful in getting this knowledge established in agency practices. Documents such as the Green Book and the special task force report, as well as agency directives, define primary benefits as net (direct) user benefits of project services. Then these benefits, net of project costs, are purported to represent gains in national efficiency (income). Additional gains in national efficiency are said to be the employment of resources that would be unemployed without the projects. The possibility that primary benefits, as defined, may be inconsistent with the national efficiency objective is not recognized. Agency procedures would count net income to farmland development in the benefit column of the national accounts without an adjustment due to induced interarea or interindustry distributional effects or to the added cost of farm programs. The interarea or interindustry distributional effects would be more severe for products with the most inelastic demands, such as farm products. However, inland navigation displaces some rail and other transportation services, public power displaces some private power, public recreation displaces some private recreation, etc. We need to know what fraction (if any) of primary benefits, as presently defined, should be entered into national efficiency accounts. The portion of primary benefits not entered in the national efficiency accounts would be distributional effects—those project benefits accruing to one area at the expense of one or more other areas, or one economic sector gaining at the expense of another. But there are other income distributional effects of the projects. We need to know the national employment effects and the regional location of these effects, the position of the primary and secondary beneficiaries on the national personal income distribution scale, the position of the losers on this scale, and the division of project effects into those consistent with national social objectives and those contributing only to a regional self-interest objective.

Given this state of our knowledge, efforts to develop procedures relating to "regional dynamics" of water resource development may be premature. A baby should not be expected to run before it has learned to walk.

Estimating the Effects of Water Policies in the West*

HERBERT H. STOEVENER

THE topic of this paper continues to be timely. After decades of analysis of public investment in western water resource development projects, considerable work remains to be done. Public, especially Federal, involvement in natural resource allocation appears to have been increasing during the recent past. Since 1965 Congressional action has concerned itself, for example, with water quality management, additions to the national park system, the protection of estuaries, and the preservation of wild and scenic rivers. The Land and Water Conservation Fund has been established, and state and national planning for outdoor recreational developments has been encouraged.

It will be noted that the above list of actions taken at the national level is not necessarily consistent with the traditional role of the Federal Government in water resource development in the West. This list appears to be biased in favor of the so-called "quality of life" objectives, in contrast to those served by the traditional public investment policy.

Furthermore, as the result of an executive order, the rate to be used for discounting future costs and benefits in Federal water resource development projects has been raised substantially during the recent past. Since much of western water resource development has been of the type requiring high initial capital outlay and producing benefits over a relatively long time span, the general effect of raising the discount rate is to lower the benefit/cost ratio by which projects are evaluated.

Finally, and most recently, the Water Resources Council has published a report [1] suggesting new procedures for the evaluation of development projects. The outstanding features of this report appear to be (1) emphasis on the concept that public investment in natural resources may also serve objectives whose achievement is not readily reflected in the national income accounts, and (2) a set of suggestions for comparing the costs and benefits associated with pursuing these other objectives.[1] It is of interest to this discussion that the report recommends specifically the consideration of a regional development objective.[2]

[1] I am not entirely in agreement with the procedures suggested by the Special Task Force to deal with this problem. However, this issue is not relevant to those discussed here.

[2] Burl Back, in earlier discussion of this session, raised some important questions about "regional development" as a relevant national policy objective.

HERBERT H. STOEVENER *is associate professor of agricultural economics at Oregon State University.*

The above material has been presented to support the argument that future work in the estimation of the effects of water policies on the regional economy of the West will not have to concern itself only with the traditional kinds of public investments made in the area, but will be more and more concerned with the shifted emphasis in national policy. If the above inferences are correct, it may be appropriate to distinguish in our analysis of the effects of water policies in the West among the purposes that these policies are to serve. This proposal is intended to contribute to the usefulness in national and regional decision contexts of the many empirical estimates that will have to be developed in the future. I propose to focus our discussion on three kinds of national policies: (1) those that have regional development as a national objective, (2) those in pursuit of some other national goal, but contributing to economic development as perceived by the region; and (3) those directed at other national aims that are inconsistent with developmental objectives of the region.

Western Regional Development as an Objective

It is difficult to generalize for an area as large and diverse as the semiarid region of the United States. Growth rates differ among states within the region and among areas within the same state. Similar differences exist with respect to idle capacity in the labor force. Presumably, differences also exist among areas in the West in the response of regional income to investments in natural resources. It is conceivable that national natural resource development programs will be employed in the future with the specific objective to enhance economic development of certain areas in the West. For the region as a whole, one might expect that the overall effects of such specific programs would be of secondary importance.

From the standpoint of research priorities, it is important that additional information be developed on the relationship between various kinds of natural resource development programs and their contribution to the development of regions with various economic characteristics. An associated problem is the specification of criteria by which development regions can be delineated.

Regional Development as a By-Product of Other Resource Policies

During the past, water resource development projects in the West have enjoyed vigorous public support in the region. Such support is likely to have arisen from two sources.

First, the primary benefits made available by many projects have generally been underpriced. The public goods nature of many benefits has resulted in making them available at a zero price. Understatement of the capital cost of projects by using too low a discount rate has been one reason for pricing project outputs too low when reimbursement by beneficiaries has been required. The opportunity costs of the water in water resource development projects have seldom been considered. These matters have been discussed elsewhere (see, for example, [2]). It is more important for the purpose of this discussion, to turn to the second source of public support of water development projects in the West.

This source has customarily been referred to as the existence of regional secondary benefits. These benefits accrue because of increased input requirements for the production and marketing of the goods and services produced by the project. They are measured by the increases in payments to primary production factors in the region under consideration. It is generally agreed that these benefits should enter into the national account only under specific circumstances, as they are likely to be offset by negative effects elsewhere in the economy. This, however, makes them no less real from the regional viewpoint. This kind of regional benefit has been an improtant result of traditional water policies in the West.

Studies, too numerous to mention individually, have been conducted in the West to measure the impacts on local economies of selected natural resource development projects. Such studies have concerned themselves with many kinds of projects or programs, and the size of the region studied has ranged from one smaller than a county to large river basins including several or parts of several states. Undoubtedly, the results of this work have generally been useful for the specific purposes for which it was undertaken. However, individually these studies must fail to provide the answers to the broader questions raised by this paper. For example, we have learned very little that would permit us to generalize about regional impacts when there are differences in the types of resource development projects that may be undertaken. Similarly, we are still unable to be definitive about regional effects when the structure of the area's economy is a variable. The relationships between the size of the development project and the size of the geographic area is yet to be determined, as are the relationships between the region in which the development project is located and the rest of the world.

Perhaps it is possible to study systematically the results obtained in work on this subject in order to gain some insights into the broader questions raised here. An alternative strategy would be to study these relationships directly.

The principal published work to take this latter approach is that of Haveman and Krutilla [3], who undertook their study for another reason, namely, to estimate the social costs of water resource development projects during periods of unemployment and idle industrial capacity. Nevertheless, their conclusions shed some light on the topic under discussion here. They concerned themselves with estimating the direct and indirect effects, in terms of industrial and occupational requirements, resulting from the construction phase of twelve types of water resource development projects. Engineering cost estimates were used to derive the on-site requirements for materials and labor. These data were supplemented by the use of the 1958 national input-output model and by a matrix of occupational coefficients by industry, constructed from Bureau of Labor Statistics data, in order to derive the estimate of indirect effects.

The study makes quite clear that, among water resource development projects, stability and diversity exist with respect to their effects upon industrial and occupational groups. For example, durable goods manufacturing generally makes a considerable claim upon project costs. In no case does the percent of total gross output required from this industrial sector fall below 20. Yet the output requirements from this sector per thousand dollars of project costs range from $265 in the construction of revetments to $1,113 for powerhouse construction.

Similar observations can be made about the distribution of the labor demands. For almost all project types, the largest percentage of labor requirements is filled by the "craftsmen, foremen, and kindred workers" group. On the other hand, inputs from this occupational group range from 20 percent of total labor costs for dredging to 44 percent for large multiple purpose projects [3, Table 7]. Furthermore, the effects of these projects are quite different when off-site labor requirements and indirect production effects are taken into account, in contrast to being concerned only with the allocation of project costs to industrial and occupational groups. The above estimates of 20 and 44 percent change to 15 and 61 percent respectively, when the latter basis is used for calculation (computed from [3, Table 6]).

In the context of the discussion of this paper, the estimates of the regional effects derived by Haveman and Krutilla are no less interesting. After analyzing the effects of the twelve types of water resource development projects up on each of ten U.S. regions, they conclude in part [3, page 65] that, with the exception of the Mid-Atlantic and East North Central regions, "the industrial demands placed on the region in which the water resource projects are built are primarily in the categories of trade, transportation, and services." Other industrial demands, primarily for durable goods, favor the Mid-Atlantic and East North Central regions, regardless of the location of the project. Furthermore, there are significant differences among regions in the amount of labor costs retained in the region in which the project is located, given the same type of development project. Similarly, for the same region, different proportions of total project costs are spent locally when the type of project is the variable. For example, for large multiple purpose projects, 52 percent of total project cost is retained locally as labor cost when the project is located in the Kentucky-Tennessee or Mountain regions, compared with 65 percent when situated in the East North Central region. For the West Coast, the numbers range from 44 percent to 55 percent for large earth fill dams and large multiple purpose projects, respectively.

We must hasten to reemphasize that this study concerned itself only with the construction phase of water resource development projects. Consequently, its results should be taken only as an illustration of the types of effects obtainable from such projects. Nevertheless, it appears justifiable to conclude that water policies as analyzed here may be quite discriminating in the manner in which they affect regional growth.

This matter may be irrelevant from the national viewpoint if, as assumed in this section, national policy does not pursue regional growth as an objective. Growth may be an objective of the region, however. I suggest that resource development planning might make allowances for these divergencies between national and regional viewpoints. My general suggestion for implementing this is to include regional interests more than is done currently in the cost sharing for water projects to be developed in the region. I am aware of at least some of the difficulties involved, but I believe that institutional design might be employed productively in this area. The decentralizaton in decision making that would result from regional or local participation in this manner would serve to channel information that currently can reach decision-makers only through political processes. Opportunities would be provided for making national policy objectives consistent with objectives as perceived by the region. Incentives could be provided to locate projects for the production of benefits relevant to the national account in those areas in which their production is most nearly complementary to the achievement of regional objectives. Similarly, a mechanism would be provided whereby project contributions to local objectives would enter into the choice of the types of projects to be undertaken in a region.

Directly related to the above comments is the final subject yet to be treated, namely, the case in which national policies are competitive with regional growth objectives.

Regional Development Competitive with National Resource Policies

As indicated earlier, recent trends in Federal involvement in water resource planning seem to favor the production of those national benefits not necessarily resulting from the traditional kinds of public investments in natural resources. If the latter policies lead to the kinds of regional impacts discussed here, one might speculate that the newer emphasis upon preservation of natural resources in their current state would not have effects that regions perceive to be positive. As a matter of fact, to the extent that developmental opportunities need to be foregone, such policies might make negative contributions to the regional account.

The establishment of the National Wild and Scenic River System is an example. The rivers for which national benefits from perservation are likely to be high are those located in relatively undeveloped regions. Non-development of these rivers may be very competitive with growth objectives of the region.[3] My recommendation for allocating costs between national and regional accounts holds also for this case.

ROLE OF TRANSPORTATION IN AGRICULTURAL MARKETING AND DEVELOPMENT

CHAIRMAN: ROBERT RAUNIKER, UNIVERSITY OF GEORGIA

Transportation and Regional Development in Agriculture

T. E. NICHOLS, JR.

TRANSPORTATION has long been recognized as a strategic factor in economic growth and social change. Readily available, low-cost transportation makes it possible to bring raw materials from the mines, fields, and forests to the factory to be transformed into desired products. Likewise, dependable transportation makes it possible for these factories to supply finished products to their customers where and when they are needed and in the form and quantities desired. Without an efficient, well-managed transport system, the growth and development of an economy and/or region is adversely affected. The purpose of this paper is to discuss in general how transportation and agricultural development are interrelated in both the factor and product markets. By examining the recent innovations in rates and equipment among the various modes of transportation, an effort will be made to explain the interrelationship of these changes with the shifts in regional agricultural production patterns. Attention will also be focused on transportation changes and how they may be expected to alter the efficiency, output, and competitive structure of the agricultural industry in the future.

Importance of Transportation to Agriculture

The location of economic activity is not randomly distributed among certain regions of a country or areas of the world. Rather the location of economic activity is determined by a number of factors, such as regional endowment of resources, production functions for intermediate and final products, transfer cost functions, and demand functions for the final product. The mix of these factors in one area relative to another influences to a large extent both the direction and extent of growth and development in the region.

Because of special characteristics of its products—perishability, seasonality, bulkiness—agriculture is uniquely dependent on a dependable and flexible transportation system. The importance of transportation costs in agriculture is evidenced by the fact that they account for over eight percent

---

T. E. NICHOLS, JR. *is extension associate professor of economics at North Carolina State University.*

of the wholesale value of total farm product shipments.[1] Transportation costs as a percent of wholesale value are much lower in agriculture than for mine and forest products, but they are more than double that for manufactured goods. With agriculture, there is quite a variation in the share of the sales dollar that goes for transportation services—the ratios ranging much higher for perishable than for semiperishable products. Watermelon growers pay nearly 38 cents of each sales dollar for transportation—about half as much as they receive for the product, while the shipping charges for feed grains average about 15 percent of the wholesale price of the products. Increases or decreases in transportation charges consequently have a greater potential impact upon the farmer than in most areas of production.

Changes in transfer costs and services are also of significant importance to processing firms. Individual firms, when evaluating the economy of alternative plant location sites, consider outlays for transportation services incurred in the acquisition of raw materials and distribution of products as costs. The aggregative effect of these individual plant location decisions ultimately determines the spatial structure of an industry.

When businessmen select production sites or seek new locations for their plants, they attempt to select one that will enable them to operate at the most profitable level, typically by minimizing total costs. Even though transportation costs are only one component of these costs, they are an important component of the total cost that is being minimized. Relationships of primary importance exist between outlays for transportation and accessibility to sufficient supplies of raw materials and good markets for products that will enable efficient operation of the plant to be built. Sometimes input or raw material access is dominant in determining the location of an activity and sometimes market access; sometimes neither is dominant, with the result that the location will be at intermediate points.

In general, early stages of processing are material-oriented and later stages are market-oriented while intermediate stages are relatively "footloose" as to transfer considerations. Flexibility in the combination of materials used or products turned out increase the area of locational choice and frequently favor orientation to material sources or markets rather than intermediate points. In any given case, the choice of location will depend on the relative importance of various cost factors as well as noneconomic considerations.

Specialization and Regional Shifts in Agriculture[2]

Over the past several decades, a revolution based on science and technology has altered greatly the structure and performance of U. S. agriculture. Today, American agriculture is characterized by a very high degree of regional specialization.

---

[1] This value represents freight charges in 1959, the last year for which these data were available.

[2] This section draws heavily on [2].

This high degree of specialization is possible only because of the ease of shipment of farm products from one area to another and the ease of receiving in return manufactured products from other regions. With specialization has come increased productivity in agriculture and industry and a higher level of living for consumers in the United States.

Agriculture has not always been organized in this highly specialized fashion. Going back one hundred years or more, we find a much different type of organization in the early stages of expansion of agriculture across the continent.

Prior to 1800, the northeastern section of the United States was an agrarian economy, largely subsistent and self-sufficient in character. The economic system of the South was much different, based largely upon specialized production and export markets. Principal crops consisted of naval stores, cotton, tobacco, rice, and in earlier years, indigo. The West was still undeveloped, with the frontier at the Mississippi River.

The lack of an adequate transportation system within and between regions served as a critical bottleneck to development of commercial agriculture and industry. In the North, the most far-reaching development in transportation was the opening of the Erie Canal in 1825. The canal connected the Great Lakes with the Atlantic seaboard and had a marked effect on agricultural prices and land value, both in the North Central states and in the upland regions of northern New England. Before the canal opened, it required 20 days to transport a ton of freight from Buffalo to New York City overland, at a cost of $100; after the canal was opened, the time was cut to eight days and the cost to $15 a ton.

Water transportation provided a cheap method of moving products, and river and canal transportation reached the peak of its development in this period. In 1830 there were only 23 miles of railroad line in operation; by 1840, this had increased to 2,800 and by 1860 to 31,000. In New York State, canals continued to carry more tonnage than railroads until 1869 when the first transcontinental railroad was completed.

The impact of the development of the railroad upon agricultural and industrial expansion was great. Grain production shifted westward rapidly as families left the rocky, irregular, eroded fields in favor of the more fertile productive land. Livestock followed soon thereafter. The group of industries closely related to agriculture also moved westward, since the processing activities were often weight losing. The Atlantic coast states from New York to Virginia produced in volume 65 percent of the flour in the country in 1840, but only 57 percent in 1850 and 39 percent in 1860 [4, p. 226]. There was a similar shift for meat packing and slaughtering, not only from east to west but also from the Ohio Valley to the Lakes region. Chicago rose to international fame as its pack of pork tripled within the span from 1852 to 1860, while that of beef doubled.

The railroad and waterway expansion of the 1850's opened to many farmers and processors a choice not only for final destination for their product, but various routings to that point. As a consequence, marketing patterns changed radically.

Impact of Transport Changes on Agriculture

The progress of technological changes affecting agriculture involves innumerable and subtle interrelations that are often difficult to trace and document. This stems from the adoption of new inventions and innovations, which is generally slower in agriculture than in industry. However, technological improvements in transportation, for the most part, have been readily adopted by both carriers and users. Because of their rather sharp impact on geographic and commodity relationships, they are more readily identified and measured than are other technical changes, which are evolutionary in nature, occur in small increments, and are significant only in the aggregate.

The primary results of technological change in transportation have been improved equipment, routes, and systems. These changes, in turn, have been effective in bringing revisions in the rate structure, which has traditionally exerted considerable influence on the location and structure of producing areas, processors, and markets.

Effects on Location

When technological change reduces the cost per unit of output of a particular factor, the relative weight of other factors influencing location, such as processing cost differentials, usually increases. Thus, innovations in transport equipment and facilities and changes in freight rate structures exert considerable influence upon the location of industry. For example, refrigeration and the increasing use of trucks for inshipment of livestock have contributed to a deconcentration and decentralization of the meat industry with an increasing degree of specialization by individual firms. The refrigerated rail car provided the first stimulus toward the development of the major slaughter and meat-packing centers of Chicago, Kansas City, Omaha, Sioux City and St. Paul. The existence of rail terminals and major livestock concentration points facilitated their development as major meat-packing centers when first icing and later the refrigerated rail car came into widespread use.

The increasing use of motortrucks and the construction of all weather farm-to-market roads during the 1920's and 1930's led to a major shift in the meat marketing industry. It lessened the reliance upon converging rail lines for the inshipment of livestock at the traditional terminal markets. In addition, mechanical refrigeration on both rail cars and trucks contributed to a greater intermodal competition in the transport of fresh meat. Slowly a new economic pattern evolved. Packing plants moved increasingly into the producing areas nearer to their sources of supply. Small independent and specialized slaughter plants taking advantage of the unique markets offered by the retail chains gained an increasing share of the market. Between 1947 and 1963, the share of the total meat packaging industry accounted for by the four largest firms declined from 41 percent to 31 percent [7]. Further deconcentration, however, may be slowed due to economies of size in processing and distribution. Rapid technological advances in aircraft design and centralized packing promise to stimulate revolutionary changes in traditional concepts of physical distribution. It appears that cutting meat to individual specifications and air freighting it to central markets will be economically feasible within the next 15 to 20 years.

Over the last two decades, it has become clear that distance is no longer a limiting factor in the development of specialized meat production. Improved transportation through a vast interstate network of superhighways has hastened feedlot relocation out of the Corn Belt to the Southern Plains, stretching from West Texas to Nebraska. There is ample evidence that the trend toward further relocation of feedlots and packing plants will continue.

Dramatic shifts have also occurred in the location of processing plants for grain and grain products as a result of the introduction of "cost-oriented" rates in the early 1960's. For many years, flour mills were located at intermediate or transshipment points between wheat producing regions and flour markets [11]. The transshipment orientation was supported by a structure of transportation rates based on a value of service criterion. Utilizing intransit milling privileges, alternate milling centers could experience the same total transportation costs; however, loading and unloading costs could be eliminated if processing took place at points of transshipment. Thus, flour mills tended to locate along major railroads near their sources of wheat supply.

Elimination of the transit privilege and the rate reduction given by the railroad on wheat and other coarse grains, without similar reduction on flour or other processed commodities, has provided economic incentives for mills and other grain processors to relocate nearer the major consuming areas. The relocation of flour, feed, and soybean mills as a result of freight rate adjustments and expanded markets has been widespread throughout the eastern and southern states in recent years. As long as consuming areas are separate from producing areas and transportation rates for products are higher than those for raw materials, further reorientation of processing plants to consuming centers will likely occur.

Effect on Firms

Equipment and rate innovations can and do alter scale relationships of firms that affect their efficiency, output, and competitiveness. The changes in transportation costs for feed ingredients have usually been stressed in any economic analysis of the price of poultry feeds in the South versus the Midwest. Bluestone [1, p. 32] attributed the relative decline in the cost of poultry rations in the South over the previous 15 years to the navigational improvements in the inland waterways that tie the Southeast to the surplus corn producing areas of the Midwest.

Kriesel [5] described the decline in costs of feed delivered to poultry producers in the Southeast as initially arising from introduction of water transport of grain on the Tennessee River, accompanied and later superseded by the growing role of motortruck transport and, most recently, by introduction of a new rail freight service that slightly undercut the truck rates.

In an economic analysis of changes in the structure and location of the market egg industry, Morrison [6] found that lower feed prices due to freight rate differences between regions contributed to the Southeast's competitive advantage in eggs as well as in broilers.

Thus, it appears that relatively lower freight rates on feed, which represent approximately 60 percent of the cost of producing broilers and eggs, has been an important factor in the rapid expansion of poultry in the Southeast.

Multiple-car rates and especially train rates favor large scale operations both at points of origin and destination. These innovations in rate making, if widely adopted by the railroads, could have a significant influence on the size and number of firms in the industry. Advantages accruing to the grain processing industry will be available only to those firms that have sufficient unloading and storage capacity to make consistent use of high capacity hopper cars on a train load or multiple-car basis. Obviously, small elevators at points of origin and small feed mills at destination are at a disadvantage in the movement of grain in large lots.

There is also evidence of savings in per unit transportation costs. Felton indicates that out-of-pocket costs for shipping grain in a standard boxcar are about 8.50 mills per ton mile [3]. Experience of the Southern Railroad, shipping coarse grains from Cincinnati, Ohio, to Raleigh, North Carolina, in five-hopper car units, indicates costs of about 5.73 mills per ton mile. Shipments of 100-hopper cars from central Illinois to New Orleans can be performed at about 1.50 mills per ton mile. Thus, there appear to be significant opportunities for reduction in the cost of transportation of grain whenever the volume of grain between origin and destination is of sufficient magnitude to justify continuous shuttling of a unit train between these points.

While some shippers of agricultural products have realized substantial savings on transportation charges, benefits from intermodal competition appear to have been limited to some extent for others.

Impact of Competitive Pricing

The selective implementation of high volume, nontransit rates can make an intermediate location less profitable for milling and storage, but can also leave other regions disadvantaged because they do not automatically receive the same low rates.

Seaver has observed that ". . . in face of severe competition from the Southeast, it is doubtful that the Maine and Delmarva broiler producing areas can survive over the next ten years. Their ability to do so will depend to a great extent upon feed freight rate relationships between the Northeast and Southeast and upon the likelihood of the Southeast finding some profitable alternative farm enterprise other than broilers and eggs . . ." [8].

Concern has also been expressed both about the changes in pricing of transportation and the adequacy of service [10]. Proponents of traditional rate relationships argue that, if branch lines have inadequate capacity to handle the "Big John" cars or other equipment, they may be expected eventually to discontinue operation, with a resultant financial loss or burden to these newly created "out of position" firms. As specialized equipment and fewer multiple purpose cars become more prevalent, the ability of the carrier to move seasonally produced and highly perishable items may also become more restrictive. Ownership by the volume shipper of a substantial portion of the limited supply of cars could adversely affect both the small shippers and receivers.

The impact of changing prices, services, policies, and rate structure upon market structure and the competitive position of agriculture in the various regions is and should be a major concern to everyone. One can build a strong argument that a pricing policy that maximizes net firm income does not necessarily result in the optimal allocation of resources in other industries; or it may not necessarily represent a maximum net social gain. To those firms and industries that are disadvantaged by the greater rate making freedom on the part of carriers, this concentrated impact on their own competitive position has been far more immediate and apparent than the savings in transportation costs that are being brought about by improved technology and increased competition. Disruptions of established production, processing, and distribution patterns have significant short-run costs for economy, adversely affecting the value of existing facilities and perhaps in extreme cases even forcing their abandonment [9].

But attempts to preserve rate structure and services established to fit conditions that no longer exist also impose important long-run costs on the economy as a whole. The offsetting losses to some firms, communities, and regions should be set against the gains to other groups from competitive rate adjustments and the transition to competitive pricing.

Cost of production and distribution must be considered together. Economic efficiency is concerned with the total allocation of all resources, and the location of producing, processing, and marketing facilities is one element, albeit a very significant one, in determining total economic cost. In the past, resource cost differentials have been concealed to a great extent by use of group rates for shippers. Production and marketing areas became more extensive and more expensive in terms of resource utilization than would have been warranted had rates for moving the same product reflected the true costs of providing the service. The fact that costs were equalized to provide producers access to several alternative markets obscured the higher total cost of uneconomically located production and processing facilities.

Competitive pricing for farm product transportation services tends to force rival carriers to supply each shipper with service at its cost to them. When competition is present, it also tends to allocate traffic to the modes of transportation able to haul most efficiently. Over the longer run, the geographic differentials that are reestablished by competitive pricing foster locational patterns that minimize total economic costs, including the cost of transportation. Where long standing geographic patterns are uneconomic, this process cannot be carried out without transitional readjustments which might inflict hardships on individuals and some economic cost to society as a whole.

Summary

Transportation, as one of the factors of production in our economic process, has played a dominant role in the structural evolution of U. S. agriculture. Likewise, the development of transport facilities has made an important contribution to our nation's welfare and to our individual standard of living. With transport facilities of early America, it was generally uneconomical to move commodities of low value per unit of weight for long distances, and the inhabitants of each region had to become relatively self-sufficient. Long-distance trade, even if possible, was not practical—particularly for bulky commodities. Today, vastly superior transportation equipment has greatly reduced the cost of moving people and goods, facilitating the production of goods and services in locations with lowest production costs. From an economic standpoint, there have been four major revolutionary innovations in transport technology since the 1820's. Each innovation has played a significant part in the regional development of agriculture by making some locations economically obsolete but opening up investment opportunities in new areas. The first two were the canals and railroads, whose effect was toward the concentration and centralization of production, processing, and marketing. Later came the motor truck and the airplane, which set in motion decentralization and deconcentraiton tendencies, particularly in the production and processing of livestock.

Although dramatic changes in transportation have taken place, technological advances in transportation are certain to continue. These changes will affect both agricultural and nonagricultural industries. To the extent that agricultural firms adjust to take advantage of changes in transportation, greater regional specialization will occur. This regional specialization is consistent with agricultural development and, indeed, with total economic development.

Economic Considerations in Rate Making and Rate Structures for Farm Products

JAMES H. LAUTH

THE goods that farmers grow and sell must be transported and delivered in the form and at the time and to the places that consumers desire. But the transportation of farm products does more than create the place utility that gives them real value. Without transportation we would have to spend most of our time raising food—and the food would be limited to the kinds that grow in the climate and soil of our neighborhoods.

Our highly developed transportation system eliminates the need to produce the bulk of our food close to our population centers and permits a high degree of regional specialization of farm production. Our grain, cotton, citrus fruits, and many other crops are produced in those areas best suited for their production by soil, climate, and topography and to which scientific farming and modern farm machinery can be applied. The result has been to make possible tremendous economies in production and drastic reduction in the cost of food purchased by U. S. consumers.

The charges assessed for the movement of farm products, in terms of both the level of freight rates and the inter-commodity and inter-regional rate relationships, are vital to this regional specialization as well as to efficient utilization of resources so that the widest possible markets, domestic and foreign, can be attained at the lowest possible cost.

In this context, this paper will discuss the economic considerations used in the makeup of rate structures for the movement of farm products. It will deal mostly with the railroad transportation of unmanufactured (or unprocessed) farm products.

Basically, railroad rate making has given consideration to two pricing principles: (1) cost of Service, and (2) value of Service.

Cost of Service

Increasing competition from trucks and barges has firmly established the cost of providing rail service as an important factor in pricing rail services. For particular shipments, the level of railroad costs is influenced by: (1) quantity shipped, (2) distance, and (3) operating conditions. These factors have been adequately discussed in numerous publications and there is no need to repeat here.[1]

---

[1] See, for example, [1, pp. 271–278].

JAMES H. LAUTH *is chief of the transportation services branch of the Consumer and Marketing Service, USDA.*

Railroad rate making must give consideration to the nature of railroad costs in pricing services, particularly in establishing the floor under which rates should not be offered. Rail costs are characterized by a huge "sunk" investment, a high proportion of fixed costs, and the existence of excess or underutilized capacity [4, p. 36–44]. The heavy fixed expenses in railroad plant cannot be adjusted with changes in traffic volume.[2]

These costs have to be met whether traffic moves or not. This makeup of railroad costs allows the use of incremental (out-of-pocket) costs in pricing rail services on particular segments of traffic. All rates do not have to contribute a proportionate share of overhead costs. The railroads are often better off with additional traffic than without it, even though the rate needed to attract the traffic contributes less than its proportionate share to overhead costs. That is, rates can be established at a level that provides only a small margin above the direct costs occasioned by the movement of an additional volume of traffic from A to B. The additional revenue from such traffic contributes to the overhead burden; improves railway net income; and, by spreading the burden of fixed costs over a greater amount of traffic, tends to hold down rates paid by shippers of other traffic in noncompetitive areas.

Interstate Commerce Commission "Rail Form A" out-of-pocket costs, developed for regulatory purposes, provides regional unit costs which, over the long-run and with average density of traffic, have been found to be variable with traffic changes. These costs include 80 percent of freight operating expenses, rents, and taxes (excluding Federal income taxes), plus a return of 4 percent after Federal income taxes on 50 percent of the road property and 100 percent of the freight equipment. They reflect the relative amount of transportation received by "average" regional shipments, and in so doing provide a measure of the differences in the unit costs for shipments of varying sizes in different types of equipment and for varying lengths of haul which, in turn, can justify differences in the rates charged.

The function of "cost-of-service" in rate-making, then, is to identify the minimum (out-of-pocket) costs so as to set the "floor" for railroad pricing and to provide a plane to which demand factors can be related. Rates are then established at various margins above that floor at levels that are responsive to demand factors (value-of-service) and that reflect such cost factors as quantity shipped, distance, and operating conditions.

---

[2] Trucks and barges not only have lower investment costs but also substantially higher variable costs and and therefore can adjust more readily to changes in traffic volume. Rail variable costs are estimated to be about two-thirds of total costs, while for truckers they rise to as much as 90 percent, and for barge operators they account for perhaps 95 percent [4, p. 37–38].

Value of Service

Locklin defines value of service as the highest charge that can be levied without preventing a shipment from moving [3, p. 144]. He explains: "That limit is determined by no one factor. Sometimes the effect of the rate on the demand for the article sets the limit; sometimes the limit is the difference in prices in two places; sometimes it is the difference in cost of production; sometimes it is the difference in cost of production if the opportunity cost at point of destination is also included; and sometimes the limit is set by the cost of obtaining the commodity from an alternative source of supply. But whatever may determine the limit of the charge, the limit is real and cannot be ignored. It says to the railway manager who is making rates: Thus far shalt thou go and no farther." This factor, then, is the demand factor in the pricing of transportation, whereas the cost of service factor has been referred to as the supply factor [2].

One element of value of service pricing gives consideration to commodity value and tends to justify higher rates on a high-priced commodity than on a low-priced commodity where the two have similar transportation characteristics. A rate of $2.00 per hundredweight might well reduce demand (and therefore the movement) for wheat worth $2.00 per hundred weight at origin, whereas the same rate would hardly affect the demand (or movement) of a 100-pound television set worth $300.00 at origin.

The two more important elements of value of service pricing are market and product competition and intermodal competition (and intramodal competition, to a lesser extent).

Market competition as a pricing factor takes into consideration the economic and commercial conditions surrounding the production and sale of a particular commodity. Market competition plays its part in rate determination when new markets are desired to be developed for a particular region's production. The consideration that led to the Northern Line's reductions in westbound rates on spring wheat in 1965 was not competition from other modes of transport but rather competition from Canada in the selling of wheat in the Asiatic market. And the "inverse nature" (a higher rate for the shorter than the longer distances) was dictated, certainly not by cost considerations, but by the nature of the commodity pricing and marketing system. In the recent railroad proposal to reduce export rates on winter wheat from Texas, Oklahoma, and Kansas to California ports, the prime consideration is whether or not reduced transport costs (charges) will create new business to make U. S. wheat price competitive in the Asiatic market with other wheats, principally from Australia and Argentina. A further market consideration will be the potential loss of flour tonnage if a lower export wheat rate adversely affects the marketing capability of flour mills, at origin or destination, to sell in the West Coast markets. Although truck competition was significant, the key to the reduction in feed grain rates to the poultry industry in east Texas was the recognition that a lower delivered cost of feed would not only keep a market for feed from the Midwest but would help that market to grow and produce more poultry, use more feed and help the economy of the area develop and grow and use more goods and services.

Market competition also comes into the pricing formula when two or more producers of like or substitutable products compete for sales in the same markets. The western railroads have long maintained lower rates, distance considered, on fresh fruits and vegetables from western origins than the rates from less distant producing areas in Florida. Such rate-making serves the western railroads by achieving more competitive pricing of California oranges, for example, with Florida oranges, allowing production to be marketed in the distant eastern consuming markets.[3]

Probably the most important single element in demand (value of service) pricing is the presence or absence of intermodal competition. When the basic rate structures for most farm products were established in the early 1930's, intermodal competition was relatively insignificant. The rate structures thus established were primarily market oriented with little consideration given to the relationship to the cost of providing the service. Emphasis was placed upon development of a rate structure that would provide freedom of movement for the products of agriculture so that as many producers and processors as possible could reach as many markets as possible. Factors such as definite relationships between the rates on raw material and the products manufactured therefrom, equal treatment of large and small shippers, recognition of competitive relationships between producing areas and marketing areas by the inclusion of transit privileges in the rate, blanket rates, group rates, and proportional rates all characterized the rate structures thus established.

Following establishment of these basic rate structures, the railroads in the 1930's, 1940's, and 1950's increased the rate levels generally on an equal basis thereby maintaining the existing rate structure and competitive rate relationships.

However, since about 1958, by which time the railroads' share of transportation of total intercity freight movements had fallen to about 43 percent of the total, the railroads have started a drive to reduce rates in areas where they face competition from trucks and barges. These selective reductions, achieved through lowered unit cost of operation and to meet intermodal competition where it exists, have had far-reaching effects on the competitive relationships between producing areas and processors and the marketing system.

---

[3] Truck competition is not a factor here, as over 90 percent of fruits and vegetables arriving in eastern markets from western origins are by rail.

Rate reductions given by the railroads in one area but not in a competing area because of lack of intermodal competition can cause loss of former markets if not offset by other economic advantages. Lower rates on raw products, which in many instances are less costly to transport than processed commodities, can—and do—cause relocation of processing plants to the major consumption areas. Unit-train rates and multiple-car rates offer vastly lower rates for the large-volume shipper, and thus can have a significant influence on the size and number of firms in an industry. Mileage rates, such as those now established on corn in the east, favor those located close to their markets. The old rate structure protected hundreds of small geographically scattered processors and handlers by equalizing rates within large origin and destination groups. Elimination of transit privileges creates advantages to those marketing or processing facilities located in the origin or destination areas and disadvantages to those at intermediate location [1, pp. 279-281].

The recent nationwide increases (ex parte 256 and 259) have been selective in nature by the establishment of lower increases on commodities in areas where there is intensive intermodal competition and higher increases in non-competitive areas, thus further widening the relationships between producing areas.

Although intermodal competition has increased considerably over the past few years, there are significant areas where railroads presently provide the only effective transportation service. Key factors of distance, volume, and nature of the commodity seem to be significant in minimizing the effectiveness of motor carriers as competitors in many instances. Motor carrier competition diminishes with increases in distance, e.g., fruits and vegetables from California to New York. Volume shipments, both in terms of amount per car and annual volume, tend to be captive to railroads, e.g., covered hopper car shipments and unit train shipments of grain and unit train shipments of coal and ore. Low value commodities move almost entirely by rail or barge. With respect to exempt commodities, many truck movements are curtailed by lack of commodities to haul into the producing area. The cost of motor carrier service in these instances would be simply too high, whether private or for hire, to permit movement. Barge carriers provide very effective competition to the railroads on volume, long distance, and low-rated commodities. Barge lines, though, are handicapped by their geographic limitations and restricted by frozen waterways in the winter and, in the case of some waterway systems, by low channel depth and lock limitations.

Some captive rail service examples are fruits and vegetables from the

West Coast to markets east of the Mississippi River; potatoes from the west (Idaho, North Dakota) to eastern markets; potatoes from Maine; wheat from Montana and part of North Dakota and South Dakota; wheat from Idaho; barley from North Dakota; grain to New England; grain to New York, Pennsylvania, New Jersey and Delmarva; cotton from California, Arizona and Texas to Carolina mills; and westbound transcontinental export grain.

Summary

Rail rates are not determined by a proportionate allocation of total costs to each shipment. In the aggregate, of course, total costs must be met; but total costs need not be recovered for each shipment because of the inherent nature of railroad costs—a huge "sunk" investment, a high proportion of fixed costs, and excess capacity in the railroad plant. Incremental cost pricing is economically sound under such conditions and is used to gain (or hold) traffic that otherwise would be lost to competing modes or would otherwise be unavailable for movement because of market or product competition.

The resulting rate structures are comprised of rates that vary, both within a particular commodity rate structure and among the various commodity rate structures, from levels that provide a small margin of revenue above out-of-pocket costs to those that provide revenue considerably over fully distributed costs. For example, in 1966 the commodity group "Nonmetallic Ores" returned a ratio of revenue to out-of-pocket costs of 101 percent and a ratio of revenue to fully distributed costs of 69 percent. The commodity group "Ordnance and Accessories" returned a ratio of revenue to out-of-pocket cost of 365 percent and a ratio of revenue to fully distributed costs of 277 percent. Farm products, for the same year, yielded a ratio of revenue to out-of-pocket costs of 124 percent and ratio of revenue to fully distributed costs of 93 percent.[4]

The determining factor that influences the level of particular rates above the "floor" is the railroads' response to demand. Demand comes principally from truck and barge competition and market and product competition. There have been a number of significant downward adjustments on farm products in recent years that were established as a result of intermodal competition. These reductions were achieved through lowered costs by operation by establishment of incentive loading rates, volume rates, and "bare bones" rates, which reflect more of a relationship to cost of providing service than the historic "value of service" rate structure. However, there are many areas of the country where sufficient truck or barge competition for farm products does not exist. In these areas, recognition of market competition is becoming more evident in railroad pricing of farm products. Because farm products are relatively low in value and are grown in areas best suited by soil, climate, and topography, rates must not be so high as to prohibit or restrict movement to national markets. Unlike manufacturing plants, the location of farming is fixed by nature and cannot, and should not, be restricted by the absence of truck or barge competition.

Last year Montana was third among states in the production of wheat, which accounts for about seven percent of the total U. S. production. Montana also ranks third in barley production. These two grains are the major agricultural crops in the state.

Montana's calf crop totaled 1.4 million head last year. By coincidence, we shipped nearly 1.4 million head of cattle out of state. Some simple arithmetic illustrates the magnitude of the volume of livestock and grain as related to transportation and mode of transport. The latest information indicates that 65 percent of Montana's out-of-state cattle shipments are made by truck. An average shipment is moved slightly over 700 miles and contains 50 head per truck load [1]. This means that over 18,000 truck loads of cattle destined for out-of-state markets were made last year. Another 600,000 head are shipped by rail for an average distance of 718 miles.

Montana had a 124 million bushel wheat crop in 1968. Over 100 million bushels must eventually find their way to out-of-state markets. Although much is in storage at the present time, a 100 million bushel crop would fill 30,300 hopper cars holding 3,300 bushels each, or 606 trainloads of 50-hopper cars each. On the other hand, it would require 87 thousand super trucks (1,150 bushel units) to haul the same quantity. In recent years our barley crop has averaged 48 million bushels, which is equivalent to 14,500 hopper carloads, or 41 thousand truck loads of 1,150 bushels each.

Montana has major grain markets to the east and west. At some points in Montana, grain rates are the same whether shipment is to be made to eastern or western markets. Our primary terminals are Portland and Seattle to the west and either Minneapolis or Duluth-Superior to the east. Either one of these terminal markets may be from 700 to 1,100 miles from our producers, depending upon the origin of shipment within the state.

Pricing Transportation Service

Farm products, more than manufactured goods, depend upon transportation for the creation or preservation of their value. Place utility—the value added to farm products by moving them from where they are abundant relative to demand to where they are less so—constitutes a high share of their final price [5].

The average cost of transportation for grain in Montana is slightly over 30 per cent of the terminal market price. Consequently, any percentage increase or decrease in transportation charges has a much greater impact upon our agricultural producers than in many other areas where transportation charges are a much smaller percentage of the terminal price.

Ulrey [5] says, "Important though it is, the high ratio between transportation charges and final market values is not the most significant aspect of agriculture's dependence on transportation services." He adds, "Agriculture's demands upon transportation are seasonal, variable, and so unpredictable that they require a high degree of flexibility on the part of the carriers. Producers can control these uncertainties only to a very limited extent." However, wheat producers in Montana can exercise some control over the seasonality of marketing because there is enough farm storage in the state to hold slightly more than two years' production of wheat. Even with this alternative of farm storage, there is some seasonal pressure on carriers.

Importance of Transportation Service to Montana

Ulrey also says, "The emergence of strong and effective competition for any specific traffic movement depends on two conditions. First, the traffic must be sufficiently attractive to provide carriers with incentives to compete. Second, the relative advantages and disadvantages (including costs) of the service offered by competing carriers must provide shippers with effective alternatives. The *intermodal competition* that has already emerged from much agricultural traffic and is extending around a widening geographic periphery shows that alternative carrier types have both incentive and the ability to compete" [5, p. 4].

Intermodal competition, as described by Ulrey, has not been apparent to shippers of agricultural commodities in Montana. Its lack has led to frustrations of producers and merchandisers. Producers and shippers have felt that the traditional economic advantage of competitive pricing is not working toward their benefit in Montana. Advantage of intermodal competition lies in the pressure it brings on the carriers to underbid rivals for each haul. In only a few locations do rail carriers effectively compete with each other for grain in Montana.

The following reasons provided by agricultural producers in Montana were the basis of their frustrations in the mid-1960's.

1. *A discrepancy of rail grain rates within the state of Montana.* Wheat shipped from Havre, Montana, to west coast destinations was moving for 25 cents per hundred more for export than wheat from Bozeman, Montana, to west coast destinations when the distance was nearly the same [Table 1]. They were also upset because from Denver, Colorado, the freight rate to the Pacific North Coast was only 70 cents per hundred, while at Havre, Montana, it was 76 cents per hundred for export [3]. Harve is roughly only about two-thirds as far from the Pacific North Coast as Denver.

2. Producers were suffering from a lack of information on where their grain was going from Montana.

3. They were questioning the pricing of grain in the country on the basis of the Minneapolis price less freight.

4. They felt that there seemingly was no benefit to them from the cur-

rent equipment technology by rail carriers and trucking firms.

5. It was not apparent that they were receiving any benefit from some of the innovating rate making that was going on in other states that were producing and shipping grain.

6. The intent of the inverse freight rate for export was not well understood by a majority, and they felt their freight pricing was based more upon what "the traffic will bear" than in many other states.

It was into this framework of concern, frustration, and, in some cases outright anger on the part of some agricultural producers in the state that the Division of Agriculture at Montana State University launched a joint research and extension transportation project in the spring of 1967.

Challenge to Research and Extension

The basic challenge of this project was to determine what the real transportation problems were and what alternatives there were for adjustment in those areas that are deemed necessary after investigation.

Montana approach

Community meetings were held with agricultural producers and the grain trade. An advisory committee meeting was held that involved staff from the College of Agriculture, College of Engineering, Montana Crop and Livestock Reporting Service, Cooperative Extension Service, Railroad and Public Service Commission, Federal Extension Service, and the Upper Great Plains Transportation Institute.

It was determined that the major research emphasis should begin with the wheat transport problem. It should start by developing basic data and an inventory of the existing situation, since no one had adequate data upon which to base many of the arguments that were causing a great deal of concern.

The first step involved working with the grain trade to obtain grain shipment data in Montana. After working with the regional offices of the major companies and country elevator organizations, a mail questionnaire was approved. Data for fiscal year 1966-67 was obtained, and this was published in January, 1969; data for 1967-68 and 1968-69 will be published by the end of this year. Building on the experience and information obtained, a system has been worked out whereby shipment data will be obtained on a regular basis with the cooperation of the grain trade.

Seventy-seven percent of all grain shipped from Montana was by rail. Backhaul trucks handled another 14 percent and one-way trucks handled 9 percent. Indeed, railroads in Montana are the number one carrier of grain.

In 1966-67 rails hauled 83 million bushels of grain; 86 percent of it moved west and the remainder moved east. Of the 24 million bushels shipped by truck, 17 million bushels went to out-of-state markets—Minnesota, Washington, and California were the most important destinations. This data on destinations was the first that many producers had had on where their grain was being shipped.

This dominant role of railroads in the transport of Montana grain left some grain producers with a feeling of helplessness. If the value of the transport service is high to the user, the price can and will be high because the user has virtually no alternative method of shipping. The automatic question raised was: Without the competitive factor of intermodal competition, how is it possible to bring about any adjustments in transportation price that would be more palatable to the shipper of grain?

If the rail carriers are pricing their service from a demand orientation, and there is no effective competition, are they then charging what the traffic will bear? Consultations were held with the Montana Wheat Research and Marketing Committee, grain growers, grain trade groups, and with the rail carriers in an effort to determine what might be some of the alternativies in the Montana grain transportation situation. Obviously, the rail carrier of grain in Montana is not subject to a great deal of competitive pressure. Without the competitive factor, how can adjustments be made in transportation pricing?

Attention focused on four factors that would result in grain rate adjustments by rail carriers:

1. Increased tonnages resulting from lower rates.
2. Increased equipment utilization.
3. Reduction of accessorial services.
4. Blanket rate making.

The data indicated very little opportunity to increase tonnages with reduced rates for the state; the exception was the Northeast Crop Reporting District where 28 percent of the grain shipped from elevators was by truck.

Rail carriers admit to a very low equipment utilization. In merchandising of grain, considerable additional services are furnished by rail carriers that are not furnished by other modes.

The accessorial services of generous loading and unloading times, transit, diversion, and inspection stops are time consuming and are provided by rail carriers from Montana. Testimony in I & S Docket 8417 indicated a reduction of accessorial services could reduce turn-around from 19 days to 12 days from Wilbur, Washington, to Pacific Northwest ports. Such a savings in time has the same effect as increasing the rail carrier's car fleet. Thus, rail costs are reduced and part of the savings could benefit producers, although there is no guarantee that any of the savings will be received by the shippers. However, a study conducted on the Southern "Big John" case indicated that the entire reduction was transferred to the producer [2, p. 5–6].

After discussions by all interested parties, it appeared that the best opportunity for the isolated interior locations of Montana would be to concentrate upon eliminating some of the extra additional services provided by rail carriers that would help them to increase equipment utilization. As a result of this approach the Northern Lines Committee docketed a "no-frill" seasonal rate on grain from Eastern Montana points to Minneapolis-St. Paul and Duluth-Superior, subject to the following conditions:

1. No inspection, sampling, or hold privileges will be permitted under railroad tariff rules at origin, intermediate points, or at destination.
2. Forty-eight hours free time for loading and 48 hours free time for unloading. Petition to be filed with the Interstate Commerce Commission for relief in connection with these rates from order requiring seven days free time at Head-of-the-Lakes.
3. Specific place of delivery must be designated at time of billing. No orders for diversion or reconsignment will be accepted. No orders will be accepted to hold cars short of billed destination[4]

Another alternative explored was the use of multiple car shipments with minimum tonnages. As yet, discussions of this in Montana have not reached any agreement. During 1968 there were shipments of wheat in Montana on a trial trainload basis. A 50-hopper car trainload was shipped on the Great Northern Railroad from Wolf Point, Montana, to Portland, Oregon, and a 40-hopper car trainload was shipped on the Milwaukee Railroad from Great Falls to Pacific Coast ports.

The present proposed "no-frill" rate going east with the seasonal aspect is more encouraging. The seasonal rate was added for two reasons: (1) It is an attempt on the part of the carrier to level out seasonal movements, and (2) it is following the pricing practice of service based on demand.

Traditionally, there has been a much stronger demand for rail cars all along the system during the harvest season, which generally runs from July 1 to approximately November 30. As a result, the carrier is unable to furnish all the cars needed to fulfill the demand, and the price of service is higher than in the remainder of the year. The "no-frill" rate has not yet been initiated, and we have no way of knowing whether it will fulfill these two requirements.

If the "no-frill" seasonal rate is initiated, producers who have farm storage may want to store their grain during the season of high rates and attempt to move it to market during the season of lower rates—as much as five cents a hundred lower. Grain elevators may buy during the harvest season and fill their house at prices reflecting higher rates, then hold until the lower seasonal rate is implemented. To what extent these practices might be adopted will not be known until the proposal has been initiated and used by the shippers.

Role of agricultural economist

At this point, one might say that the agricultural economist who is working on a transportation problem, but has little or no formal training or background in transportation, will have only limited success in helping to ease the frustrations of shippers in an interior location. Any economist who is entering work in transportation would be well advised to consult early with management of different modes of transportation and with management of marketing firms and shippers to determine what the needs are and what approaches should be taken. Information needed for management decisions and the best method of approach to obtain this information can be determined through these consultations. It would seem that university extension and research economists can proceed to obtain relevant data by involving the people who are directly concerned. Keep them informed as progress is made in collecting data so that management decisions can be made as soon after publication as possible.

If we would have to isolate any one thing learned from this experience, it would be the very definite need for active involvement of all people who are interested. Keeping them constantly informed of progress is important to the success of such an effort. If the economist is going to fulfill the need and the demand for his services, he will want to perform the function of a coordinator as well as researcher. Adaptation of economics to the transport situation will help to provide information needed for decision making. Our efforts could be termed a *service*; if so, we are pleased that we have provided it to Montana.

During the last 18 months we have worked closely with the Montana Wheat Research and Marketing Committee. They have made a significant financial contribution, as well as assisting in the coordination and development stages of the project. Without their help and contribution, many doors that have opened grudingly would likely still remain closed.

We would urge economists to become involved in transportation problems. It is exciting, frustrating at times; but most of all, it provides some satisfaction that comes from being a part of the action.

Discussion: Role of Transportation in Agricultural Marketing and Development*

JOHN O. GERALD

The papers presented today all seem to have a common theme: The actions of railroads in rate making are upsetting equilibriums under which agriculture has functioned for many years. Commodity production areas, inter-commodity relationships, locations of processing and storage facilities, sizes of firms—all of these elements are undergoing change, in part at least, as a consequence of crumbling rate structures.

In discussing changes in rail rate structures now under way and means for preventing them from adversely affecting agriculture, it is important to remember that we have no national railway system. Rather, we have some 70 or so Class I railroad systems and many other smaller systems. Traffic patterns in this country are such that most of the rail-truck-barge competition affects some of these independent rail systems to a much greater degree than other systems. Some of them will recover fixed costs into the forseeable future, but others cannot do so at present. If sunk costs of the railroads must be covered whether or not traffic moves, as Lauth and some transportation economists claim, we may soon have considerably fewer rail systems and miles of track. However, whether or not we have fewer miles of track really should depend upon the revenue earning potential of the track in relation to the revenue earning potential of the right-of-way in some alternative endeavor. Sunk costs are sunk. It is my belief that recognition of this economic truism by railroad management accounts for many of the actions we have observed in recent years.

Lauth discusses cost of service and value of service pricing principles. The cost of service principle is relatively straightforward. If competition from exempt trucks has reduced the traffic of unmanufactured agricultural commodities available to railroads, the Interstate Commerce Com-

JOHN O. GERALD *is an agricultural economist with the Economic Research Service, USDA.*

mission may allow rates that cover only out-of-pocket costs of the railroads to become effective. Otherwise, rates below fully-distributed costs may not be authorized. If out-of-pocket costs are good approximations of marginal costs of the railroads, efficient resource allocations are encouraged by this permissiveness of ICC.

Lauth's description of the value of service pricing principle should leave little doubt in your mind that substitution of the phrase "monopoly pricing" does little or no injustice to the description of the principle. ICC has exercised some control of the extremes which otherwise could occur under monopoly pricing by the railroads. Nonetheless, knowledge that value of service rate structures existed throughout the period of a near technological monopoly by railroads, roughly 1860-1950, provides an understanding as to why rate structures are now crumbling.

Lauth ends with the conclusion that "the location of farming is fixed by nature and cannot, and should not, be restricted by the absence of truck or barge competition." He fails to hypothesize that internal subsidizations by our railroad industry helped nature in fixing present locations of agriculture and to give us the prescription by which location is to be maintained.

Agricultural rail rate structures, as noted by Lauth and Nicholls, held stable for decades, despite conflicts of interest among subsets of the railroad using public, among subsets of the railroad owning public, and between these two publics. As long as railroads had a near technological monopoly, legal external rate structures could be maintained. Flows of funds internal to the railroad industry through divisions of joint rates, per diem rentals, etc., permitted some balancing of the equities of specific subsets of the railroad owning public, with no change in external rate structure goals. Even so, the long-term stability of external rate structures is quite amazing in many respects.

In my opinion, internal flows of funds between our many independently owned railroad systems will continue to be very carefully scrutinized by railroad managers. These managers owe a responsibility to their investors to recover sunk costs. The level of aggregate railroad earnings is such at present that permitting new flows to arise, and even letting traditional flows to continue unchallenged by management, is criminal behavior from the viewpoint of investors. If Lauth has internal subsidization in mind as his prescription for maintaining the location of farming, he also must have in mind complete regulation of transportation, including private carriage, or alternatively, public guarantees to railroad and regulated truck owners that their investments will be covered. I have found no estimates of benefits and costs of either of these possibilities in relation to the benefits and costs of agricultural relocation to optimize use of transport services.

Nicholls discusses the role of transportation in regional development in conventional terms and I have nothing significant to add to his discussion. However, at several places he appears to display some concern that the structure of agricultural shipping and receiving firms may be modified by rate and service actions taken or under consideration by the railroads. Wisely, in my opinion, he fails to judge these actions as good or bad. As I mentioned above, value of service rate structures crumble with the onslaught of competing transport technologies, and many agricultural shippers were large enough already to adopt or threaten to adopt alternatives.

In discussing some of the competitive forces causing railroads to adjust their rates and services for agriculture, Nicholls cites the agricultural exemption as one factor. Miklius [2] failed to find unambiguous evidence that the agricultural exemption has really had an adverse effect upon the traffic available to railroads. More importantly, or so it seems to me, the agricultural exemption gave a truck transportation alternative to small-scale agricultural shippers and receivers at costs similar to those which large-scale shippers and receivers were able to achieve through contract or private trucking. The shift of traffic from rail to truck has likely been as great or greater for manufactured as for unmanufactured agricultural commodities, and much of this traffic moves by private or contract trucks rather than by regulated trucks [3].

Nicholls states that the actions by railroads to reduce coarse grain rates without similar reductions on grain products created an incentive for grain processors to relocate from grain producing to grain consuming areas. There is no question but that such incentive exists, but did it not exist prior to the actions of the railroads? Truck and barge movements of raw grain into the Southeast have existed a long time. Again, the railroad action must be characterized as an intermodal competitive move necessitated by the nearly complete attrition of the former rail monopoly in transport.

Finally, Nicholls states that ownership by the volume shippers of a substantial portion of the limited supply of railcars could adversely affect availability of cars to small shippers and receivers. I agree, but elsewhere I have hypothesized that the change in the per diem code of the Association of American Railroads in 1964 has removed much if not all of the disincentive prevailing prior to 1964 for railroad ownership of specialized, high cost cars to be used in interchange service [1]. Pat Boles of ERS and I are now engaged in research to determine if the 1964 change in the per diem code has resulted in any perceptible change of specialized car ownership trends existing prior to 1964. We hope to have reportable results in the near future.

Rust is quite correct in stating that Montana wheat producers can exercise much control over the seasonality of their demand for transport. The flexibility provided for them and for shippers by vast grain storage facilities may be the principal factor preventing freight car shortages of recent years from being catastrophic. The price risks borne by producers and shippers, nonetheless, are sizable. Unless means for shifting these risks through futures trading or forward sales can be exercised, producers and shippers likely will have seasonality in their transport demand.

The rate situation that Rust describes for Montana is in accord with what I would expect to find. Rail costs vary little with distance of shipment, while truck costs are composed almost entirely of direct line-haul costs. Thus, railroads serving long-haul landlocked areas are the last ones to encounter direct intermodal competition. In the absence of clear evidence that indirect effects will undermine their traffic base, the decisions of rail managers to continue to charge rates that will recover sunk costs cannot be condemned as irresponsible.

To conclude, it seems quite clear to me that advances in transportation possibilities of recent decades have had very significant income-transfer effects within our agribusiness economy. It is less clear to me that there have been equivalent resource-reallocation effects in our land-extensive agricultural economy. It is not at all clear to me that rate decisions of the railroads alone have had significant effects on either income transfers or resource reallocations within our agribusiness economy. The decisions have had effects on both income and resource allocations within our transport industry. Taken in this frame of reference, the significant contributions we as agricultural economists can make in the transport decisions of the future may be in initial stages of planning new transport systems. The rate decisions following the development of new possibilities are important, but the effects of the rate decisions may be primarily internal to the transport sector.

CONGLOMERATE TRENDS IN BUSINESS STRUCTURE

CHAIRMAN: RONALD O. AINES, INTERNATIONAL MINERALS AND CHEMICAL CORPORATION

Factors Underlying Business Interest in Conglomerate Mergers

ODIN WILHELMY, JR.

ANYONE who has been even reasonably alert to trends in American business in recent years is well aware that merger has become a way of life. There were an estimated 4,462 mergers in 1968, and the number in 1969 is expected to rise to 5,400 [2]. Over the past five years or so, a growing number of such mergers have been instigated by firms that have come to be known as "conglomerates."

Since different people have different ideas on what a conglomerate is, let me define the word as I will be using it in this paper. I am not talking about the more conventional forms of merger that have been commonplace for a long time—horizontal integration (such as occurs when one fertilizer company acquires another fertilizer company) or vertical integration (such as the purchase of a broiler operation by a feed manufacturer). Neither am I talking about diversification into related product areas (a soap manufacturer buying a bleach producer) nor into different geographic areas in the same product line. Rather, I will be talking primarily about mergers in which one company takes over or combines with another whose product line is completely dissimilar, such as an electronics firm acquiring a meat packer or a telephone company buying a vending machine company.

Conglomerates, even by the latter definition, have been with us for a long time. One need only cite such giants as General Electric, Ford, and Westinghouse to confirm this. However, these companies got that way long before the recent wave of acquisitions that have led to such well-known enterprises as Ling-Temco-Vought, Textron, Gulf and Western, and Litton, to name only a few. The fact that a number of major U. S. food and agricultural companies—Armour, Wilson, John Morrell, United Fruit, Allis-Chalmers, Canteen Corporation, Sunshine Biscuit, etc.—have been involved in such acquisitions (actual or threatened) makes this particular session of more than passing interest to agricultural and food economists.

ODIN WILHELMY, JR. *is with the Department of Economics and Information Research, Columbus Laboratories, Battelle Memorial Institute.*

Reasons for Conglomerate Mergers

The reasons for merger of a conventional sort are well established and accepted and generally rational in terms of both economic principles and good business practice. The overall reason for such combining of business enterprises is the conviction that bigger companies can operate more efficiently and more profitably and better serve the consumer than can small companies. The individual reasons underlying a particular merger will vary, but they all contribute in one way or another to this broad objective.

Diversification of a product line or into a different geographic area is one common reason for merger. When White Motor acquired the Oliver Corporation some years back, White broadened its product line—powered vehicles—into a new, but related, area. When Borden acquired other dairy companies, it broadened its market area.

Increased operating efficiency certainly is another good reason for merger. This increase may be effected at any of several levels. At the administrative level, it may permit the spreading of overhead costs over a broader production or marketing base through, for example, the combination of duplicate research, advertising, or public relations functions into single operations. At the production level, there may well be economies of scale achievable through merger that could not otherwise be obtained. Similarly, at the marketing level, a strong existing sales force in the field may well be able to take on the selling of additional, related products with relatively little increase in personnel or marketing costs. A good example would be the merger, many years ago, of the McGraw and Hill publishing enterprises.

A third specific reason that can be cited is the desire to apply particular know-how or capabilities developed in one industry to the business of another industry. For example, a strong research competence in a chemical company might well be a catalyst to significant growth in a steel company, if the former is brought into the fold and can contribute the benefit of its research strength. By the same token, established competence in consumer marketing can be the spring-board for a company dealing in one consumer product to move into other such products. Undoubtedly this was a major factor in the thinking of R. J. Reynolds and American Tobacco when they moved, by acquisition, into the food and beverage fields earlier in this decade.

These, then, are some of the conventional reasons—among many that could be cited—for merger in the normal sense. Let's consider now what are the reasons for conglomerate merger—bringing together in the same organization business firms that are completely unrelated to one another. Here the picture gets somewhat fuzzier.

Certainly there are a number of cogent reasons for conglomeration in the present-day American business economy. These have been highlighted both by executives of such firms in their public statements and by analysts of conglomerates who have been trying to figure them out. One obvious reason is that existing antitrust laws preclude further growth for many companies through conventional merger procedures. Until such time as a new set of laws is created to control conglomerates, this growth route represents a mechanism for expansion that doesn't put the company concerned in jeopardy of an antitrust suit.

Another significant basis for conglomeration is to spread the risks of business declines or drops in sales and profits that can occur in any product or industry at a given time. If you assemble a group of companies that are unlikely to be subject to cyclical ups and downs at the same point in time, you can minimize the effects of such cycles on the firm as a whole. As James Ling of Ling-Temco-Vought expressed it in a talk last year [5], "I made a vow that never again would any company for which I was responsible be dependent upon any one market, any one product, or any one technology." This, of course, is simply diversification—but to greater lengths than companies have tended to go in the past.

A third reason cited by conglomerates, as they move toward acquisition of a given firm, is that the target company, while well-heeled and solid as a rock, is being run by people who have become lethargic, unimaginative, and outmoded. The conglomerate promises to infuse it with new ideas, new blood, and up-to-date managerial techniques. Underlying this factor is one that is, perhaps, more basic. I refer to the intense personal ambitions of many business leaders. Building a conglomerate business empire represents a latter-day outlet for the same kinds of psychological driving forces that motivated military and political leaders like Alexander and Napoleon.

There is another set of reasons for conglomeration that arise from the current state of the U. S. economy—a state that has resulted from the recent steady growth of that economy, the accompanying inflation, the increasing complexity of business management, and the sophisticated new tools that have become available for coping with that complexity. In a paper at the NCR-20 Seminar in Kansas City this past April [3], A. C. Hoffman of Kraft Foods noted four of these factors encouraging the formation of today's large-scale enterprises and discussed each in some detail. They include (1) increased capital requirements, (2) capital formation, (3) risk taking, and (4) business management. Milton Leontiades, in an excellent paper in the *Financial Analysts Journal* the following month [4], carried the discussion a step further and noted three ingredients important in achieving superior management—a stong management information system, effective economic forecasting (for various pieces of the conglomerate), and dynamic long-range forecasting.

Since the brevity of this paper precludes any discussion of the four factors or the three tools that help ensure the quality of the business management factor, I will simply concur that these are increasingly essential to success in today's high-pressure business world. I also will agree that these are functions that may be performed more effectively in a conglomerate structure with its larger and broader base of operations—but the proof of the pudding here lies with the people running the operation.

In passing, I should note that conglomerates are *not* intended to provide centralized control of production and marketing activities of the component companies. There is ample evidence to date that these functions are being handled on a decentralized basis.

Evaluating the Results of Conglomeration

Given these reasons for conglomeration (in whatever mix they may occur in a given merger), one can well ask next: To what extent are these objectives being fulfilled, or likely to be fulfilled, in actual performance? This is difficult to judge at the present time. In its present form, the conglomerate idea is still relatively new, and for many such firms there simply hasn't been time to see how it will turn out. Compounding the problem is the fact that some of the financial devices used tend to obscure the true results of a given merger. (It is possible to generate an apparently improved profit picture simply by the manner in which the acquisition is consummated.)

In such a situation, perhaps all that one can do is to raise some pertinent questions, with the hope that answers will be forthcoming before too long. I'd like to do this—with emphasis on some groups of people who certainly will feel the effects of conglomeration one way or another, but who may have little or no influence on how the "deal" is accomplished or on what happens afterwards.

One such group of people are the managements of acquired companies, who may or may not have much to say in the matter. I am aware of one food company taken over recently where there was enough dissatisfaction at the middle echelon with the indecision prevailing at the top that a shake-up in top management probably would be welcomed. On the other hand, there have been instances in which a sizable number of top executives in the acquired company have been pushed out without apparent reason.

What about the stockholders who may have reaped the rewards of rising prices for their shares in the early days of the new firm but who now may be licking their wounds and wondering when their clever investment is going to stop losing value? You can bet that investors are going to be watching the conglomerates closely from here on, trying to sort out the good from the bad.

How about the customers of the component companies and the general public? Will they really benefit from the claimed greater efficiencies of the conglomerate companies, or will the latter find themselves unable to deliver? Finally, since I am in the research business, I wonder what the effects of conglomeration will be on the research activities and competence of the acquired firms. Certainly there will be efforts in some cases to upgrade the productivity of research staffs or to expand their sphere of operations to benefit all parts of the conglomerate. In others, however, the net result may be the opposite, and research personnel may look elsewhere for a job where the pressures are less intense.

Future Prospects

One may assume with reasonable certainty that merger in some form will continue as a way of life in American business. Whether those mergers will be increasingly in the form of conglomerates remains to be seen. One may also assume that food and agribusiness companies will be a part of this continuing merger trend—conglomerate and otherwise. Ron Aines in a recent paper [1] cited the chain of retail farm service centers being established by National Farm Stores, Inc., and Litton Industries in various Iowa towns—centers that will provide in a single location a wide variety of products and services for farmers.

While I can understand and appreciate the many reasons for the recent advent of conglomerates, I am still old-fashioned enough that I find more merit in the types of mergers that have prevailed over the years. To me, it makes good business sense for a fertilizer company to move into pesticides and then into application equipment and then into grain handling. It also makes sense for a feed manufacturer to get into broiler production or feedlot operation. I also see merit in a tobacco firm with its consumer marketing skills getting into the food business and applying those same skills there. I can even sympathize with some of the farm co-ops considering going into food retailing on a large scale. All of these more or less "conventional" methods of business expansion strike a more responsive chord in me than conglomeration among totally unrelated businesses. But perhaps I, along with a lot of other people in this country, are going to have to relinquish such outmoded ideas or be swept aside by the conglomerate movement.

In closing, I'd like to mention one problem area in which conglomeration may be the answer, namely, the upgrading of the food and agricultural situation in developing countries. For years now, we have heard and read of the multifaceted nature of this problem—the need to provide fertilizer, seed, irrigation, improved roads, better storage facilities, modern food-processing plants, refrigeration, adequate marketing arrangements, a market news service, credit, and so on. Perhaps this is one place where a conglomerate, either actual or in effect, would be the best way to solve the problem.

Firm Conglomeration as a Market Structure Variable

WILLARD F. MUELLER

BUSINESS conglomeration is not new. There have long been examples of multimarket and multiproduct business enterprises, the distinguishing features of the conglomerate firm. What is new, and what makes business conglomeration a timely public policy issue, is the profusion and enormous size of many contemporary conglomerate enterprises. Today most huge industrial enterprises straddle numerous industries, often doing only a small share of their total business in any one industry. Hence, conglomerate enterprises are no longer the exception, but the rule, in many contemporary industrial markets.

This development is of no lesser significance than was the replacement of many highly fragmented, small business industries by oligopolistic, big business enterprises beginning with the great merger movement around 1900. Economists responded to the new industrial structure emerging from that era by developing the theory of monopolistic or imperfect competition, and, ultimately, the body of price theory now encompassed by industrial organization theory.

The multimarket character of the modern conglomerate enterprise raises a number of important questions regarding the relevance of contemporary industrial organization theory and empirical research. The conglomerate enterprise may enjoy economic power that differs from the traditional market-oriented concept of market power. According to traditional theory, market power is derived from the characteristics of a particular market, especially the level of seller concentration, the extent of product differentiation, and the condition of entry. In this theory, market power is shared—e.g., in the form of higher prices and profits—by the sellers in the market at the expense of buyers. Conglomerate-derived power, on the other hand, differs from traditional market power in important ways. It depends upon intrafirm structure—particularly upon a dissimilarity of intrafirm structure among the companies that may be rivals in a particular market—rather than solely upon the structure of that particular market.

The most immediate effect of conglomerate power is the advantage it gives over rivals rather than over buyers. But ultimately it can work to the disadvantage of buyers because it may weaken or repress rivals, in-

---

WILLARD F. MUELLER *is Vilas Professor of Agricultural Economics at the University of Wisconsin.*

duce defense reactions by them, and discourage entry by new firms. Thus, conglomerate power can restructure particular markets by placing new restraints on the behavior of existing firms, by changing market shares, or by raising entry barriers.

Today I shall discuss briefly three market conduct options unique to conglomerate firms and not adequately explained by traditional industrial organization theory: business reciprocity, cross subsidization, and conglomerate interdependence and forbearance.

Business Reciprocity

Business reciprocity, simply defined, is the act of taking your business to those who bring their business to you—many would say that it is no more than doing business with one's business friend. But this misses the point. Buying and selling decisions guided by industrial "friendship" are a symptom of market power when the firm uses its market position in one market to expand its sales in another.

Reciprocity permits the seller to make a sale that it could not otherwise make or could make only at greater costs. Thus, reciprocity flows from "imperfectly competitive" or "oligopolistic" markets. In highly competitive markets, there is no need to engage in reciprocity or other business strategies to expand sales. But as markets become concentrated, individual firms recognize their interdependence and refrain from price rivalry, with the result that prices are maintained above marginal costs. Since open price competition in these industries tends to "spoil" the entire market, prices are "administered" and nonprice competition becomes the order of the day. In this market setting the oligopolist thus seeks the most attractive —and from his standpoint, the most economical—form of nonprice competition. He has a variety of forms from which to choose, including product differentiation, product development and innovation, advertising and promotion, tying arrangements, and reciprocity. Which of these forms he ultimately selects depends upon certain legal and economic considerations.

But before an oligopolist may include reciprocity among his alternative sales strategies, certain necessary conditions must be met. Most importantly, an enterprise must purchase goods and services from companies that are also its potential customers.

The volume of sales that may be influenced by reciprocal trading depends on the number, volume, and types of products purchased and sold. A single-line producer is bound to have fewer opportunities to use the practice. Similarly, producers selling only consumer goods are unlikely users because their suppliers of raw material and components absorb only minimal amounts of consumer goods.

The firms that have the greatest opportunities to engage in successful reciprocity are those that buy and sell a large number and volume of industrial products. This, of course, describes many of the large diversified industrial corporations of today.

Reciprocity introduces an alien factor in the competitive process, one superimposed on the normal elements governing market transactions in which goods are bought and sold on the basis of price, quality, and service. In a purely competitive market, the individual firm has no control over supply-and-demand conditions and in these markets reciprocity would have a negligible influence on industrial performance. Reciprocity becomes a serous anticompetitive influence when it bypasses and distorts the competitive process. In this respect it resembles other nonprice forms of competition, such as promotion designed to differentiate products and shield them from price competition. But unlike promotional efforts that can increase the velocity of trade, and sometimes the aggregate sales of particular products (as distinguished from the sales of a single firm), reciprocity merely rechannels trade in favor of firms able to exert reciprocal market power. In oligopolistic markets where price, quality, and service tend to become stabilized, reciprocity can become the decisive factor in shaping the market. If carried to its ultimate, the practice would result in closed-circuit markets that would exclude medium or small factors. Thus, oligopoly would be magnified in a sort of circular integration fashion by which purchases of the leading firms would be tied to sales, foreclosing the opportunities of firms without substantial conglomerate power.

In sum, reciprocal selling may (1) distort the exchange process, thereby stimulating more rigid price structures and misallocation of resources, (2) increase market concentration, thereby endangering long-run industrial performance, and (3) raise barriers to entry, thereby reducing the salutary effects of potential competition. The net effect of extensive reciprocity may be to centralize manufacturing resources and decision-making in the hands of a relatively few firms.

Although I shall not discuss here the empirical evidence of the extent and consequences of reciprocal selling in the economy, recent antitrust cases and investigations reveal that its use has grown in importance as firms have become more conglomerated.

Cross Subsidization

Cross subsidization is the ability to offset losses in one profit center by means of income generated in other profit centers. The ability to practice such subsidization depends upon the characteristics of a firm's diversification compared with those of its competitors and upon the structure of the various markets in which it operates. If a large multimarket firm operated only in a series of competitive markets, it would earn no "excess" profits that could be used to subsidize expansion in other markets. On the other hand, when a substantial part of a large conglomerate firm's operations is lodged in highly concentrated industries, it is likely to earn profits above competitive levels. The greater its "excess" profits, the greater its ability to subsidize with internally generated profits its strategies to enter, condition, expand, or defend particular markets.

Some economists argue that large absolute size, quite apart from market power in particular markets, confers market power on a firm. Other economists reason that unless the conglomerate firm possesses market power in some markets, it cannot have an advantage over its smaller, less diversified rivals. Economists generally agree, however, that if a multimarket firm possesses market power in some markets, it may become a vehicle for the achievement of market power elsewhere. Quite clearly, any advantage inherent in large size and conglomeration will be magnified when the firm possesses market power in some of its operations. For, if a large multimarket firm occupies substantial market positions in some of its product or geographic markets, it may use the profits derived there to subsidize its attainment of market power elsewhere.

Firms practicing cross subsidization may enhance their profit opportunities by restructuring a market or by modifying conduct within it. The affected market can be restructured by increasing its level of concentration and/or its domination by conglomerate firms, with a concomitant raising of entry barriers. Conduct can be modified, for instance, by introducing new or more intensive use of marketing techniques, e.g., advertising and promotional activities, as well as by price cutting. The nature of the barriers to entry can be changed by conduct that gives new emphasis to marketing expenditures or by conduct that intimidates potential entrants by the ability to concentrate the resources of the diversified firm in any particular market. A diversified firm that uses its conglomerate power to restructure an individual market can also use such power to defend the restructured market. The threat resulting from the potential use of such power can transform this defensive readiness into a barrier to entry. Such conduct tends to limit potential entrants to other conglomerate firms, which, when not deterred by conglomerate mutual interdependence and forbearance (as discussed below), may further restructure the market as it becomes increasingly dominated by conglomerate firms.

The ability to pursue tactics financed by cross subsidization does not necessarily injure competition, nor do those engaging in the practice necessarily do so with predatory intent. The effects depend upon the structure of the affected market and the nature of the competitors, actual and potential, operating in the market. Indeed, there are market situations where the ability to cross subsidize is an imperative of entry. This is true in industries with high "start up" costs or "break in" costs. The latter situation may obtain when existing firms enjoy a product differentiation advantage or conglomerate power. If entry into a market were free, a firm would have no incentive to restructure the market through cross subsidization tactics. For even if a monopoly were attained, it would have gained no permanent surcease from competition because new entrants would flood the market should the monopolist charge above competitive prices. But in modern industrial markets, entry is seldom so free that potential entry alone forces oligopolists to price at competitive levels. Moreover, the mere presence of firms with conglomerate power ready and able to rebut a price-cutting entrant may itself create a formidable barrier to entry. As Robert C. Brooks has observed, "... knowledge that an existing firm is ready to engage in predation, and that such predation would inflict losses on the victim, would itself serve as a barrier to entry."

I shall not here attempt to demonstrate the ways in which cross subsidization is influencing contemporary industrial structure conduct and performance. But there is no doubt that many firms possess the power to engage in this practice, and that this power is frequently exercised—for good or ill.

Conglomerate Interdependence and Forbearance

Oligopoly theory, a la Chamberlin, teaches that when sellers are few they tend to behave interdependently in making their price, output, and other market decisions. As a result, in highly concentrated markets sellers behave more like monopolists than competitors.

This accepted theory of oligopoly explains the behavior of firms in a single market where their discretion in pricing is constrained solely by certain structural characteristics of that market. Useful though this theory is in explaining many aspects of industrial behavior, it is inadequate in explaining certain important behavioral characteristics found in contemporary markets. The multimarket characteristics of firms may result in conglomerate mutual interdependence and forbearance among actual and potential competitors—an interfirm relationship that differs from traditionally viewed ologopolistic interdependence.

Conglomerate interdependence and forbearance can arise because (1) the same or related decision makers have simultaneous access to both firms, or (2) the firms share contact points in input or output markets that create a mutual awareness of common interests. Interlocking directorates, intercorporate stockholding, joint ventures, and a whole spectrum of institutional arrangements encouraging the creation of a community of interests represent the first set of factors that facilitate coordinate relationships among firms. Firm structures, i.e., their size, diversification, and positions in various markets, constitute the second set of factors that create a commonness of interest. Conglomeration, by increasing both size and diversification, increases the number of contact points shared with competitors, suppliers, and customers, thereby increasing the mutual awareness of common interests among firms that share the points of contact.

The simplest form of conglomerate interdependence probably involves pricing decisions. Firms that meet as competitors in many markets are likely to regard one another with greater deference than if their decisions were constrained solely by what happened in a particular market. The resulting mutual forbearance in making pricing decisions results because conglomerate rivals are less likely to push their advantage in one market lest their conglomerate rivals retaliate in others.

Although conglomerate mutual interdependence is most obviously manifested in price decisions, it may take more subtle forms. Records in various antitrust proceedings provide rich evidence that, when corporations become large and conglomerated, they tend to accord special treatment to other large national and even international corporations.

Again, time does not permit documentation of the extent and consequences of shared contact points among contemporary conglomerate enterprises. But I am confident that interdependence and forbearance flowing from such shared contact points leads to the consideration, proposal, and realization of acts that affect market shares, entry, and pricing practices. Such conglomerate interdependence has more global implications for industrial behavior than the traditional concept of oligopolistic interdependence.

Conclusion

Quite clearly, I have been discussing matters that differ from traditional oligopoly theory predicated on single-product, single-market firms. What I am suggesting today, therefore, is that our changing industrial environment demands a broadening of the theoretical framework used in analyzing much of our contemporary industrial scene. Simply put, probing many real world problems calls for according firm conglomeration independent status as a market structure variable. Only by doing so can economic analysis make a relevant contribution to many of our most pressing public policy issues.

Perhaps I have disappointed those who had expected me to address myself to the topic originally assigned me by your program chairman, namely, the public policy issues involved in the current conglomerate merger movement. That is a topic dear to my heart and to which I shall shortly address myself elsewhere. What I am urging today is an extension of the argument that Bob Clodius and I made just before I came to Washington eight years ago. At that time we urged that agricultural economists should make greater use of market structure analysis as an orientation in their research [1]. The rich body of empirical industrial organization research done since then argues persuasively for a continued use of

Conglomerates: Economic Conduct and Performance

Albert G. Madsen and Richard G. Walsh

> Perhaps all that is not performance is preparation, or performance that shall be.
> —Ralph Waldo Emerson

THE words which have been used to specify this discussion—conglomerates, economic conduct, and performance—no doubt evoke in each of our minds different meanings, different values, and a different set of facts as to their relationship. The purpose of this discussion is to explore what common ground actually exists and what real differences we have. What are the alternative meanings of each of these words? What is the state of knowledge with regard to the effects of conglomerates on economic conduct and performance?

Significance of Our Terms

By reference to a conglomerate, rather than to a diversified, multi-market or multi-product firm, the subject is already loaded. Managers of diversified firms often seek to avoid use of the word, believing that it denotes a lack of inner logic. In this view, a true conglomerate produces products or services of several industries that are related only with respect to managerial and financial functions or economies, but not with respect to product development, purchasing, production, or marketing. We are advised to use the less emotive terms, such as diversified, multi-market, or multi-product, for firms related in the latter ways. By this definition, only eight of the 200 largest U. S. corporations qualify as conglomerates. Notably absent from the list are such multi-product giants as General Motors and General Foods.

Product relationships are, of course, a matter of degree, and opinions may differ concerning whether those within a diversified firm are significant. However, to most economists the term conglomerate has gained too wide a usage to be nearly defined away. We see the term as encompassing most large corporations as special kinds of firms that "operate in two or more separate product and/or geographic markets" [18, p. 3]. This reflects the value we place on the economic theory of the firm. By this definition, virtually all of the 200 largest corporations are conglomerates, as are the 50 largest food manufacturers and the large retail food chains that operate across many product and geographic markets.[1]

---

[1] Mueller suggests that several large retail food chains possess the basic characteristics of the conglomerate enterprise. They are much larger than their competitors,

---

Albert G. Madsen *is associate professor and* Richard G. Walsh *is professor of economics at Colorado State University.*

The most important, and widely held element in the definition of a conglomerate reflects the fact that its conduct is not subject entirely to the competitive discipline of any one market. However, economists differ as to the nature and extent of the advantage this confers. Some reason that, unless the conglomerate firm possesses market power in some market, it cannot have any special advantage over its smaller, less diversified rivals [20, pp. 19, 44, 46, and 202–210]. Most economists would agree that if a multi-market firm does possess market power in some markets, such power may become a vehicle to achieve market power elsewhere.[2] It may use the excess profits derived in such markets to subsidize its expansion elsewhere.

Market conduct has been emphasized by those most critical of conglomerates [6, pp. 331–360]. Of special concern are the practices of: (1) deep pocket subsidization or promotion of operations in one market out of profits from another; (2) reciprocity or purchasing decisions designed to increase sales; (3) full-line or tie-in selling of multi-products; and (4) forebearance as firms meet in several different markets. Critics not restrained by long conditioning to an economic theory that values a market economy above all else still find ample imperfections in the behavior of conglomerates with respect to stock promotions. Indeed, some observers see economic conduct of conglomerates with respect to the stock market, financial, and accounting procedures as far more important than product market conduct. It should be readily apparent that the scope of our treatment of conglomerate behavior is limited by the meaning we assign to the term.[3]

---

operate across a large number of separate economic markets, occupy much larger positions in some market than others, and the largest retailers meet one another with increasing frequency in their respective markets [17, p. 1865].

[2] This is where our concern with conglomerate or overall concentration is related to industrial or market concentration. The 50 largest food conglomerates, with nearly 50 percent of the assets in food manufacturing, held over two-thirds of the top four firm positions in the 40 food industries. They are most important in the most concentrated food industries. This is significant because profit rates are much higher in the highly concentrated food manufacturing industries than in the lower moderately concentrated ones. Food manufacturing firms operating in industries with concentration ratios exceeding 60 percent enjoyed average net profit about 60 percent above those in industries with four-firm concentration ratios between 40 and 50 percent, and over 100 percent greater than those in industries with concentration ratios below 40 percent [20, p. 3].

[3] For more than three-quarters of a century, Congress has cast a critical eye on large conglomerate corporations with respect to the nonmarket uses of power. Their large size has been associated with undue political strength, legal harrassment, and public relations (subsidizing studies and buying their own reputations). Other observers less critical of conglomerate market behavior often emphasize those types of economic conduct that are internal to the firm. In this view, most practices of conglomerates are just good business management. Falling into this category are efforts to minimize the costs of new product introduction, risk, taxation, research, management overhead, finance, etc.

The economic performance of conglomerates refers to the results of their economic behavior. Society is concerned with how conglomerates perform in terms of efficiency, profit levels, selling costs, product quality and variety, and progressiveness. These variables are drawn from partial equilibrium analysis. There are more general criteria such as the contribution of conglomerates to economic stability and growth. Some have questioned their contribution to many of the most pressing problems of the day—water and air pollution, job retraining, urban and rural poverty, preservation of our natural resources, promotion of basic research, to name a few. Thus, the significance we assign to the performance of conglomerates is related to our choice of variables to be included in the analysis. All students of the subject are not in complete agreement.

Economic Conduct of Conglomerates

The economic historians among us will find in the archives considerable documentation of noncompetitive behavior of conglomerate firms. For example, the large meat packing conglomerates of the late 1800's and early 1900's engaged in collusive arrangements with regard to fixing beef prices, division of territory, division of public contracts, and compulsion of retailers to buy beef from certain packers [21, p. 6]. Many other conglomerates of this period behaved in ways equally as disruptive to the competitive system.

The fact that meat packing companies were engaged in such diversified businesses as operating service companies, developing land, operating stockyards, canning, banking, publishing, etc. [8, pp. 45–47], gave them considerable market power, clearly recognized and respected by one another, and led to unified actions. However, an important factor that led to considerable forebearance in competition among the large packers, as early as 1917-18, was their joint ownership of 108 companies [21, p. 6]. Pressures for competitive forebearance today arise more from reciprocal trading, without the type of overt collusion that was evident among early conglomerates. As early as 1930, important reasons for the government arguing against relaxing the Packers' Consent Decree was the willingness of the "petitioners" to employ collusive and coercive tactics in competition and to use their dominant positions in certain lines to promote their interest in others [2, p. 101]. Some fear that similar behavior may arise from present day conglomerates.

The methods by which conglomerates have promoted good will and encouraged the public to purchase their stock during the recent merger movements are reminiscent of those that led to serious problems in the past. The practice of manipulating reported earnings (increase the earnings per share) without disturbing or increasing the production capacity or the efficiency of the company warrants concern. The firms initiating the mergers have been able to achieve this by paying for the acquired firm's stock with their higher priced stock. The result is a smaller number of shares in the hands of all stockholders in the combined company. Even though the total earnings of the conglomerate may be identical with the total earnings of the two companies before the merger, the earnings per share would reflect a growth. These earnings have then been publicized to attract stock investors who have bid up the price of conglomerates' stock [9, p. 81]. The economy has not become any richer. A second method used to "puff" the earnings statements of aggressor conglomerates is to use the "pooling of interest" method of accounting and then to sell some of the assets acquired when new firms are taken over [9, p. 180].

Reciprocal trading has long played an important part in doing business in our capitalistic environment. However, there is increasing antipathy toward the practice under the present trend in business size and conglomerate organization. An effective way to gain the friendship and goodwill of a possible customer is to buy some of his products. The popularity of such arrangements is the fact that industries dominated by big companies have purchased from one another for years. McCreary & Guzzardi estimated that in 1965 about 60 percent of the companies on Fortune's list of the 500 largest industrialists employed "trade relations men" whose functions were in part to conduct reciprocal dealings [15, p. 81].

Although there are nearly infinite opportunities for reciprocal trading among large conglomerate firms, this is more clearly demonstrated by observing possible buying and selling arrangements between two such firms, for example, Olin Mathieson with 10 product divisions and Textron with 37 divisions [10, p. 170].[4] We do not know that these specific conglomerates trade in reciprocal fashion, but the conglomerate structure of these companies does seem to provide opportunity for close working relationships, and this example demonstrates the extent to which forebearance may be encouraged. There is the possibility of vigorous competition between such firms in many markets but can this competition be effective where significant reciprocal trade relations exist?

We have discussed only one aspect of the problem—that of competition between large conglomerates. A more damaging consequence of reciprocity may be the formidable barriers to entry for small or less diversified firms. In selecting suppliers, the standard may become "which supplier is one of my best customers," rather than "what firm can provide the specific item at the lowest cost, yet meet required service and product standards."

---

[4] There appears to be the possibility that all 10 divisions of the Olin Mathieson Company could utilize the products of one or more Textron division. On the other hand, without benefit of company records, it seems that at least 24 Textron divisions could use products of Olin Mathieson and that 12 divisions of Textron make products which could compete with the products of Olin Mathieson.

An example of how close trade relationships between conglomerates have dampened or even killed off competitive actions is documented in a report of the National Commission on Food Marketing [19, p. 413]. Consolidated Foods, a food manufacturer, and retailer, cut prices in its seven supermarkets in Chicago. National Tea Company, a large food retailer reacted by refraining from buying Consolidated's products for a week. Consolidated quickly returned to regular prices and somewhat later sold its Chicago retail food stores.

Another practice of the large conglomerates is to use their "long purse" in disciplining competitors. There is evidence that firms possessing such power have utilized it. For example, in 1954-55 Safeway engaged in a price war in the Dallas and El Paso market areas to combat trading stamps. Since Safeway is a multi-market firm and handles multi products, it was able to subsidize deep price cuts in these more competitive markets with above normal profits from less competitive markets. Government counsel Margaret Brass, in the summation of the case, stated that Safeway, by its below cost selling operations, had sustained a 15-month loss of about $4 million in the two divisions together [26 pp. 73–74]. The conclusion of the FTC was that Safeway was quite willing and able to utilize competitive tactics that resulted in substantial losses in one of its major divisions over a significant period of time, without suffering a serious adverse effect on its overall profit performance [7, pp. 84–90].

Economic Performance of Conglomerates

Galbraith argues that large conglomerates may contribute more to the growth of the economy because of their superior managerial, technological, and financial strength. According to this view, most of the growth of large conglomerates has been internal, through the construction of new plants and equipment and market expansion. Indeed, the primary reason the share of total manufacturing assets held by the top of 200 corporations grew from 48.1 to 54.2 percent, 1948 to 1960, is due to this superior economic behavior. While this view may have squared fairly well with the facts during the early postwar years, it appears to have been wide of the mark during the decade of the sixties. Merger activity by the 200 largest corporations accelerated during the 1960's. Between 1960 and 1967, their share of total manufacturing assets grew from 54.2 to 58.7 percent. But after the acquired assets are subracted, their share for 1967 was 54.4 percent, essentially the same as in 1960 [11, p. 79]. And this is probably a minimum estimate of the importance of mergers to their growth since it does not take into account the postmerger growth of acquired assets. Without mergers, their growth rate would have fallen below that of smaller firms. Thus, during the past decade, the largest 200 conglomerates appear to have had a negative effect on the economic growth of the economy. For mergers by themselves have added no output to the economy, no new employment, nor new plant construction.

Conglomerates may be especially able to take an inefficiently managed division and turn it around. Potential social gains from improved production efficiency may be substantial. This is what Leibenstein [14] has termed X-efficiency and illustrated with a large number of worldwide case studies showing realized efficiency gains frequently above 25 percent of unit costs.[5] The empirical evidence, while far from exhaustive, suggests that many firms have not been operating on their production frontier and would respond to improvements in general management, plant layout, personnel, production procedures, selling organizations, and budgeting and accounting systems.[6]

Large conglomerate corporations have had higher profits in the past than all U.S. manufacturing firms. Weston analyzed the financial performance of 58 multi-industry firms over the nine-year period, 1958 to 1966.[7] Earnings per share grew 10 percent a year versus 6.7 percent for all firms in Standard and Poor's stock index. Stock prices at each year's high rose 10.5 percent a year against 5.4 percent for the Dow-Jones industrial average. In 1967, conglomerates had average profits of 12.6 percent of net worth compared with 11.9 percent for all manufacturing firms.[8] Often high profits are justified as a reward for the risk associated with highly varying profit levels. However, conglomerates that combine operations in several markets or industries, will experience less risk. This is the standard gain attributed to portfolio diversification or to farm enterprise diversification. The importance of this is that a reduction in the premium for risk is equivalent to a cut in the conglomerate's costs. This would increase social welfare if effective competition in the conglomerate's markets resulted in an equivalent reduction in the prices of its products. That this is not often the case is shown by Conrad and Plotkin [4, p. 40], for the more stable (riskless) profit levels are associated with high profits.[9]

---

[5] It is significant to contrast X-efficiency with multi-plant efficiency. T.R. Savings [24] estimates that in relatively rare instances, efficiency gains of three to five percent of costs were available to multi-plant firms.

[6] Have these potential improvements in efficiency been realized? It is instructive to consider the relationship between productivity and industrial concentration. Large conglomerates occupy a disproportionate share of the top positions in the more concentrated industries [11, p. 49]. A recent National Industrial Conference Board study showed that, on the average, the largest four companies in an industry had higher rates of productivity than the remaining companies in the same industry and that industries with the highest productivity tended to have high concentration ratios, while those with low productivity tended to have low concentration ratios [1, p. 4]. Productivity was defined in terms of shipments per employee or value added per employee, the former explaining about six percent of the variation in industrial concentration and the latter explaining 20 percent. The reason many industries are relatively unconcentrated, of course, is that capital requirements for entry are very low. Often such industries are relatively labor intensive and for this reason have relatively low shipments or value added per employee, the measures of productivity used in the study. When these data were re-run for industries with four-firm concentration of 35 percent or over, there was a higher simple correlation between value added per employee and the Collins and Preston [3] cost-price margin ($R^2 = .36$) than between value added per employee and concentration ($R^2 = .09$). This strongly suggests that value added per employee, which has been used as a measure of productivity, is in fact a better measure of profitability and promotional costs. However, after profits and advertising were taken into account in a multiple correlation analysis, there was no relationship between value added per employee and industrial concentration [16].

[7] As quoted in [12, p. 48].

[8] The 50 largest food conglomerates owned nearly half of the assets in food manufacturing and earned 60 percent of the profits. The 78 companies with assets of

The progressiveness of conglomerates in the invention of new products and the innovation of new processes is subject to two contrasting views. First, it is maintained that only large conglomerates are able to finance the research and development needed to invent new products and to coordinate the complex activities required to introduce them in national distribution. Moreover, high conglomerate profits enable them to finance more research; and, to the extent conglomerates avoid price competition, they emphasize nonprice competition through new and improved products. A second view is that large conglomerates are not essential to discovering and introducing new products [11, p. 64]. Large firms often resist the introduction of major new products and processes because of investments sunk into existing product facilities. Institutionalized inventions at large corporate research laboratories are unlikely to generate significant deviations from conventional products and practices. There have been a

---

over $1 billion in 1968 held 43 percent of all assets in U. S. manufacturing and earned 49 percent of the profits [11, pp. 47–49]. These higher profits may be justified as merely a private transfer from single industry oligopolists to multi-industry conglomerates, with no social gain or loss. Beyond this, conglomerates are more likely to possess the retained financial resources needed to enter additional highly concentrated high profit industries, virtually closed to new firm entry. Oligopolists in these industries will, as a result, tend to behave more competitively than before in pricing their products in the hope of deterring the potential competition of the conglomerates. But we are deluding ourselves if we think that the potential competition of conglomerates is equivalent to new firm entry. This is because conglomerates tend to have a higher profit objective than most American industries realize [13]. Critics have pointed out that the capital bottled up by conglomerates in search for high profit opportunities is unavailable for many socially worthwhile investments such as low income housing, which may have lower returns than conglomerate profit objectives.

[9] Analysis of the relationship between level of profit and inflation shows how conglomerates' excess profits have contributed to the inflationary spiral. For example, when manufacturing profits average 10.1 percent of net worth, we may expect an annual inflation rate of only one percent. When profits rise to 14.6 percent, the inflation rate rises to three percent [22, p. 109]. These calculations are based on an equation that assumes unchanged unemployment rate at four percent, unchanged income distribution and labor force distribution, and appropriate relative price shifts, with wages in all sectors of the economy changing at the same rate as those in manufacturing and a three percent rate of productivity growth.

large number of empirical studies in recent years.[10] While there is not complete agreement, Scherer concludes that "these findings . . . raise doubts whether the big, monopolistic, conglomerate corporation is as efficient an engine of technological change as disciples of Schumpeter (including myself) have supposed it to be" [25, pp. 1121–22].

This raises an important question concerning the selling costs of conglomerates. Do the requirements and advantages of large-scale advertising, rather than technology, give large conglomerates a special advantage? Table 1 shows the number of products added by 25 leading food

Table 1. Industrial entry and exit by 25 large food conglomerates, 1950 to 1966

Firm	Number of different industries[a]

[10] Students of the problem owe a debt of gratitude to the Senate Subcommittee on Antitrust and Monopoly and its chairman, Senator Philip A. Hart (Michigan), for the exhaustive hearings it has held on the subject of the role of technology and industrial organization. These hearings have reviewed nearly all of the recent authoritative work on this subject [5].

manufacturers through acquisitions between 1955 and 1966. These food conglomerates were in 109 different industries in 1950, and by 1966 they had dropped 8 of these while adding 108 more, 90 percent by merger. This suggests that product diversification by these large food conglomerates doubled in a decade, not because of their superior research ability, but through merger. Table 2 shows that for brands acquired by the 25 large food conglomerates, advertising support was nearly doubled in the first full year after acquisition, from $22.7 million to $43 million.[11] As a result, there has been an increasing concentration of food advertising expenditure in the large conglomerate [20, p. 68]. While advertising as a percent of sales remained almost constant for small food corporations between 1947 and 1961, the largest food conglomerates more than doubled their spending on advertising relatives to sales. The largest food conglomerates spend relatively more on advertising than smaller companies and, because of volume discounts and other advantages, this spending results in more advertising impact.[12]

Table 2. Changes in level of conglomerate advertising support provided brands when acquired, 1950 to 1964

Year	Network TV	Spot TV	Magazines	Newspapers	Total
	million dollars				
Year prior to acquisition	5.4	7.9	6.2	3.2	22.7
First full calendar year after acquisition	7.9	17.1	8.2	9.8	43.0

Source: [20, p. 126].

Finally, it seems clear that large conglomerates are able to engage in competitive strategies not open to lesser enterprises. We have illustrated the fact that increasing conglomeration raises several important economic problems. It can short-circuit the "market test" upon which we rely so heavily in an effectively functioning market economy. But there are two sides to every coin. Large conglomerates are able to undertake product promotion tasks that would exhaust the resources of smaller concerns and thereby may improve industrial performance. It is imperative that we develop more and better understanding of the nature and significance of large conglomerates. This will require much more study and reappraisal of the problem in the years ahead.

---

[11] Williamson has hypothesized that "an efficient procedure by which to introduce new products is for the initial development and market testing to be performed by small firms (perhaps new entrants) in an industry, the successful developments then to be acquired, possibly through merger, for subsequent marketing by a large, multidivision firm" [27, pp. 1115–16]. For a contrasting view of mergers, see Reid's findings [23, p. 1922] that the more actively firms merge, the more they tend to further the self-interests of managers rather than the interests of stockholders.

[12] This favorable treatment constitutes an important scale advantage for the large conglomerate. An advertising executive reported that large conglomerates, such as General Foods, would get their TV advertising at a cost of $2.50 per thousand households, while smaller advertisers would have to pay $3.50 to $4 for the same audience. This means that smaller advertisers would have to pay 40 to 60 percent more for the same coverage [20, p. 70].

Pricing Milk in Federal Order Markets*

JEROME W. HAMMOND AND TRUMAN F. GRAF

TWO types of price series are used as the basis for pricing most of the approximately 54 billion pounds of milk regulated by federal milk orders in this country. They are: (a) *product price formulas,* which are calculated by multiplying prices for manufactured products, such as butter and non-fat dry milk or cheese, by yield factors and deducting a manufacturing allowance; and (b) *competitive pay price series,* which are prices paid farmers for manufacturing grade milk at non-regulated manufacturing milk plants.

Competitive price series that have been used include the "Midwest condensary" price, "local plant" averages, "U.S. average 3-product manufacturing grade milk" price, and the "Minnesota-Wisconsin" price.

The Minnesota-Wisconsin price series is most widely used. It is the basis for Class I prices in all but six of the 67 Federal milk orders in the country and is a factor in determining surplus class prices in about two-thirds of the federal milk order markets.

However, its validity has been questioned by various factions in the dairy industry. A difference of as little as one cent per hundredweight either way could alter farmers' milk receipts, by close to $5 million annually in federal milk order markets alone. Therefore, an analysis of this price series was felt to be of great importance. This paper summarizes such an analysis.

Representativeness of the Minnesota-Wisconsin Price Series

The sample of plants used in calculating the Minnesota-Wisconsin price series is designed to include a representative group of plants purchasing manufacturing grade milk in both states. If the sample is in fact representative, the announced Minnesota-Wisconsin price should closely approximate the average of prices reported paid at all manufacturing grade milk plants in the two states.

The analysis indicated that the Minnesota-Wisconsin price series is a good estimate of the final average reported prices. For the 77-month pe-

---

* This paper is based on two previous publications by the authors [1, 2].

JEROME W. HAMMOND *is associate professor of agricultural economics at the University of Minnesota.* TRUMAN F. GRAF *is professor of agricultural economics at the University of Wisconsin.*

riod, August, 1961 through December, 1967, the two prices were the same in 12 months and differed by one cent in 35 months. The maximum difference for the period was seven cents. For the entire period, the simple monthly average of final average reported prices in the two states exceeded the Minnesota-Wisconsin price series by .6 cents per hundredweight. Thus, the Minnesota-Wisconsin price series is quite representative of reported prices for Minnesota and Wisconsin.

Accuracy of Reported Prices

Although Minnesota-Wisconsin series prices are representative of average prices reported by all manufacturing grade milk plants in the two states, the charge has been made that the prices reported by plants are different from those they actually pay their producers. These differences can occur because of errors in butterfat testing and weighting, gains or losses on milk hauling by the plant, or the payment of patronage refunds by cooperatives after prices have been reported. The effect of each of these factors was measured in 52 representative Minnesota and Wisconsin manufacturing grade milk plants (26 in each state).

Butterfat Testing.—Results of this analysis indicated that 25 of the 26 plants in each state paid for less butterfat than they received from farmers and therefore quoted higher prices than were actually paid. Average understating of butterfat tests for sample plants was 1.76 percent in Minnesota, 1.38 percent in Wisconsin, and 1.56 percent in the combined states.

The average "overstatement" of milk prices, because of understating butterfat tests, was 4.4 cents per hundredweight in the Minnesota plants surveyed, 3.8 cents per hundredweight in the Wisconsin plants, and an average of 4.1 cents per hundredweight for all 52 Minnesota and Wisconsin plants.

Low paying plants overstated their price more than did high paying plants—five cents per hundredweight for low paying plants, compared with 3.9 cents for high paying plants in the two states combined. *Thus, upward bias in reported farm milk prices resulting from butterfat test error was not due to greater overstatement of price by high paying plants than by low paying plants. Instead the opposite situation prevailed.* Discrepancies exist between the amount of butterfat plants purchase from the farmers, and the amoung of butterfat they pay farmers for. The reason may be dishonesty or the highly technical nature of determining fat content or both.

Milk Hauling.—Profits or losses on milk hauling also influence prices received by milk producers. For example, if a plant incurs a loss on hauling, it is in effect subsidizing the producer on his hauling costs; therefore, reported prices will be lower than actual prices.

The average loss on hauling for all plants surveyed was 1.4 cents per hundredweight. Thus, on the average, producers were being subsidized by that amount, with the result that reported prices were 1.4 cents per hundredweight lower than actual prices paid.

Plants with highest pay prices were making an average profit of .3 cents per hundredweight on hauling. Reported prices by high paying plants were therefore overstated .3 cents per hundredweight as a result of profits on hauling. On the other hand, plants with lower prices had losses on hauling and were therefore subsidizing hauling. As a result, reported prices by these plants were an average of 2.3 cents per hundredweight lower than actual prices paid.

Patronage Refunds.—Cooperatives (which comprised 45 of the 52 plants) often allocate profits to producers at the end of the fiscal period in the form of patronage refunds. If, as claimed in principles of cooperation, they are additional payments for doing business, reported prices for milk will be understated.

The average cash dividend for all plants was 2.1 cents per hundredweight. On the average, then, plants understated prices by 2.1 cents per hundredweight as a result of patronage dividend policy.

The lowest pay price group in the two states paid the largest cash and total dividends per hundredweight—3.7 and 9.6 cents, respectively. This was more than one cent per hundredweight above the high price group. Thus, low paying plants understated prices more through patronage refunds than did high paying plants.

Thus, the net effect of the three factors on reported milk pay prices for the Minnesota and Wisconsin manufacturing grade milk plants was: butterfat test error, +4.1 cents per hundredweight; hauling subsidy, −1.4 cents per hundredweight; and cash dividends, −2.1 cents per hundredweight; net overall effect, +.6 cents per hundredweight.

On the average, then, prices reported paid by these 52 plants exceeded actual prices paid by .6 cents per hundredweight. Reported prices are therefore quite similar to actual prices when the effect of hauling subsidies and patronage refunds are balanced against butterfat test error. Hence, it can be concluded the Minnesota-Wisconsin series prices are quite similar to the actual prices paid.

Relationship Between Operating Variables for Milk Plants and Farm Milk Prices Paid by Plants

The relationship between the level of pay prices and characteristics of the firm and the market was analyzed by two methods—classification of various operating variables by level of pay prices and stepwise regression analysis.

The classification procedure indicated that several factors were related to level of pay price: cash dividends, percent of income from a given manufactured product, depreciation allowance per hundredweight of milk, equity ratios, current ratios, plant location, costs of processing, and seasonal variations in milk supplies. Multiple regression analysis indicated that percent of income from butter and powder, plant locations (from Chicago), and gain or loss on milk hauling, were significantly related to the level of pay prices.

Thus, although there is some relationship between plant operational procedures and the level of farm milk prices paid, use of competitive pay price series based on average prices paid by all plants would not necessarily be inequitable with respect to plant price obligations for milk used in either Class I (fluid) or Class II (manufactured products). Many operational and marketing factors affect the price a plant can afford to pay for milk, and some are offsetting. Others can be adjusted or nullified by specific operational or marketing action. The use of competitive pay price series in federal milk order pricing, therefore, is not in itself inappropriate on the basis that many plants cannot afford to pay these prices. Instead, use of competitive price series provides an incentive for plant management to make adjustments in operations that will allow it to pay the highest possible producer prices—an important outcome in itself.

Policy Implications

Although the analysis indicated that reported manufacturing grade milk prices are quite similar to actual prices, some differences do exist, particularly with respect to the effect of butterfat test error. More accuracy in reported prices could result in more accuracy in competitive pay price series and hence greater equity when these price series are used in federal milk order pricing. The following recommendations are advanced in the interest of greater accuracy:

1. More detail could be reported for price series that are used for various regulatory programs. Average hauling subsidies, separate can and bulk milk prices, some estimate of average cash patronage refunds, and average butterfat differentials would be useful. With respect to refunds, some average of refunds for the previous years could be applied to the series to adjust it to a competitive level. The same procedure might be recommended for hauling losses or gains. However, measurement of this component would be more difficult.

2. Separate butter-powder and cheese series could be reported for the Minnesota-Wisconsin plants. This would provide relief for plants that have difficulty changing from one product to another. In addition this would overcome the objection that regulated federal order handlers are

required to pay more for milk used in some manufactured dairly products than non-federal order manufacturing plants pay for milk in the same products.

3. Additional resources could be devoted to regulation of milk testing, weighting, and reporting to assure accurate reporting of milk prices and payment of these prices to producers. This may involve additional surveillance of plant operations and more frequent checking of equipment and methods. Research on testing procedures, changes in product yields and expected variation in yields are also needed. It is possible that a federal order for manufacturing grade milk could overcome many of the problems of inaccurate butterfat tests and weights.

We are working through our public policy programs to incorporate the results of this applied research into federal milk order pricing procedures, and to improve the accuracy and reliability of prices reported by dairy plants for use in price series. We feel this application of research results through public policy programs, will be of value to the dairy industry in insuring more reliable, accurate, and equitable milk price series. This in turn will result in greater stability and equity in milk prices generally, in price series, and in federal milk order prices.

The Pure Theory of Government Aid to Agriculture

MICHA GISSER

THE main goal of agricultural policies of developed countries is to alleviate poverty on farms. The programs usually considered by governments to achieve this goal are (a) price-support, which can be described as shifting the demand for farm output outward; (b) acreage control; (c) subsidizing inputs; and (d) production controls. In order to examine the effectiveness of these aid programs, a model of the farm labor market is constructed.[1] Available econometric estimates for the United States are utilized by the model.

The Model

The model is based on the usual assumptions of aggregation [1, 3, and 4]. All variables are expressed in logarithms throughout the analysis. The unadjusted demand and supply functions for labor are:

$$W_d = a_1 + a_2L + a_3C \tag{1}$$

$$W_s = \bar{b}_1 + b_2L \tag{2}$$

where W, L, and C denote the farm wage rate, farm labor force, and capital, which includes land.

The vertical shift in the supply of labor is reflected in $\bar{b}_1$, Replacing $\bar{b}_1$ by $-b_2b_1$, where b_1 reflects the horizontal shift in the supply of labor, and solving for W and L, we obtain the following reduced forms:

$$W = \frac{a_1b_2}{d} + \frac{a_2b_2}{d}b_1 + \frac{b_2a_3}{d}C \tag{3}$$

$$L = \frac{a_1}{d} + \frac{b_2}{d}b_1 + \frac{a_3}{d}C \tag{4}$$

where $d = b_2 - a_2$.

Adjusting equations (3) and (4) for the assumption that the farm wage rate is equal to the marginal physical product of farm labor multiplied by the price of agricultural output, and introducing the following equations (in logarithms):

(5) Production function: $Q = k + (1 + a_2)L + a_3C$

(6) Demand for labor: $W_d = k + (1 + a_2) + a_2L + a_3C$

(7) Value marginal product: $W_d^* = W_d + P$

---

[1] Part of this model was developed in another article [3].

MICHA GISSER *is associate professor of economics at the University of New Mexico.*

and

$$\text{(8)}\quad \text{Demand for final output:}\quad P = \frac{1}{\eta}Q - \frac{H}{\eta}$$

we obtain a complete model, where Q, k, W^*, P, and η denote agricultural output, the neutral shift in the production function, value marginal product of farm labor, the price of final output and price elasticity of final farm output, H, which will play a role later, is the horizontal shift in the demand for output.

By substituting the right side of (6) for W_d in (7), the right side of (5) for Q in (8), and the right side of (8) for P in (7), we obtain the *adjusted* form of a demand function for labor:

$$\text{(9)}\quad \begin{aligned} W_d^* = 1 + a_2 - \frac{H}{\eta} + \left(1 + \frac{1}{\eta}\right)k + \left[a_2\left(1 + \frac{1}{\eta}\right) + \frac{1}{\eta}\right]L \\ + a_3\left(1 + \frac{1}{\eta}\right)C \end{aligned}$$

Substituting the intercept and the coefficients of L and C in (9) for a_1, a_2, and a_3, respectively, in (3) and (4), we obtain:

$$\text{(10)}\quad \begin{aligned} W = M - \frac{b_2}{\eta\cdot D}H + \frac{\left[a_2\left(1 + \frac{1}{\eta}\right) + \frac{1}{\eta}\right]b_2}{D}b_1 \\ + \frac{b_2 a_3\left(1 + \frac{1}{\eta}\right)}{D}C \end{aligned}$$

$$\text{(11)}\quad L = N - \frac{1}{\eta\cdot D}H + \frac{b_2}{D}b_1 + \frac{a_3\left(1 + \frac{1}{\eta}\right)}{D}\cdot C$$

where

$$D = b_2 - \left[a_2\left(1 + \frac{1}{\eta}\right) + \frac{1}{\eta}\right]$$

and M and N are constants.

Note that capital and land are treated by the model as exogenous factors. Since land is a fixed input, and since the process of capital formation on farms is relatively slow, such a treatment is justified in the short run.

In order to estimate the value of the coefficients appearing in equations (10) and (11), use is made of available econometric estimates that have received substantial acceptance in the agricultural economics literature [1, 2, 4, 5, and 6].

The values of the econometric estimates are

Parameter		Econometric estimate
Price elasticity of demand for farm output (η)		−0.25
Coefficient of labor in the production function ($1+a_2$)		0.50
Coefficient of capital (a_3):	Total capital	0.30
	Land	0.15
Reciprocal of supply elasticity of farm labor (b_2)		0.30, 1.00

The estimated values of the coefficients in equations (10) and (11) are shown in Table 1.

Table 1. Estimated values of coefficients in equations (10) and (11)

The Value of b_2 (Reciprocal of supply elasticity of labor)	Coefficients of			
	H A shift in demand for farm output	b_1 A shift in supply of farm labor	*C*	
			Farm capital including land	Farm land
	Farm wage equation (10)			
0.3	0.43	−0.27	−0.10	−0.05
1.0	1.14	−0.71	−0.26	−0.13
	Farm labor equation (11)			
0.3	1.43	0.11	−0.32	−0.16
1.0	1.14	0.29	−0.26	−0.13

Price Support

The price support program in the United States can be technically summarized as a 5 percent horizontal shift to the right in the demand for farm output. Assuming an elastic supply curve of farm labor ($b_2=0.3$), as indicated by Table 1, the effect of the price support program is to raise farm wages by about 2 percent, and increase farm employment by about 7 percent. For a less elastic supply curve of farm labor ($b_2=1.0$) the results are 6 and 6 percent, respectively. Thus, the costly price support program raises farm wages by a percentage which is somewhere between 2 and 6 percent. Regardless of the assumed supply-of-labor elasticity, it increases farm employment by 6–7 percent. Notice that the effect of the price support program on farm wages and employment is once and for all.

Acreage Control

Acreage control is the least effective among government aid programs. The coefficients of land in Table 1 are −0.05 and −0.13 in the farm wage equation, and −0.16 and −0.13 in the farm labor equation. Accordingly, an acreage control program is practically ineffective. A 10 percent reduction in land use would lead to somewhere between 0.5 to 1.3 percent increase in farm wages, and 1.3 to 1.6 increase in farm employment.

Subsidizing Inputs

The desirable effect of price support is a rise in the farm wage rate. The program is very costly, and its by-product, i.e., a higher employment level on farms is undesirable. The effects of acreage controls are similar in direction to that of price support; A rise in the wage rate coupled with a higher level of farm employment. Quantitatively the effects of acreage control are negligible.

Subsidizing capital inputs would lead farmers to use more capital in the long run. The coefficient of capital are negative and relatively small. They are estimated at -0.10 and -0.25 in the farm wage equation, and -0.32 and -0.26 in the farm labor equation. Accordingly, subsidizing capital inputs would give rise to two effects working in opposite direction than the programs mentioned above: Farm wage rate would further deteriorate, and farm employment would decrease. In this case, the first effect is undesirable, but the second effect is desirable.

Production Controls

In order to analyze production controls, the model has to be simplified. Recall again that all variables are expressed in logarithms. The derivative of the production function (5) with respect to labor can be written as

$$W_d = (1 + a_2) + Q - L \tag{12}$$

Equation (12) replaces equation (6) in the model. The demand for labor equation (12), together with equations (7) and (8) yield

$$W_d^* = 1 + a_2 - \frac{H}{\eta} - L + \left(1 + \frac{1}{\eta}\right)Q \tag{13}$$

The revised demand for labor equation (13) together with the supply equation of labor (2) yield the following reduced forms:

$$W = F + \frac{b_2\left(1 - \frac{1}{\eta}\right)}{1 + b_2} Q \tag{14}$$

$$L = G + \frac{1 + \frac{1}{\eta}}{1 + b_2} Q \tag{15}$$

where F and G are constants.

For a relatively elastic supply of labor ($b_2=0.3$), the coefficients of output are -0.7 in equation (14) and -2.3 in equation (15). Thus, if production controls leading to 10 percent reduction in farm output could have been effectively enforced, farm wages would have risen 7 percent and farm employment would have increased 23 percent. While a 7 percent increase in farm wages is welcome, a 23 percent increase in farm employment is a disaster. The percentage changes for low supply elasticity ($b_2=1.0$) are 15 and 15 percent, respectively.

Summary and Conclusions

The price support program is costly and somewhat effective only when low supply of labor elasticities are assumed. The acreage control program is practically ineffective. Subsidizing farm inputs leads to further deterioration of farm wages. However, unlike the two other programs, this program induces more farm out migration. Production controls can lead to desirable improvements in farm wages, but it affects adversely the process of farm outmigration, especially when high supply of labor elasticities are assumed.

The effects of each of the above programs are once and for all. A rightward shift in the supply of farm labor would cause the favorable effect of any of the above programs to dissipate over a short time period. This is indicated by the fact that the coefficients of b_1 (horizontal supply of labor shift) in the farm wage equation are negative. [3]. Notice, in Table 1, that the only variable that has the right sign needed for alleviating poverty on farms and at the same time inducing more farm outmigration is b_1. Hence, the best way to attack the farm problem is to induce a leftward shift in the supply of farm labor.

Effects of Public Programs for Outdoor Recreation on Personal Income Distribution

LEONARD A. SHABMAN AND ROBERT J. KALTER

IN view of the multidimensional nature of the social welfare function, concern for the economically efficient provision of public goods and services should be coupled with equal concern for the equity effects of that provision [4]. More specifically, the personal income distribution effects of a project or program, as well as other equity considerations, must be analyzed if the planning process is to provide the information flows necessary for making public decisions consistent with the general welfare. Quantification of such effects make the trade-offs that exist between governmental objectives more explicit and point up the equity impact of programs undertaken wholly or partially for other reasons.

The Study

This paper reports on portions of an empirical study carried out with the use of fiscal 1968 data on New York State administered outdoor recreation expenditures[1]. Several different conceptual approaches were used and compared. The first utilizes a classical flow of funds form of analysis, tracing the redistribution effects of all state revenue devoted to outdoor recreation in a given year. In this approach, recreation expenditures were treated as gross transfer payments and, for each income class, were netted against tax and fee burdens imposed. The second approach analyzes the present value equity impact of incremental state investment in recreation facilities. Projected annual benefits, measured by a proxy for willingness to pay and converted to a present value basis, were used to estimate gross equity impacts and, for each income class, were netted against discounted costs.

Empirical considerations dictated that the income base used be household income before taxes, as defined for the National Recreation Surveys (NRS) [2, 3], and that the class definitions be: under \$3,000; \$3,000-5,999; \$6,000-9,999; \$10,000-14,999; \$15,000 and over. The distribution of households within these classes was taken from the Current Population Survey.

Data from the NRS were used to estimate the proportion of user days consumed by each income class for any given activity. These proportions, when multiplied by the total dollars spent by the state on that activity or

---

LEONARD A. SHABMAN *is a graduate research assistant and* ROBERT J. KALTER *is assistant professor of resource economics at Cornell University.*

by gross benefits, gave the amount of transfers and benefits, respectively, accruing to any one class. Summation of these flows over all activities gave gross transfers and benefits to each class. Columns 1 and 3 in Table 1 give the results of these calculations.

To determine net impacts, a measure of burden was needed. All state administered funds are raised through taxes and fees of various kinds. The amounts these separate revenue sources contributed to recreation was determined from available New York State budget data. Then, burden, as defined for the two approaches, was allocated for each revenue source to the income classes. For the net transfer payment approach, all state administered money spent for recreation in fiscal 1968 appeared on the cost side. For the net benefit approach, only capital investment and projected annual operating costs were allocated by class. In both cases, the allocation process was the same.

After allowance for shifting, the incidence of the tax by income class was determined from household possession, use, or purchase of the item on which the tax or fee was imposed. For example, tobacco consumption by income class served to indicate the proportion of the cigarette tax borne by each income class. This process was used for all the burdens that fell on individual households. Household purchases and use of products and services by class were taken from a recent Bureau of Labor Statistics survey and the *Survey of Consumer Finances.* The unshifted burden of the corporate income tax was assumed to fall in proportion to individual dividend income by class. Dividend income by class was taken from the Internal Revenue Service's *Statistics of Income 1966.* Summing all of the individual burdens over each class gave the total burden of taxes and fees.

Subtraction of burden from gross transfer payments gave the net transfer payment effect for fiscal 1968. The net benefit approach considers impact over time. In this case, costs and benefits to each class were discounted to present value and netted out. The procedure may be summarized:

$$W_j = \left[\sum_{t=1}^{T} \frac{B_j}{(1+i)^t} \right] - \left[\sum_{t=1}^{T} \frac{C_j}{(1+i)^t} + K_j \right]$$

where: W_j equals net present value benefits accruing to income class j; i equals the discount rate; T equals the time horizon; B_j equals the estimated annual benefits accruing to income class j; C_j equals estimated annual operating costs imposed on income class j; K_j equals capital costs imposed on income class j.

Columns 2 and 4 in Table 1 give the results of these calculations.

Table 1. Equity effects of New York State administered outdoor recreation expenditures

Income class / Form of analysis	Flow of funds[a]		Present value[b]	
	Gross transfers (1)	Net transfers[c] (2)	Gross benefits (3)	Net benefits (4)
	thousand dollars			
Under $3,000	9,255	5,543	13,071	10,368
$3,000–5,999	18,837	6,797	25,633	17,267
$6,000–9,999	23,930	2,836	32,189	17,614
$10,000–14,999	11,933	−4,257	23,277	12,207
$15,000 and over	15,045	−10,956	13,699	−3,462

[a] On a per household basis, gross transfers were $9.72, $15.27, $14.00, $10.29, and $22.04; net transfers were $5.82, $5.51, $1.66, −$3.67, and −$16.05.

[b] Based upon a 25-year time horizon, 4–5/8% discount rate, $1.50 per visitor day as a proxy for willingness to pay, and proportional income classes over the time horizon. Not given on a per household basis because the absolute number of households in each class will vary over the time horizon.

[c] Summation does not add to zero because of rounding.

Conclusions

The flow of funds analysis revealed that the New York State outdoor recreation program does have an annual redistribution effect. The two upper income groups realized negative net transfer impacts, while the lower three groups obtained positive net transfers. The income brackets under $6,000 received over 80 percent of the total positive impact. The flow of funds approach, however, has the weakness of only examining the equity impacts of total expenditures for one time period, even though the capital investment portion of those expenditures could result in equity changes over a longer time horizon. Thus, when undertaking the economic analysis of investment portions of a program, the present value method would appear to be more appropriate

Using this approach, the analysis showed that the upper income group realizes negative net benefits while the four lower classes realize positive net benefits. However, positive net benefits are the smallest for the lower class and largest for the three middle income groups. Over 80 percent of positive net benefits accrue to the $3,000-14,999 brackets.

Thus, given the program being analyzed, ignoring considerations of quality, and assuming that per unit benefit values do not vary across classes, both approaches indicate that the lower and middle income groups receive positive equity impacts. However, abstracting from repayment principles, a different result emerges. The lowest income class does not utilize state provided recreation facilities to the extent of other classes on either an absolute or per household basis, and this is reflected in the values displayed in columns 1 and 3 of Table 1. Given the value judgment that state provided recreation services should be available to all income groups on an equal opportunity basis, this would appear to indicate that the lower income class, largely urban in New York State, either doesn't care to participate or lacks the opportunity for participation because of the inability to pay transportation costs and/or purchase equipment associated with recreation participation.

Government Payments and the Distribution of Income in Agriculture

RAYMOND M. LEUTHOLD

FARM programs in the United States have long had the improvement of farm income as their professed goal. Explicit or implied in this goal has been the desire to adopt those farm policies that improve the income of low income farmers. In fact, Congress and farm organizations continue to use this justification for our farm legislation. However, recent publicity about extremely large payments to some producers and very small payments to others has caused many to question whether our farm programs have been an effective means of maintaining minimum farm income standards. It is the purpose of this paper to analyze the distributive effects of our agricultural programs and examine whether government payments have increased or reduced the inequality in the distribution of income in agriculture over the past few years.[1]

Analysis

In order to determine the effects of government payments on the distribution of income in agriculture, this study utilizes the conventional Lorenz curve analysis and the resulting Gini concentration ratio. The Lorenz curve plots the cumulative percent of farm income against the cumulative percent of farms receiving that income. The Gini ratio, and quantitative measure of inequality, is defined as the proportion of the area between the diagonal line of perfect equality and the Lorenz curve to the total area under the diagonal. The ratio lies between 0 (complete equality of distribution) and 1 (maximum concentration).

In computing the Gini ratios, farms were divided into six economic size classes according to the value of gross sales as reported in the *Farm Income Situation* [7]. Plotted against this was realized net farm income.[2] It is recognized that, if total money income were used or if unrealized income were included, the ratios would probably be of different magnitude from those resulting when realized net income is used. However, the important implication for this paper is not the size of the ratios but how the ratios change over time.

Table 1 shows the Gini ratios for the years 1959 through 1967 for realized net farm income. The general trend over this nine-year period was to-

---

[1] There seems little doubt that farmers would probably have lower incomes in the absence of farm programs, but that is a separate question and not analyzed here.

[2] Realized net farm income includes government payments.

RAYMOND M. LEUTHOLD *is assistant professor of agricultural economics at the University of Illinois.*

Table 1. Gini concentration ratios of realized net farm income and government farm payments, 1959–1967

Year	Gini ratio	
	Realized net farm income	Government payments
1959	.484	.466
1960	.499	.474
1961	.513	.485
1962	.500	.494
1963	.531	.504
1964	.568	.506
1965	.548	.518
1966	.557	—
1967	.542	—

Source: [6, 7].

ward increasing inequality, but the increase was not steady. The largest ratio occurred in 1964. This trend can be compared with the Gini concentration ratios for total money income for select farm groups, which showed a general decline with large fluctuations over the years 1948–1959 [2].

What role have government payments played in this distribution pattern? The Gini concentration ratios of government payments for the same economic farm size classes were computed for 1959-1965 and are also shown in Table 1.[3] Government payments in this case include primarily price-support programs, allotment and land-retirement programs, and direct-payment programs.

A steady increase occurs in the government payments concentration ratios over the seven-year period, reflecting increased concentration of payments among large farmers. One might initially compare these coefficients with the corresponding coefficients for realized net farm income and conclude that, since the government payment ratios are always smaller, government payments decrease the disparity in the distribution of income during any one year. A similar relationship is also noted in the report of the Food and Fiber Commission [6, p. 191]. However, this comparison ignores the question of the effect of government payments on the distribution of farm income over time.

To answer this question, a simple regression relating the realized net income Gini ratio to the government payment Gini ratio was computed for the period 1959 to 1965. The results are as follows:

$$(\text{Net Income}) = -.154 + \underset{(3.58)}{1.37}\,(\text{Government Payments})$$

$$R^2 = .72 \qquad D.W. = 2.38$$

where the number in parenthesis is the t-ratio.

---

[3] Data on an aggregate level are not readily available for 1966 and 1967.

This simple model indicates that 72 percent of the variation in the realized net farm income concentration ratios can be explained by the variation in the government payment ratios. That is, the concentration of net farm income is sensitive to the distribution of government payments. The general conclusion that farm programs worsen the existing distribution of income in agriculture has been implied before by Bonnen [1], Coffey [3], Herendeen [4], and McKee and Day [5]. However, none of these studies has explicitly tested the relationship between the concentration of net income and the concentration of government payments over several consecutive years.

The farm programs that were the largest and showed the greatest increase during this seven-year period were the Wheat Program and Feed Grain Program. In 1965 these two programs accounted for 78 percent of the government payments. Both Bonnen [1] and McKee and Day [5], in analyzing individual programs, concluded that wheat and feed grain payments are highly concentrated and that present policy trends probably do not reduce the inequality in income. Also, from 1959 to 1965 the payments under the Sugar Act increased, and Bonnen showed that the Gini concentration ratio for sugar cane payments in the United States is 0.8.

If data were available, it would be interesting to include the concentration ratios of government payments for 1966 and 1967. It appears that these ratios would probably be even larger, since payments under the Cotton Program increased over 1000 percent since 1965. Most of our very large farm payments, $50,000 and greater, go to cotton producers. Bonnen concludes that cotton payments are very highly concentrated and that the ratios increased from 1961 to 1964 [1].

Conclusions

In general, as government payments under U.S. farm programs become more highly concentrated over time, realized net farm income also becomes more highly concentrated. This is understandable, since the size of government payments is based on the amount of land or volume of output a farmer has; the small farmer has little of either upon which he can claim government subsidies. Nevertheless, the increasing concentration ratios indicate that the farm programs are inefficient instruments in helping the poor farmer break the poverty cycle. If the goal of our farm programs is to aid the poor farmer, we should give serious thought to redesigning the agriculture payment plans.

The recent proposal in Congress to limit the size of government payments to any one farm to $20,000 would reduce the disparity in farm income distribution but would not help the impoverished. Such adjustments in our present programs will affect only the recipients of these payments, the large commercial farmers, and will have little impact upon the poor if the money saved is taken out of agriculture. If we place priority on aiding the low income farmer, there are several program proposals available to handle this, for example, the negative income tax and family allowances. If it is also our desire to subsidize commercial agriculture because it is a critical industry and because of the high risks in farming, a more equitable approach may be through the Federal income tax system. Nevertheless, Congress, commercial farm organizations, and our policy makers should reevaluate our priorities in agriculture and consider new programs designed specifically to meet these priorities.

Long-Term Versus Short-Term Land Retirement

A. Barry Carr

SINCE funds to control farm production and maintain prices are not unlimited, agricultural programs should be selected from among those that use Government funds most efficiently. The purpose of this paper is to evaluate the relative efficiency of annual versus long-term land retirement programs in removing the most production per dollar of Treasury cost.

To determine the theoretical efficiency of agricultural programs, we assume that a farmer is willing to divert his land or allotment whenever the Goverment payment equals or exceeds the difference between gross receipts and variable costs. Thus, the ratio of variable costs to gross returns is correlated with the amount of production removed per dollar of payment. Programs that are associated with a high variable cost will give a higher efficiency. Efficiency increases as the time period of the program is extended and more the the farmers' costs become variable. Hence, the greater theoretical efficiency of long-term retirement over a yearly diversion program.

Often a discrepancy is observed between the theoretically computed payment that would induce program participation and the amount that farmers state would actually be required. In some cases, farmers may require more than the theoretically computed payment to divert their land from production. This payment premium may be greatest for long-term programs. Farmers tend to shy away from long-term contracts because of their inflexibility over time. Short-term diversion, which is favored by more farmers, has a lower variable cost situation and a smaller theoretical efficiency.

The gap between the theoretical payment and the payment asked by farmers for participation was gauged by data from a survey of 198 Oklahoma dryland farmers eligible for the wheat and/or feed grain programs. The sample was distributed proportionately over four randomly selected countries—one country from each of the four major agricultural areas of western Oklahoma. Within each county, names of owner-operators and operators were randomly drawn from the ASCS county records.

The cropland available was divided by the farmer into three quality categories. The variable cost of producing wheat and grain sorghum and

---

A. Barry Carr *is an agricultural economist with the Farm Production Economics Division, Economics Research Service, USDA, stationed at Oklahoma State University.*

the yields associated with each land category were also estimated by the farmer. Because the available allotments and bases are less than the total cropland on each farm, certain assumptions are necessary to lend consistency to the analysis. Some of these farms also had a cotton allotment. It will be assumed that the maximum permitted cotton will be grown on the best land. Wheat and grain sorghum will have second and third priorities respectively on the best land. There is sufficient of the best and average land to grow the entire wheat allotment. All grain sorghum would be grown on average quality land. Diverted or idle land, hay, pasture, and noncontrolled crops have a residual claim on the lower quality land categories. A breakdown of acreages, yields, and costs are given in Table 1.

The theoretical payment required to obtain participation in a retirement program was assumed earlier to be the difference between gross receipts and variable costs. Table 2 gives the theoretical payments for a one-year diversion when wheat is supported at $2 per bushel and grain sorghum at $2 per hundredweight. A theoretical payment could not be computed for five-year and ten-year programs because of a lack of variable costs data for these time periods. But assuming no changes in yields

Table 1. Descriptive parameters of farm sample

Item	County			
	Grant	Harper	Tillman	Texas
Farms (number)	73	33	47	45
Cropland (acres)	399	653	420	650
1967 cotton allotment (acres)	0	0	65	0
1967 wheat allotment (acres)	279	430	221	390
1967 feed grain base (acres)	29	87	28	110
1967 ASCS project wheat yield (bushels)	27.6	16.3	28.1	17.4
1967 ASCS project sorghum yield (bushels)	31.7	25.8	38.6	35.0
Best quality cropland (acres)	210	295	175	181
Cotton (acres)	0	0	52	0
Wheat (acres)	210	295	123	181
Wheat yield (bushels)	32.4	21.5	29.4	17.6
Wheat variable cost[a] (dollars per acre)	17.03	9.74	17.34	9.79
Average quality cropland (acres)	131	261	157	349
Wheat (acres)	69	135	98	209
Wheat yield (bushels)	24.9	15.6	24.7	14.7
Wheat variable cost[a] (dollars per acre)	17.33	9.64	17.72	9.94
Grain sorghum (acres)	29	87	28	110
Sorghum yield (bushels)	29.7	19.8	37.5	26.8
Sorghum variable cost[a] (dollars per acre)	16.00	9.33	15.00	9.28

[a] Variable costs include seed, fertilizer, hired labor, chemicals, machinery repairs, and fuel, custom harvesting, and hauling. Excluded from production costs are the operator labor, unpaid family labor, and land costs.

Table 2. **Comparison of theoretical payments and average payments required by farmers to retire entire wheat allotment or grain sorghum base over three time periods**

Item	County			
	Grant	Harper	Tillman	Texas
	dollars per acre			
Wheat allotment:				
Theoretical 1-year	43.99	29.59	37.11	22.22
Farmers' asking rates				
1-year	39.72	23.02[a]	32.89[a]	22.06
5-year	41.29	19.93	28.25	21.04
10-year	42.00	17.92[a]	29.04[a]	21.16
Grain sorghum base:				
Theoretical 1-year	17.26	12.85	27.00	20.74
Farmers' asking rates				
1-year	35.02	16.80	22.72	24.05[a]
5-year	32.76	17.33	24.07	21.28
10-year	33.65	17.33	24.64	21.11[a]

[a] The 1-year and 10-year mean payments are significantly different at the 5 percent level when tested with the "*t*" test procedure adjusted for unpaired observations and unequal variances.

and prices, the longer run theoretical payments would be lower than the value given for one year.

Each farmer was asked what payment he would require to divert entirely to wheat allotment or grain sorghum base for one year. He was also asked what payment he would need to retire his allotment or base for a five-year and ten-year period. In addition to not producing the crop, he would be required to divert to a soil conserving use an equivalent acreage of cropland. Table 2 shows the payment rates per acre reported by farmers in each county. It must be recognized that the estimates given by farmers in this study may not accurately correspond with their actions if they were making a decision in an actual program situation.

Because of the effects on cost of production, long-run retirement programs were hypothesized to be less expensive and, hence, more efficient in use of Government funds. The most significant reduction in payments that farmers said they would accept when changing from annual to long-term retirement was for wheat allotments in Harper County. Smaller but still significant reductions occurred for wheat allotments in Tillman County and grain sorghum bases in Texas County. None of the other differences in the average payments required was statistically significant.

A comparison of the one-year and ten-year program costs, based on farmers' asking rates, for the total wheat and grain sorghum acreage on all farms in the study shows a slight efficiency advantage for the long-term program. To retire the entire wheat allotment on all 198 farms in the four counties for one year would cost $1,864,411. If the same allotments were retired for a ten-year period, the annual cost would be $81,716 less, a reduction 4.4 percent. Retiring all of the grain sorghum bases for one year would cost $271,318. The annual cost of the ten-year program would be $13,407 less, or 4.9 percent.

It might be expected that the farmer's long-run price expectations would affect the term structure of his required retirement payments. The data showed no such correlation. Harper County had the highest five-year wheat price expectation, $2.03 per bushel; yet it showed the largest reduction in diversion payment required over time. Grant County farmers anticipated in five years a price of only $1.72 per bushel; yet they would require a higher payment rate for the long-run program than for one-year retirement.

The relationship between the theoretical payment and the farmers' asking payment for a one-year program is interesting. Wheat usually is the cash crop. Apparently, farmers were willing to accept a lower return to avoid the associated risks. They were willing to accept a lower retirement payment because it was sure. Grain sorghum usually is fed or grazed on the farm rather than sold. If this base were to be retired, farmers would have to make costly adjustments in their livestock programs. They may impute a higher return to grain sorghum fed through livestock than would be obtainable on a cash market. This would probably explain why farmers in this area often require a higher payment for diverting sorghum than might otherwise be expected.

Based on conditions in Oklahoma, these data seem to justify the use of long-term allotment and base retirement programs where they are accepted by farmers. Maximum efficiency in the use of Government funds would likely be achieved where farmers have been given the choice of one, five, or ten-year programs on a sealed bid basis. Bids would be accepted first where the most production would be removed per dollar of payment. Individual farmers could vote their time preference through their bids. The Government could discriminate between bids so as to minimize the cost of a specified reduction in output.

TOOLS OF OUR TRADE: FARM MANAGEMENT

CHAIRMAN: RAY BILLINGSLEY, TEXAS A&M UNIVERSITY

Returns to Farm Resources

DON BOSTWICK

IT seems to me that there are three basic questions suggested by this topic:

Can returns to farm production resources be isolated?
Can they be quantified?
Does it matter?

I could establish a new record for brevity by answering "yes" to all three of these questions and then sitting down. But this would require more discipline than I possess and would not be very convincing either. So I shall use my twenty minutes to outline the supporting arguments to my three positive answers.

Can Returns Be Isolated?

Resources are *goods* when they are of the stock kind and *services* when they are attributes that flow from goods. Farm production resources may be classified into physical, human, and financial resource sets. The set of physical resources includes those members that are physical and nonhuman, and that are used in the production process. Examples are land, machinery, livestock, fertilizer, fences, and stock water ponds.

The set of human resources includes those attributes of people that are used in the production process. Examples are labor, skills used in the management of production resources, and those of the entrepreneur who arranges the availability of resources for production.

The resources included in the physical and human sets may be subjected to value transforms and then become members of the set of financial resources, which also includes such members as cash money and other certificates of value.

In financial management research, the resources used in farm production are viewed as serving the five distinct functions of investment, ownership, labor, management, and entrepreneurship. It is the primary task of this paper to establish the system by which all returns to farm production may be allocated among these five functions.

DON BOSTICK *is an agricultural economist with the Farm Production Economics Division, Economic Research Service, USDA.*

Investment

Money is the index by which value transforms are applied to otherwise disparate resources, such as bushels of seed, tractor-hours, and dollars of investment. But money is indifferent to the source of its control and to the kind of exchange it serves. Money is not self-allocating, it does not automatically exchange itself for that resource having the highest marginal return in production. Financial decisions are made by people, and the ex-post facto results of the decisions cannot be blamed on the money used in an exchange.

Investment is a process of exchanging a quantity of money for a promise of a greater quantity in return. Interest is the difference between the quantity exchanged and the quantity eventually paid back. An investment is uniquely defined by the quantity of money exchanged and by the conditions attached to the exchange contract. Since money is indifferent to its exchange conditions, any given dollar cannot have a higher return for one user than for another in the same use. To assume that a dollar in one checking account is in any way more or less valuable than a dollar in any other checking account is to open the door to conceptual anarchy in economic analysis—or to belief in magic.

An investment returns to the investor exactly that rate fixed by the contractural agreement governing the investment. The return to an endogenous investment is presumed to be the same as the rate that would have been paid for the same investment had exogenous money been exchanged. A farmer who uses exogenous investments in his production pays a return defined by contract. A farmer who uses endogenous money has an investment return defined by the market rate that he might have paid for the same investment in the marketplace.

Ownership

While investment is an economic activity of people, ownership is a legal condition with economic consequences. The owner of a resource performs the function of holding the legal right to its use and disposition. There is often, but not always, an investment required as a condition to the enjoyment of ownership.

Just as money is indifferent to the source of its control and to its use, so are the owned physical resources (goods) indifferent to their owner and to his use of them. The use decision is made by the person exercising the ownership function or by someone who has rented the use-right from the owner. Ownership returns are given by the market rate at which use-rights may be rented from the owner.

Net rent is the gross rent, as defined in the rental market, less such ownership costs as taxes, insurance, and maintenance, plus or minus changes in book value. Changes in book value may be negative for depreciable resources and for those that suffer obsolescence and destruction in use. Positive changes in book value might occur with goods that grow over time, such as replacement heifers and crops or land held by owners on an upward-trending market.

Labor

Labor is a somewhat peculiar resource in that one may contract a use-right to labor but may not own the person who provides the labor (slavery having been abolished). The labor function is provided by people, while machines provide work. There are markets in which the various qualities and kinds of labor have established exchange values. The return to exogenous (hired) labor is given by contractual agreement, while that for endogenous labor must be estimated by the appropriate market rate.

Management

It is the function of management to direct and control resources in the production process. The returns to the management function are given by the established market, but this return is not always easy to obtain. The market for managerial services in agriculture is less well developed than the markets for labor, ownership, and investment. Additionally, management is often paid a salary plus some percentage of the gross business. The gross is known only after the management function has been performed and can therefore only be some probability estimate ex ante. As long as the research problem is one of allocating returns ex post of the production process, there is no particular problem in valuing the management function. If the problem is to estimate returns ex ante of production, the management return must be expectational rather than contractually certain.

Entrepreneurship

The entrepreneur organizes and makes available the goods and services used in production. He takes the risk of allocating resources at more than their market price and of allocating them to purposes that are less than optimal. He also gets the financial rewards of making resources available at less than their market price and of allocating them at the economic margin. Entrepreneurship is the residual claimant to the financial returns generated by the farm production process. The return to entrepreneurship may be positive or negative in any given production cycle and may vary widely over several production cycles if there are significant stochastic elements in the production and resource pricing system.

The entrepreneurial return may be equated with the classical category of economic rent. If all factor and product markets are perfect, the entrepreneurial returns are a reasonable indicator of the extent to which the real world departs from the classical economic model.

In theory, each function can be provided by separate entities, in which case the entrepreneur would be the entity we usually label "the farmer," while the investment, ownership, labor, and management functions would all be hired exogenously. In theory, all five functions can be endogenous to a single farm firm. This is the paragon that we so often find in the currently received theory of the firm. The system of functional returns sketched here allows the researcher to calculate precise returns to all resources over the continuum between these two extremes.

Can Returns Be Quantified?

To deal with the question of quantification of returns to farm production resources, I have drawn on some published per-acre data that applied to the years 1965 and 1966 (see Appendix). Please do not quarrel over these numbers—I use them only as the stuff of an illustration. I have constructed three cases from the Illinois data to represent both extremes and a middle-point of the farm resource control continuum. The quantity of total resources allocated is the same in each case. Therefore, any difference in returns must be due to the way that resources are controlled.

Case 1: 100 percent investor

The operator owns all of the physical resources used on his corn farm, supplies all of his own labor, uses no risk investment from exogenous sources, and supplies all of the management. There are no exogenous returns because there are no exogenous resources supplied. The calculation of returns is summarized in the first column of Table 1.

Case 2: Pure renter

The operator rents the annual use-right to land and buildings from an exogenous owner, custom contracts the entire husbandry operation from plowing through storage of the crop, and uses exogenous money for the annual fertilizer and seed expenses. The operator furnishes the miscellaneous money and all of the management. The returns in this maximum rental case are summarized in the second column of Table 1. The returns to the exogenous suppliers of investment, ownership, and labor are identified, as well as those to the operator.

Case 3: Part-investor-owner

The operator owns the land and buildings, with an exogenous investment of 40 percent (a mortgage). The operator does not own a combine, but custom hires the corn harvest and half of the labor required in the growing and storing operations. He uses exogenous money for the annual

Table 1. Three resource control cases

Item	Returns and costs per acre		
	100 percent investor	Renter	66 percent investor
	dollars		
Cash farm income	134.55	134.55	134.55
Noncash farm income	25.00	0	25.00
Total farm income	159.55	134.55	159.55
Cash operating costs:			
Land hire	0	46.82	10.83
Machinery hire	0	27.50	6.90
Labor hire	0	0	3.08
Operators annual cost	50.00	31.57	42.38
Interest, operating credit	0	.92	.92
Total cash operating costs	50.00	106.81	64.11
Net returns to operators			
Endogenous resources	109.55	27.74	95.44
Investment return:			
To operator			
Land and buildings	27.07	0	16.24
Machinery	3.15	0	2.45
Operating capital	1.75	.18	2.25
Total to operator	31.97	.18	20.94
To exogenous investors	0	31.79	11.03
Ownership return:			
To operator			
Land and buildings	29.74	0	29.74
Machinery	16.18	0	12.59
Total to operator	45.92	0	42.33
To exogenous owners	0	45.92	3.59
Labor return:			
To operator	8.69	0	3.08
To exogenous worker	0	8.69	5.61
Management return	9.36	9.36	9.36
Entrepreneurial return	13.61	18.20	19.73
Endogenous resources			
Land and buildings	451.05	0	270.63
Machinery	45.00	0	35.00
Operating money	50.00	5.25	64.16
Labor and management	18.05	9.36	12.44
Total endogenous resources	564.10	14.61	382.23
Exogenous resources	0	549.49	181.78
Returns ratios (endogenous)			
Returns/resources	0.194	1.899	0.250
Average investment return (percent)	5.85	3.43	5.66
Average ownership return (percent)	9.26	0	13.85

fertilizer and seed expenses and supplies all of the management. The returns in this more "typical" case are summarized in the third column of Table 1.

The bottom rows of the table include a listing of the value of the endogenous resources supplied by the operator, and those supplied by exogenous sources. The proportions of resources are quite different in these three cases. The last rows of the table are three ratios that measure operator returns to endogenous resources (about equivalent to the traditional category of "net income") and the usual rates of return to investment and ownership. Note that the operator in Case 2 has a slight investment return and no ownership return at all; that there is a small ownership return in Case 3 to the owner of the combine; and that the investment return in Case 1 is wholly to the operator, while in Case 3 it is split between the operator and the exogenous investors.

Does It Matter?

I hope that the data developed in the Table 1 speak for themselves, but I doubt that they do. I have found no farm production situations in which the system sketched above cannot be used to isolate and quantify returns to production resources. The Illinois data used here are detailed and make the accounting task a relatively easy one. If the base data were not so detailed, the researcher would have to fall back on interpolation and suffer the consequences in less reliable results.

In the final analysis, whether or not it matters that we can isolate and quantify resource returns must be a pragmatic valuation. I think that it matters, because the system allows us more understanding of real-world events than we otherwise seem to enjoy. The system allows us to generate useful insights into the production resource pricing phenomena that otherwise tend to appear either foolish or non-economic. We can add income tax and disinvestment variables to the above system and predict the growth or abandonment of land, cattle, and machinery leasing by operators. We can use this system to analyze the degree of perfection in various resource markets and to predict where the action will be, under assumed institutional changes.

It makes a difference whether a farm operator is a successfully leveraged entrepreneur, or a tractor driver who happens to own the tractor and the land it runs over, both free and clear. This difference is subject to economic analysis, even as Schumpeter thought it should be.

Appendix

Per Acre Base Data for Corn

Investment

Land: $400/acre investment; $600/acre current value.
Buildings and equipment: $24/acre current value.
Grain storage buildings: $29.62/acre current value.
Total investment value: land and buildings, $453.62.
Machinery, current value, $45 per acre.

Ownership

Land control, on share rent:
Gross rent, at one-half the crop, less one-half annual fertilizer and seed costs, $52.86.
Land taxes at .0122 of current value—$7.32.
Annual maintenance, buildings and equipment, $8.63.
Net rent on land, crop-share, $36.91.
Inventory changes, land:
Increase in land value = $25.00; depreciation on buildings and equipment = $5.10; net inventory change (noncash) = $19.90+.
Less investment return of $27.07/acre = net return to land ownership of $29.74/acre.

Machinery

Estimated gross rent = $24.48, less taxes of $0.65 = net rent on machinery inventory.
Inventory change: depreciation of $4.50 and investment return of $3.15.
Net return to machinery ownership = $16.18/acre.

Labor return

For growing, $5.82; for harvesting $2.53, for storing $0.34/acre.

Operating costs

For growing:	
tractor and machinery	$ 9.55
seed	3.74
annual fertilizer	18.22
manure	5.62
annual value phosphate	1.26
general crop expenses	3.99
Total growing expenses	$42.38
Harvesting:	
tractor	$ 1.08
custom hire	2.31
other machinery	4.23
Total harvesting expenses	$ 7.62
Total crop operating expenses	$50.00

Application of the Financial Management Function in the Family Size Farm Firm*

KENNETH R. KRAUSE

SUCCESS in family farm firms requires that the household farm-management complex make concurrent production and financing decisions to achieve realistic financial objectives set by the household. Economic theory of the firm has not evolved usable models in which the dynamics of production, capital, and finance are integrated [1, 5]. However, the increased rate of change in the mix of inputs used in production and marketing, lower profit margins per unit of output, firm growth, and income tax considerations are suggesting that researchers need improved insights on financial management, and farmers need improved financial management knowledge and skills. This paper is addressed to the newer areas of financial management in family-sized farm firms, a subarea and interrelated area of farm management.[1]

The Changing Role of Finance in the Farm Firm

The academic and research field of firm finance is evolving from one of describing instruments and institutions into a subdiscipline that encompasses development of rigorous financial strategies and analysis. Research, teaching, and application in farm firms now goes beyond analysis of procurement of funds to analysis of efficient capital utilization, which is an integrated part of the general management of a firm. The focus of farm firm finance is on risk-returns standards, the cost of capital, how the cost varies with financial decisions, the management of assets, the allocation of capital, and the valuation of the firm as a whole.

In the past, in farm management research and farmer decision making, considerable emphasis was placed on physical production of farm products. Addition to total cost or marginal cost of production provided a guide to determine the optimum level of production. Theory of the firm assumed an unlimited availability of equity funds, credit, or capital that is unrealistic in the real world. Marginal cost of finance is a useful criterion in finance decision making.[2] Instead of marginal revenue or returns from

---

[1] Family size for purposes of this paper implies a farm firm in which a single family supplies the major part of management and labor. Application of the financial management function varies by size, input, and product mix in family size firms; however,

KENNETH R. KRAUSE *is leader of the special financial analysis group, Farm Production Economics Division, Economic Research Service, USDA.*

sales, marginal return or efficiency of investment should be emphasized. The limit to profitable expansion of assets in the farm firm is reached when adding resources and money (marginal cost) equals the marginal returns to be obtained from the expanded firm [8].

The Household-Firm Complex

Limited attention has been given the household-firm complex in farm management research and teaching. The focus of attention has been upon management and management functions in the farm business. However, additional classification appears useful. The household and the farm firm may be viewed as separate entities. The household, some combination of man, wife, and children in family size farms, may be viewed as setting the financial and social objectives and goals. With less physical work by wives and children in the farm firm, the household farm firm separation is increasing. However, the two are coming together to an even greater extent through increasing cash withdrawal needs of the household from the farm firm.

Financial management at the household level is broader and more all-inclusive than in the farm firm. Successful financial management, whether at household or firm level, implies the ability to achieve the financial objectives set forth. In addition to allocation of resources for the farm firm, the household needs to consider farm and nonfarm business activities and investments, leverage-risk exposure levels, the types of farming to engage in, and household consumption levels.

The household may be viewed as the entrepreneurial unit in providing resources for the farm business. Farm management comes into play in the context of carrying out the objectives for the farm business, which are set at the entrepreneurial level within the confines of an existing set of resources; to change the set of resources requires a household, entrepreneurial management interplay. When the resource bundle is changed and particularly when expanded, the management input may have to change; it may be continuous or discontinuous.

Most important, farm firm financial decisions are long term and involve setting financial objectives for the farm firm, desired growth rates, growth paths in terms of commodity selection, internal and external financing, and how resources are to be controlled; e.g., through ownership, rental, or hire of a package of services, or some combination of the three.

---

major differences in application of the financial management function appear between family size firms and larger than family size firms. The differences are in part due to the nature of the credit and equity markets used by various sizes and types of firms, the level at which contracts are negotiated between farm and physical input and marketing firms, and the management decision-making aids available to family size firms as opposed to very large firms.

[2] Several items enter into determining the marginal cost of finance in a dynamic context such as the interest rate, finance charge, opportunity cost on equity and the cost of liquidity.

The farm business has been the predominant type of business and has claimed most of the ownership and investment activities of the household-entrepreneurial complex in family size farms. However, nonfarm resource ownership and investments are made at the household level and may become more competitive with the farm business as the family farm household becomes more knowledgeable on nonfarm investments. The financial management function for nonfarm activities is similar to farm activities; specific application changes with the nature of ownership, investment, and the dynamics of the specific nonfarm activity.

Financial management is an integral part of the overall household planning and entrepreneurial process. It is particularly relevant in analyzing potentials relative to goals selected by the household, devising resource acquisition and allocation strategies to bring closure between potentials and goals, establishing operating goals, measuring results against goals, and instituting adjustments to reach desired goals.

The Farm Financial Management Function

Examples of several interdependent management functions of the farm firm are: (1) physical production, (2) labor, (3) procurement, (4) marketing, (5) financial, and (6) overall coordination and direction of the business. The household or entrepreneurial unit performs or delegates each of the functions. In family size firms, the entrepreneurial role and all of the management functions are often vested in one individual. However, each function must be completed; and for research, teaching, and farm management purposes, we can single out the financial management functions and concentrate on them just as we previously focused upon production and labor management.

The farm finance function includes: (1) obtaining the desired flow of resource services and managing the services, which might include land, machinery, other capital stock and credit; (2) management of investments; (3) information flows, which might include records, accounts, etc.; and (4) planning and control processes. In terms of decision making, the financial management function involves investment decisions and financing decisions. Major investment decisions for the farm business are made at the household level and are concerned with the magnitude and composition of owned assets and the business-risk mix of the firm and relate to operation and expansion strategies [2, 4, 7, 11].

Financing decisions involve the use of equity and credit and become important when production and capital theories are integrated since financial resources require allocation and management; the firm faces financial constraints imposed by the current state and uncertainty of new technology and the input and product markets. Investment and financing decisions are related and must be determined simultaneously, since investment in resources relates to credit availability, leverage, risk exposure, capital cost, and income. Financing and investment decisions in family firms are often made in cooperation with a financial institution, resource supplier, or marketing firm.

Economies in Financial Management

Several continuous processes are involved in farm financial management, which is now demanding more time and improved interpersonal skills on the part of family size farmers.

Advances in business management concepts and techniques are developing a recognized area of business technology that can be applied to farm investment and finance decisions. In industrial firms, planning and daily operations are often separated; e.g., the executive overall management role is organized around functions, whereas daily decisions in terms of financing immediate product production and marketing are organized around commodities. Economies of management may be achieved in both executive and operating roles [9]. In family size firms, long-term financial planning is an executive function; economies in the executive function are conceptually available in terms of long-term planning—both for a production period and for intermediate and long-term life of the firm. Rigorous long-term executive plans provide a guide for daily executive decision making. Development of alternative long-term strategies, including knowledge of what resources will become available and under what terms, can provide short-term economies in the executive function; e.g., if plans and consequences are developed, the farm firm or household has only to examine immediate conditions in terms of long-term plans to make an executive decision.

Operating management is associated with the short-run operation of the farm business in terms of the physical production job and adjusting to changing climatic, input, and price conditions and resources that become available. Financial flexibilities and efficiency can be achieved in the short run in a setting of preplanned financial arrangements; e.g., prearranging for financing of fertilizer, machinery services, etc., that may be needed during a production period. Since weather, price relationships, and resource availability often change rapidly in the short run, the major financial management operating economies appear most likely to come from work that is done at the executive level prior to actual operation.

Public Assistance for Financial Management

Given the pressing public social demands on the domestic economy, public assistance for farm management work may have low priority for additional funds. However, given public research and public agencies that may be available for family farm business assistance, financial management should rate high on the priority list. Work both in assisting the farm family to achieve its financial goals and in assisting the public to achieve resource use goals would be useful [3]. Family farmers can obtain increased financial management capacity in several ways. Public agencies and institutions active in providing farm management assistance to farmers need to reevaluate their role and learn how to more effectively provide financial management assistance.

Farmers, in some cases, can reduce financial management time requirements through hire of mechanical tasks, such as recordkeeping, feed formulation, fertilization levels and mixes, and even decision making on what and how much to produce. However, farmers cannot generally hire financial management skills and integration of financial outcomes. Advances in electronic data processing and application through public establishments and private firms can assist farmers in both short- and long-run financial management work. The degree of public support for development and operation of electronic data processing for family size farmers, in which a highly skilled analyst plus supporting help may be needed for 20 to 30 farmers, has not been determined. However, the importance of potential developments suggest that more analysis on the public role should take place soon.

In the absence of public guidance, individual family size firms will continue to use and exploit resources that will optimize individual financial and personal objectives but thay may be in conflict with public objectives. Only two areas for consideration are discussed: (1) real estate use and (2) credit use and availability. From both an individual and public point of view, the real estate rental and sales markets are not well developed and few farmers know about real estate available for sale or rent outside of their immediate neighborhoods.[3] Few family farmers conduct rigorous short- or long-run analyses of the availability of land for purchase, cash rent, or share lease in their geographic areas as part of their short- and long-term planning. What would be the payoff from teaching farmers how to evaluate the availability of resources? What would be the payoff from developing improved market news of available farm investments and financial resources?

Measures or indices of family size farmers' ability to use credit and to obtain various rates of growth have not been developed.[4] Without even crude measures, individual credit institutions have limited opportunity to bid on credit extension to a large number of farm households. Farmers, likewise, have very limited knowledge of credit that could be available to them under various terms. Improved measures of success in farm credit use should be useful to farmers and farm lenders and other resource suppliers.

---

[3] Comparison with advances in reporting market news for livestock, grains, fruits and vegetables, and even farm credit, where public assistance helps to provide daily price and quantity and quality quotations, indicates that information on real estate and credit markets could be improved.

[4] Advances in industrial development and application of subprofessional, professional, and management selection scales appear to hold potential application in the farm credit field. Credit extension indices might include probabilities of repayment for various types of enterprises and loan magnitudes [6].

Summary

The financial management function does not replace traditional management functions and processes; rather it modifies and adds to the overall role of management in the family size farm firm. Financial management will require more management time and improved skills and information.

Farm entrepreneurs may need to redirect emphasis from physical production, where extensive knowledge of alternative outcomes is available, to the financial management function, where knowledge is not readily available and where farmers have limited knowledge of credit and capital availability and alternative outcomes from use of credit and capital. Family size farmers have become adept at developing physical production strategies to cope with climatic and disease phenomena. They now need to develop equal sophistication on financial management strategies to meet the household's financial objectives.

Agricultural economics research alone and with interdisciplinary efforts can assist the farm family with farm financial management research through more clearly identifying household financial goals; through analysis of alternative ownership, investment and operating strategies; and through evaluation of required managerial capacity. Research can also help to design more effective ways for farmers to gain access to managerial capacity and more effective educational programs. Such work can yield larger dividends in the future than past work on production strategies is now yielding. Rigorous attention to means of resolving possible conflicts between private financial objectives and public objectives can help to insure an improved domestic environment.

Income Tax Planning for Farmers*

HOY F. CARMAN

AN assignment to discuss income tax planning for farmers at a time when major tax reforms are being considered is a difficult, but, I must add, interesting task. I use the word interesting, but one can rest assured that many tax advisors, management companies, and investors use stronger descriptive terms. Football coaches respond to rule changes with new or revised strategies. I expect tax reform to lengthen the working day of many tax consultants as they devise new "quick openers" and "end sweeps."

This paper will discuss some farm tax planning opportunities that have existed during the last several years. Tax provisions used in tax loss farming will be emphasized. The principal features of proposed tax reforms as applied to agriculture will be summarized and some probable effects will be discussed.

Special Farm Tax Provisions

Farmers face the same problems as other taxpayers, plus a few that are unique.[1] But special income tax provisions that are applicable to farmers offer favorable tax planning opportunities as well as problems—opportunities that revolve primarily around the use of cash accounting. Cash accounting, combined with accelerated depreciation, full deductibility of farm losses from income, timing of income and expenses, and capital gains provisions on agricultural assets, has been used by farmers and ranchers as well as nonfarm investors to maximize after-tax income.

Ordinary income can be shifted to capital gains in a fairly systematic manner with proper planning. The income shifting opportunity is afforded to farmers building up a herd of livestock, establishing an orchard or vineyard, or improving a parcel of land with soil and water conservation improvements. Most expenses, even though they add to the value of these assets, are deductible at the time incurred.[2]

Tax Planning

I have found surprisingly little written on farm tax planning with a planning horizon of more than two tax years.[3] Most publications dealing

with farm income tax management are concerned with depreciation methods, timing receipt of income, timing of input purchases, and full deduction of expenses [8, 10, 15]. Farmers who recognize the need for longer term tax management have typically sought out professional services of tax consultants and management companies. Most farm tax provisions have wide applicability, but optimum utilization can be quite individualized.

Most farmers have benefited in one way or another from special farm income tax provisions. However, it is probably safe to say that few farmers have utilized these provisions in a systematic manner over time to convert ordinary income to capital gains.[4] Farmers have not traditionally found themselves in the highest tax brackets where the advantage of capital gains income is greatest. Tax consultants and management firms, however, were quick to recognize the value of agricultural enterprises such as citrus and cattle for their high income clients and devised programs that exploited farm tax laws. Promotional materials of management companies and articles in business publications, such as *Fortune* and *The Wall Street Journal* have emphasized the tax advantages of agricultural investments [4, 3]. What high tax bracket investor can resist, for example, the detailed description of a stockbroker who realized a two-year after-tax return of 39 percent on a $35,000 investment in breeding cattle [3].[5] The same story reported that "at least eight corporations, plus dozens of individual farmers who also manage property for a fee, now handle well over $100 million of investments for more than 5,000 people." Much of the growth of these firms has occurred during the last three or four years.

Tax Loss Farming

Capital gains provisions, tax treatment of certain types of farm expenses, and cash accounting form the basis for successful "tax loss farming" or "tax sheltered investment in agriculture."[6] The incentive for tax sheltered investments is provided by the difference in tax rates between ordinary income and capital gains.

---

conservation is limited to 25 percent of gross income from farming for the year. Any unused deduction can be carried over to succeeding years [15, p. 39]. Land clearing expenditures can also be deducted. The deduction in any year cannot exceed $5,000 or 25 percent of taxable income from farming, whichever is less, and the balance must be capitalized [15, p. 23].

[3] A noteworthy exception is the excellent analysis by Dean and Carter [7].

[4] I know of a farmer who has built up a substantial net worth while paying no federal income taxes.

[5] A budgeted example for a six-year investment in beef breeding cattle, based on cost, price, and tax levels effective in 1967, illustrated that an investor in the 70 percent tax bracket could realize a simple after-tax return of approximately 14 percent on invested capital [6]. The rate of return decreases for investors in lower tax brackets.

[6] Other tax provisions form the basis for very popular tax sheltered investments in apartment houses and in the oil industry, e.g., liberal depreciation rules and percentage depletion allowances.

Several agricultural enterprises offer tax shelter opportunities. These include livestock, development of orchards, groves, and vineyards, and some land improvements. The method of operation is similar for each enterprise. The farmer or investor builds up a herd of breeding or dairy animals or improves land. Cash accounting is used, and expenses are deducted from income, farm or nonfarm, at the time incurred. The tax basis of the raised livestock held for breeding or dairy purposes and the land improvements is zero. Thus, any gain realized from the sale of these assets is capital gains. After-tax returns for these investments increase as the marginal income tax bracket of the owner increases and as the ratio of capital gains to expenses increases.[7] Careful planning can result in an attractive return to the nonfarm investor from tax sheltered investments in agriculture. A growth-minded farmer or rancher can also use these tax provisions to build up his net worth with a minimum income tax liability.

Tax shelter investments are much more profitable for high income than for low income taxpayers. This differential in profitability permits low income farmers to execute mutually advantageous contractual arrangements with high income investors. Contractual arrangements are facilitated by management companies who for a fee (tax deductible) arrange for farmers to care for the farm property of investors. Polson found that a group of Oklahoma ranchers had higher after-tax returns for each of the years 1962-1967 with cattle cared for under a contractual arrangement than with their own cattle [12]. It is important to note that the after-tax cost of establishing an orchard or improving land decreases with increases in the tax bracket of the developer. This presents interesting possibilities for orchard development. The level of taxable income of buyer and seller in seller-financed land sales is an important consideration since interest is tax deductible for the buyer but ordinary income for the seller. For a given outlay on an installment contract the buyer will prefer the highest permissible allocation of sales price to interest. Differences in tax brackets of the buyer and seller may make adjustments in the sales price and allocation to interest profitable for both parties to the contract.

Proposed Income Tax Law Changes

Agriculture is one of the areas chosen for early tax reform efforts. What started out as an effort to limit tax-loss farming by wealthy urban investors appears to have become an effort to tighten up income tax rules applicable to all farmers.

Let us briefly consider some tax reform proposals applicable to agriculture. A Treasury Department recommendation prepared during the Johnson Administration called for limiting to $15,000 the amount of farm losses that could be deducted from nonfarm income [13]. Senator Metcalf (D-Montana) introduced a bill in the Senate that also would limit the deduction of farm losses from nonfarm income but is more restrictive than the Treasury Department proposal. Under this bill, a taxpayer with $30,000 or more of nonfarm income could not deduct any losses from nonfarm income.[8] The impact of these proposals on most full-time farmers and ranchers would be minimal. Tax shelter investments in agriculture would be sharply curtailed under the Treasury proposal and would no longer be profitable under Senator Metcalf's bill.

---

[7] For discussions of the effect of tax bracket and recovery of expenses on returns from tax shelter investments, see [5, 6].

A comprehensive tax reform bill has been passed by the U.S. House of Representatives and sent to the Senate. Under its provisions, as I have seen them reported, the size of individual tax shelter investments in agriculture would be limited. In addition, the incentive for tax shelter investing would be somewhat restricted by changes in tax rates and capital gains provisions. Tax rates would be reduced, the capital gains tax rate would be half of the ordinary rate but with no maximum, and the holding period to qualify for capital gains would be lengthened.

Limitation of tax loss farming would be accomplished with the requirement for an "Excess Deductions Account." Taxpayers with nonfarm income over $50,000 would have to place farm losses above $25,000 per year into this account. The taxpayer would then have to pay ordinary tax rates on the Excess Deductions Account before claiming capital gains on breeding livestock, orchards, and land improvements. It is also reported that the definition of a "hobby farmer" (who is denied write-off of losses) would be anyone who loses $25,000 or more annually from farming for a period of three years. These provisions would not affect the profitability of tax loss farming but would limit the size of individual investments. The provision of an Excess Deductions Account should have little effect on the full-time farmer.

A change in the rules governing capital gains on livestock would increase taxes for some farmers and ranchers but would have little effect on method or size of operation. It would require that livestock be held for at least one year after first being used for draft, dairy, or breeding purposes to qualify for capital gains. Depreciation on purchased livestock would become subject to recapture provisions as ordinary income when there is a profit on subsequent sales. Each of these provisions, if enacted, would reduce the profitability of tax shelter investments in livestock enterprises.

Gains in land values that are the result of soil and water conservation expenditures would be subject to ordinary income tax rates for five years after the expense was incurred. While I have seen nothing regarding orchard establishment expenses, it is reasonable to expect similar regulations. This would lengthen the holding period of some tax shelter investments in land but would have little effect on farmers improving land or establishing orchards.

---

[8] The bill (S. 4059) provides that for a taxpayer engaged in farming, the deductions allowable shall not exceed the sum of (1) the adjusted farm gross income for the taxable year, and (2) the higher of either the amount of special deductions or $15,000 less the amount of nonfarm income over $15,000. These provisions will not apply to farmers using accrual accounting [14, pp. A-108 and A-109]. A companion bill (H.R. 19916) was introduced in the House of Representatives by Mr. Culver [14, pp. E-302 and E-303].

Summary

Profitable tax planning opportunities exist in agriculture, especially in the conversion of ordinary income to capital gains. Farmers have benefited from farm tax provisions but not in the spectacular manner of some wealthy urban investors. The tax reform bill passed by the U.S. House of Representatives would serve to reduce the size of tax shelter investments, as well as their profitability, while allowing farmers to continue their use of cash accounting. We have no way of knowing what action the Senate will take on tax reform. I feel confident, however, that even with tax reforms, farmers can profit from the type of income tax planning just described. Good financial records, familiarity with income tax law, and occasional professional advice will help score points in the tax management game.

VIGNETTES: RURAL DEVELOPMENT, DEMOGRAPHY

CHAIRMAN: JAMES M. STEPP, CLEMSON UNIVERSITY

General Hospital Facilities in Michigan, 1965

LEON B. PERKINSON

IT IS commonly assumed that rural areas have fewer beds per 1,000 population than urban areas. With rapid net outmigration from rural areas, this supposition may be no longer true. The purpose of this study was to determine the availability of general hospital beds and the variation in availability by degree of rurality.

Licensed capacity, an approximation of facility quantity, of hospitals by type of bed, was obtained for each county.[1] Licensed capacity does not measure underutilization, overcrowding, or quality of facilities.

Non-public hospitals, such as military base hospitals, federal and state veterans' facilities, U. S. Public Health Service hospitals, and student health facilities, were excluded from the analysis. Mental, long term or rehabilitation, and tuberculosis (TB) beds for "public" hospitals were also excluded because of the specificity of location for such services. Hospitals with mental or TB facilities were located in counties with a town of 5,000 or more and within 25 miles of a Standard Metropolitan Statistical Area, with the exception of Marquette County. Marquette could be considered the central place of the Upper Peninsula. The long-term facilities were all located in areas with a town of at least 5,000 population or were within 25 miles of a SMSA.

Method

An ordinary least squares linear regression (OLS) was used in the analysis. The dependent variable was the number of general hospital beds per 1,000 population, and the independent variables were 13 socio-economic characteristics. This equation was processed through an OLS delete routine with a ten percent minimum significance required for each variable in the basic equation (equation 1, Table 1). Dummy (0,1) variables representing measures of rurality were added to the basic equation (equations 2-4, Table 1).

A non-linear (logarithmic) form was also used following the above steps,

---

* Significant at the 1 percent level.

** Significant at the 5 percent level.

*** Significant at the 10 percent level.

[a] Terms in parentheses are the standard errors of the coefficient.

[b] Dummy variable with 0 = existence of town of 5,000 population, 1 = no town as large as 5,000 population.

[c] Variable formed from the dummy variables for geographic location. 0 = not in specific geographic area; 1 = in specific geographic area. A = (Upper Peninsula—Northern Lower Michigan); B = Upper Peninsula + Northern Lower Michigan—2 Southern Michigan). For the derivation of each area coefficient, see text footnote 2.

[d] Variable formed from the dummy variables for distance from a city of 25,000 population (1960). 0 = not in specific distance class, 1 = in specific distance class. C = ($\geq$25 miles $<$50 miles) − ($\geq$50 miles), D = ($\geq$25 miles $<$50 miles) + $\geq$50 miles) − 2($<$25 miles). For derivation of each distance coefficient, see text footnote 2.

but it had lower explanatory powers, larger coefficient errors, and used more variables than the linear form. Therefore, only the linear results were used.

The basic equation (equation 1, Table 1) indicates a direct relationship between the number of hospital beds per 1,000 and capital expenditures on health and hospitals, but inverse relationships with the relative change in population, percentage of the employed labor force working outside the county, and the percentage of the population age 60 or over. The estimated number of hospital beds for a county with mean values for each variable was 3.662 per 1,000. The state average number of beds per 1,000 was 3.657 in 1965.

The relationship between capital expenditures and number of beds is self-explanatory. But the inverse relationships with the other variables are revealing. Apparently, areas with greater than average growth have not been able to increase facilities as rapidly as population increased through migration. Areas with a decreasing population, on the other hand, might have a larger relative number of beds without any expansion of facilities.

The inverse relationship between the percentage of the employed labor force working outside of the county and number of beds indicated that the number of beds per 1,000 population decreased as the percentage of "outside" workers increased. Is it possible that workers who were geographically mobile in obtaining employment were also geographically mobile in the acquisition of hospital care, so far as the relative number of beds are indicative of such care? Or are the economic forces that stimulate a higher percentage of the labor force to seek outside employment similar to those forces which may "cause" fewer hospital beds? If worker mobility is indicative of the relative mobility of the population in obtaining hospital care, the pressures from an expanding population in growth areas may be compounded.

The relative number of beds decreases as the percentage of population age 60 and over increases. It is assumed that older people need more hospital services, so this inverse relationship is unfortunate. In Michigan, the rural counties generally have a greater proportion of older population; and, given the usual assumption that rural areas have fewer hospital facilities, the results are consistent.

Dummy Variables

The results (with the exception of population change) are consistent with the assumption that rural areas have fewer beds than urban areas. However, the degree of rurality in terms of population and geographic location alters this assumption. A larger town located in an isolated area may provide hospital facilities for residents in contiguous counties. Therefore, the number of hospital beds per 1,000 population in such a county may exceed those found in rural counties without such a town. Dummy variables measuring "degree of rurality" were developed: (1) a town as large as 5,000 population located within the county; (2) geographic location—Upper Peninsula (UP), Northern Lower Michigan (NLM), Southern Michigan (SM); (3) distance from a city of 25,000—less than 25 miles, between 25 and 49 miles, and 50 miles or more.[2]

The signs of the variables already discussed did not change when the dummy variables were included in the model (equations 2-4, Table 1). Using equation 2, with no town in the county as large as 5,000 population, the estimated number of hospital beds for a typical county would decrease by 26 percent.

With all variables in equation 3, except the dummy variables, at their means, the estimated number of general hospital beds per 1,000 population for counties with a town as large as 5,000 were: UP, 4.5; NLM, 5.0; SM, 3.6. When no town as large as 5,000 was present, the estimated number of beds for each area decreased by approximately 1.5. In equation 4, the estimated number of hospital beds per 1,000 for a county with a town larger than 5,000 population increases with distance from a city of 25,000: less than 25 miles, 3.5; 25 miles but less than 50 miles, 4.3; 50 miles or more, 4.6. With no town as large as 5,000 in the country, the estimated number of beds for each decreased by approximately 1.3.

Relaxing the *ceteris paribus* assumption for a town of 5,000 population, a different hierachy appears. Ninety percent of the counties within 25 miles of a city of 25,000 had a town as large as 5,000. Fewer than one-half of the counties more than 50 miles from a city of 25,000 population had a town as large as 5,000. If one compares the estimated 3.5 beds per 1,000 population in counties with a town of 5,000 and less than 25 miles from a city with the estimated number of counties without a town of 5,000 and 25 to 49 miles (3.0 beds) or more than 50 miles (3.3 beds) from a city, the results parallel the usual assumption.[3] These "typical" counties show fewer facilities in rural areas.[4]

---

[2] The formats for both the geographic and distance variables are illustrated in footnotes 4 and 5, Table 1. The values of the (0, 1) variable were derived for each county by inserting a value of unity for the appropriate class and zero for the remaining classes. For example, the amount that is either added to or subtracted from the constant term for each geographic characteristic (equation 3, Table 1), is derived as follows: Upper Peninsula $= (-.273) + (.360)$; Northern Lower Michigan $= -(-.273) + (.360)$; Southern Lower Michigan $= -2(.360)$. The Upper Peninsula of Michigan is quite rural; southern Michigan is the most urban. The distance variables are derived from equation 4 in the same manner. For other uses and more detailed explanation of this method, see [1, pp. 34–36, 72–75].

[3] Similar results were obtained for the geographic variables (UP, NLM, SM) differences when the ceteris paribus assumption for a town of 5,000 was relaxed. However, rural areas having a town as large as 5,000 had considerably greater bed availability than those without a town of 5,000.

[4] Public hospital beds previously excluded would establish a downward bias in the availability of overall hospital beds per 1,000 population in urbanized areas. The deletion also established a downward bias for the coefficient related to town of 5,000 population, as all but one of the special care facilities were located in such a county.

The results for distance are expected if one assumes an area is more likely to furnish its own facilities the greater the distance to a relatively large city. These findings indicate the usual hypothesis that rural areas have fewer hospital beds relative to population than urban areas is too simple. It appears that there are more general hospital beds available per 1,000 the greater the distance a particular county is from a city of 25,000.

The result of this study shows that adjustments need to be made for counties having a city of 5,000 or more population. These counties have more hospital beds per 1,000 population than counties adjacent to cities of 25,000 population or to other more rural counties.

Conclusion

The usual assumption that rural areas have fewer general hospital facilities than urban areas needs to be modified. Accounting for discrete characteristics featuring degrees of rurality, the general assumption does not hold. Rural counties with a town of 5,000 would be expected to have more, rather than less, general hospital beds per 1,000 population than its urban counterpart with identical characteristics. This holds regardless of whether one measures rurality on the basis of geographic location or distance from a city of 25,000 population.

If these results hold for other states as well, important modifications need to be made in the general observation that service levels are poorer in rural areas. Rural counties with a town of 5,000 or more may actually have better service levels. This conclusion assumes, as do most such studies, that quantity is synonymous with quality.

Local School Expenditures and Educational Quality: A Correlation Analysis*

THOMAS F. STINSON AND EDWARD F. KRAHMER

A MAJOR factor contributing to the viability of any community is the quality of its educational system. This factor takes on an added dimension in rural areas because many of today's national social problems are thought to be due to the inadequate elementary and secondary education provided to residents of rural areas. Urban problems have been compounded by the migration of poorly educated workers from rural America. And, at the same time, efforts to develop rural economies and reverse the population flow are often hindered by low quality schools. To compound the problems, as rural communities have declined the resources necessary for providing adequate education to the remaining residents have diminished and the quality of the school system has continued to deteriorate.

Because of its importance, there has been considerable research done on ways to measure and improve education. Many have focused on the field of educational finance, assuming that the amount a school district spends has a very strong impact on the quality of the local school system. Benchmark surveys have been made showing national or regional differences in spending for education. Attempts have also been made to determine which social and economic characteristics are associated with increased levels of spending for education, such as those of Miner [2] and Shapiro [4]. Finally, there have been attempts to determine whether economies of scale exist for education, and if they do, to determine the optimum size school. Both Hansen [1] and Riew [3] have completed this type of study.

A major problem facing all research in this field has been obtaining an adequate measure of the quality of the local educational system. Usually researchers have been forced to assume that per capita or per pupil expenditures bear some direct relationship to education quality and to continue their research on that assumption. There has, however, been almost no testing of the hypothesis that expenditure per pupil or expenditure per capita is a useful and accurate measure of the quality of education.

This paper reports the results of a test of the assumption that per pupil expenditure bears a significant relationship to educational quality. In addition, the relationships between several alternative measures of expenditure and educational quality were examined.

Procedure

The Iowa Test of Educational Development, a standardized educational achievement test, was given in more than 80 percent of North Dakota's school districts during 1965 as part of a statewide survey of education. At the same time, extensive educational finance data were collected from each school district. The availability of this data made a test of the correlation between expenditures and achievement test scores possible.

Twenty-four separate expenditure variables were correlated with composite achievement scores for 9th graders, 11th graders, and for the combined 9th and 11th grades to determine which measures of expenditure were related to educational quality. The expenditure variables used were in the form of a fraction, with six possible numerators and four different denominators. The numerators were: (1) instructional cost, which included only expenditures for salary of teaching and custodial personnel, textbooks, audio-visual aids, teaching supplies, and other expenditures relating directly to instruction; (2) operating cost less transportation, which included (1) plus school health expenditure, as well as other operating expenditure not directly connected with instruction; (3) operating cost, which included (2) plus transportation costs; (4) total operating cost, which included (3) plus outgoing transfer payment;[1] (5) total operating cost less transportation cost; and (6) total cost, which included all costs, both current and capital, for the school district.

The denominators used were: (1) the number of students enrolled in the district; (2) a revised number of students obtained by weighting high school students by 1.25, to adjust for the greater cost of educating high school students; (3) the number of teachers; (4) a revised number of teachers, obtained by weighting the number of high school teachers by 1.25.

The last two denominators were used to test the hypothesis that the relevant variable is the amount of resources brought to bear on a classroom unit rather than on an individual student. These denominators reduce distortions caused by small differences in student-teacher ratios that do not provide increases in quality. This is especially important in rural areas where small class sizes may force per pupil costs above the national average without providing an average quality education.

The per teacher measure also fits well with current educational theories about what factors contribute to the quality of the educational system. The largest portion of per teacher expenditure goes for the teacher's salary, an item that reflects both the experience and the education of the teacher. The residual reflects the books, audio-visual materials, and other teaching aids which each teacher has to work with.

Product moment correlations were computed for each of four size

---

[1] At present, this is the best figure that can be obtained from the Census of Governments, the only consistent set of national figures.

Table 1. Correlation between various measures of expenditure and composite score on the Iowa Test of Educational Development, by size of high school, rural high schools in North Dakota, 1966

Measure of expenditure[a]	Size of high school								
	100–199 Pupils[b]			200–400 Pupils[c]			100–400 Pupils[d]		
	Grade			Grade			Grade		
	9	11	9 and 11	9	11	9 and 11	9	11	9 and 11
Per pupil:									
Instructional cost	.143	.068	.087	.098	.163	.184	.108	.063	.070

[b] $N=41$

[c] $N=25$

[d] $N=66$

groups of high schools, measured by enrollment: less than 100, between 100 and 200, between 200 and 400, and those between 100 and 400. Although no significant results were obtained for districts with high school enrollments of less than 100 students, statistically significant correlations were obtained for both 9th and 11th graders for districts with high schools with 100-200, 200-400, and 100-400 pupils.

Findings

Detailed results of the study are shown in Table 1. The most important findings appear to be these:

(1) A statistically significant correlation exists between some measures of per teacher expenditure and composite pupil achievement test scores. In order of their apparent significance, the three most useful measures are instructional cost, operating cost less transportation, and total cost less transportation. This correlation appears consistent among grades and among different sizes of high schools.

(2) No statistically significant relationships exist between any measure of per pupil or revised pupil spending and achievement test scores.

(3) If transportation costs are not separated from operating costs, no significant correlations exist between expenditures and achievement test scores.

Conclusion

This study does not provide the answer to the question of how to improve rural schools. Much study and research remains before any such answer can be obtained. Its findings do suggest, however, a new approach for both research and operating programs concerned with small rural school districts. It appears that the total funds available for use in a classroom unit, rather than the funds used per pupil, is the significant variable for studies of educational finance.

These results, if applicable on a national basis, suggest changes in the orientation of operating programs and future research. State aid programs designed to bring poorer school districts up to a minimum level of per pupil expenditure appear to be open to criticism. It appears that a program designed to provide a minimum level of per teacher expenditure, while keeping the pupil-teacher ratio within acceptable limits, might be more successful in improving the quality of education in those districts.

The Farm Poor: Counted, Miscounted, or Discounted?

O. Wendell Holmes

Charles Dickens, in *A Tale of Two Cities*, opens with the statement, "It was in the best of times, it was in the worst of times, . . . it was the spring of hope, it was the winter of despair. . . ." This perhaps echoes the sentiment of many people in the United States today. Our economy is in the best of times for many but in the worst of times for others. For some, their economic position puts them in a real spring of hope. For others, their future appears as a winter of despair.

In order to more equitably share the wealth of our nation with its less affluent citizens, guidelines are needed to determine who the less affluent are, what constitutes poverty, and what some attributes of the poor are.

Lack of financial resources is the handiest explanation of poverty. The current definition has been built around income: How much is necessary to maintain a family of four persons at a given level of living. This definition of poverty was developed for use by the Council of Economic Advisers in the President's war on poverty. Later the Social Security Administration (SSA) developed a poverty line centering around $3,000. In this definition, a family of four was considered "poor" if their total annual cash income was less than $3,000; a single unrelated individual, if his annual income was less than $1,500 [4]. The SSA refined this definition by including such variables as family composition, sex of head, and place of residence, (farm or nonfarm). The resulting poverty index is the officially adopted poverty definition of the Council of Economic Advisers and the Office of Economic Opportunity.

In 1955 the Household Food Consumption Survey indicated that families of four persons, regardless of income level or place of residence, spent about one-third of their annual income on food. It was thus assumed that an income of at least three times the cost of the economy food plan was necessary to keep a family out of poverty. Using the economy food plan, as developed by the USDA, and a multiplier of "3," as obtained from the 1955 survey, a poverty cutoff level was established. Thus, if the food plan was priced at $1,000, the resulting income would be $3,000. Any family of four with an income of less than $3,000, spending $1,000 or more for food would be considered to be in poverty.

This same survey showed that about 40 percent of food consumed by farm families was produced at home. This means that the average farm

---

O. Wendell Holmes *is an agricultural economist with the Economic Research Service, USDA.*

family would produce about $400 worth of the $1,000 total food budget, and hence need 40 percent less cash for their food expenses. The food budget for farm families was thus determined to be $1,000 minus $400, or $600. This $600 figure was then used as the cost of the food plan and was tripled to get a farm family poverty income level of $1,800. For nonfarmers the poverty income level was $3,000.

Data from the 1961 food consumption survey showed that home production of food items by farm families had decreased to about 30 percent of their food needs, in dollar value. The poverty line for farm families was then adjusted to take this into consideration. Using the same food plan as before as an example, the new food budget for farm families was $1,000 minus $300, or $700. This $700 food budget was then multiplied by 3 to give a farm poverty income cutoff of $2,100. This is the 70 percent poverty level. The cutoff for an urban family was the same as before, $3,000.

A number of weaknesses in the method employed in determining the farm poverty cutoffs seem obvious. The food plan used here was designed by the USDA using data from the National Research Council for temporary or emergency use when funds are low [5]. There is no provision for improving the diet of the poor in this food plan.

The main weakness is the manner in which this method tends to discriminate against the farm poor. Because of the assumed ability of a farm family to produce 30 percent of their food (in dollar value) it was incorrectly assumed that a farm family needed only 70 percent as much income as a nonfarm family. Currently the food plan for a family of four is valued at about $1,100. The value of home produced food (in this case $330) is then subtracted from the cost of the food plan. The result, $770, is then tripled giving $2,310 as the poverty threshold cutoff level for farm families. What started out to be a $330 deduction, because of the benefits of home produced food, ended up as a $990 deduction from the farmers income, or an implicit assumption that the farmer produced 90 percent of his food needs.

The current food budget of $1,100 needs to be changed to account for recent increases in the cost of food. The current (1969) cost of the minimal nutrition diet for a family of four is now computed to be $1,284 per year. Using the multiplier of "3" on this figure would raise the poverty cutoff to $3,852 [1, p. 290].

As mentioned earlier, using the 70 percent level tends to discriminate against the poor in that many are declared to be out of poverty by definition only. However, the people not counted at the 70 percent level (but included at higher levels) are just as poor as ever. Because they are excluded from the poverty rolls means there are by definition fewer rural people in poverty. With fewer rural people on the poverty rolls and with their scattered residence, they are hard to identify. They are virtually without the experienced leadership or organization necessary to give them the voice or vote they need to gain either national recognition or political bargaining power. Thus, the number of programs and funds earmarked for the rural poor may not be as large proportionally as it is for the urban poor. In 1965, only 18 percent of the Community Action Program (CAP) grants went to the rural area programs. This increased in 1966 to 25 percent and in 1968 to 30 percent. While the percentage of CAP grants going to rural areas has been increasing, it is still low considering that 43 percent of the nation's poor are rural residents [2].

The differential, as currently used, discriminates against rural children and youths, the target groups who should receive the greatest assistance. Since eligibility for programs such as Upward Bound, Headstart, and Family Planning is contingent on being in poverty, many farm families are denied such programs since they have been defined out of poverty.

To assume that farmers need only 70 percent as much cash income as urban families is incorrect. Comparable living standards in the country would probably cost as much as in the city. Frequently the assumption is made that rural living is much cheaper than urban living. That assumption is valid only if one assumes that a lower standard of living is appropriate in rural areas [3]. In 1961, for example, among families with less than $3,000 annual income, farm families whose average annual income was nearly $700 less than that of urban families spent nearly the same dollar amount for transportation and nearly seven percent more of their income on transportation. Farm families often pay larger shares of medical expense out of pocket, while nonfarm families may profit from fringe benefits such as medical insurance and other advantages offered as part of their employment.

Because of the less developed infrastructure where the low income population is likely to be concentrated, other costs may significantly influence their lives and outlook. Among these other costs are: inadequate educational institutions, poor housing, and the complex of factors related to it, such as plumbing, lighting, fuel and heat. A lack of community institutions, or social and physical access to them, constitutes both direct and indirect costs which contribute to the general cultural milieu of poverty linked conditions.

Data from the 1967 Current Population Survey of 1966 Income shows clearly the effect of various percentage differentials on the number of persons who will be defined into poverty. Using the 70 percent level, the total number of persons in poverty, both farm and nonfarm, in 1966 was 29.9 million. The President's National Advisory Commission on Rural Poverty in its report, *The People Left Behind*, estimated that shifting the differential from 30 to 15 percent would include an additional 700,000 rural people in poverty. Analysis of the 1967 CPS data shows this to be true.

Propensities to Invest in Schooling in the South and Non-South*

Fred Hines

SUBSTANTIAL differences exist between the South[1] and non-South in public schooling expenditures per pupil. One issue of concern is whether the difference arises only from lower income in the South or whether the South also invests less than the non-South in formal schooling out of a given income. Other issues of interest are whether states with a higher proportion of rural or of nonwhite populations have a lower willingness to invest in education, other things equal, and whether federal programs to finance education distribute funds among states progressively or regressively. These issues are examined in this article.

The null hypotheses are that (a) the propensities to invest in formal schooling out of a given income are equal in the South and non-South; (b) racial composition does influence per pupil schooling expenditures; (c) urbanization does not influence per pupil schooling expenditures; and (d) federal assistance to education is distributed regressively; i.e., it rises with state income.

These null hypotheses are tested with multiple regression analysis, using cross-sectional data for the school year 1967–68 from the 48 coterminous states. Current expenditures per pupil in average daily attendance in elementary and secondary schools are used as the level of expenditures for schooling. Per capita personal income in 1967 is used as the measure of the ability to finance elementary and secondary schooling. Schooling expenditures in 1967–68, per capita income in 1967, and data on the percentage of school revenue received from federal, state, and local sources are taken from the *Digest of Educational Statistics, 1968*. Since data on percent nonwhite and percent urban are not readily available for 1967, census data for 1960 are used for these two variables.

Measuring the Level of Schooling Expenditures

Equations (1), (2), and (3) relate the level of current expenditures per student from state and local sources only (Y_1), from federal sources

---

* The author is indebted to J. Martin Redfern and Luther Tweeten for much of the initial thought and work that led to this research effort.

[1] The South consists of those states within the U. S. Census' Southern Region and includes: Delaware, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Tennessee, Alabama, Mississippi, Arkansas, Louisiana, Oklahoma, and Texas.

Fred Hines *is agricultural economist with the Economic Research Service, USDA, stationed at Stillwater, Oklahoma.*

only (Y_2), and from all sources (Y_3) to percent nonwhite (X_1), percent urban (X_2), per capita income in the non-South (X_3), per capita income in the South (X_4), and a dummy variable for New York and Louisiana (X_5). The dummy variable was included for New York and Louisiana because those states appeared to invest substantially more in education than other states, other things being equal. Computed t values are in parenthesis below the coefficients. The double asterisk denotes significance at the .01 level; a single asterisk denotes significance at the .05 level but not at the .01 level. The equations are:

$$(1)\quad Y_1 = 92.47 - \underset{(2.00)^{**}}{2.45(X_1)} + \underset{(.69)}{.59(X_2)} + \underset{(5.26)^{**}}{.15(X_3)} + \underset{(4.71)^{**}}{.14(X_4)} + \underset{(5.18)^{**}}{219.56(X_5)}$$

$$R^2 = .81$$

$$(2)\quad Y_2 = 119.36 - \underset{(.78)}{.23(X_1)} + \underset{(2.11)^{**}}{.44(X_2)} - \underset{(4.69)^{**}}{.032(X_3)} - \underset{(3.85)^{**}}{.028(X_4)} - \underset{(.57)}{5.87(X_5)}$$

$$R^2 = .53$$

$$(3)\quad Y_3 = 211.82 - \underset{(2.08)^{**}}{2.68(X_1)} + \underset{(1.14)}{1.03(X_2)} + \underset{(3.90)^{**}}{.12(X_3)} + \underset{(3.58)^{**}}{.11(X_4)}$$

$$+ \underset{(4.78)^{**}}{213.67(X_5)}$$

$$R^2 = .76$$

Equation (1) shows that: (a) the level of per capita income (indicating the ability to invest in education) is the prime variable in determining the level of state and local schooling expenditures; (b) the insignificant difference between b_3 and b_4 suggests that the responsiveness to an increase in per capita income in the non-South is not significantly greater than in the South; (c) a percentage increase in the nonwhite population, holding other variables constant, has a significant negative effect on the level of schooling expenditures; and (d) increases in urbanization have an insignificant positive effect on the level of schooling expenditures from state and local sources.

The coefficients of equation (2) indicate that federal support for education falls, although insignificantly, as the percentage of nonwhite residents increases; falls significantly as state income increases; and rises significantly as the degree of urbanization increases. The results do not support the hypothesis that federal funds are regressively distributed. In fact, the negative coefficients of the income variables indicate a progressive distribution of federal aid in school financing.

Expenditures per student from local, state, and federal sources are regressed on variables X_1 to X_5 in equation (3). Inclusion of federal with state and local expenditures has a dampening effect, making school expenditures less sensitive to per capita income. On the other hand, federal assistance appears to accentuate the effects of racial composition and rurality. Equation (3) again highlights the overriding importance of income in explaining schooling expenditures. The coefficients of X_3 and X_4 taken literally mean that a $100 increase in per capita income is associated with an $11 increase in per pupil schooling expenditures in the South and $12 in the non-South. However, since the difference in the coefficients of X_3 and X_4 is not statistically significant, we are unable to reject the hypothesis that the propensities to invest in schools are the same in the South and non-South. Thus, the difference in schooling expenditures in 1967–68 in the South and non-South can be largely attributed to the difference in the ability to finance schooling, as indicated by the difference in per capita income.

A comparison of the coefficients of equations (1), (2), and (3) suggests that federal funds for education are progressive with respect to income, percent urban, but are regressive with respect to percent nonwhite. As per capita income increases, state and local funds for education increase significantly and federal funds decrease significantly. As the percent nonwhite increases, state and local funds as well as federal funds tend to diminish. And as the percentage of urban people increase, holding income constant, schooling funds from all sources tend to increase.

Measuring the Public Effort in Financing Schooling

The propensity to invest in schooling, an expression of public support, is measured by the proportion of a state's personal income spent in financing schooling. Equation (4) relates this propensity index based on current elementary and secondary schooling expenditures from all sources (Y_4) to the percent nonwhite (X_1), percent urban (X_2), non-South per capita income (X_3), per capita income in the South (X_4), and the dummy variable for New York and Louisiana (X_5). The equation is:

$$\text{(4)}\quad \begin{array}{l} Y_4 = 8.09 - .021(X_1) + .008(X_2) - .001(X_3) - .001(X_4) + .84(X_5) \\ \qquad\qquad\quad (1.23) \qquad\quad (.64) \qquad\quad (2.61)^{**} \quad\; (2.59)^{**} \quad\; (1.42) \\ \hfill R^2 = .21 \end{array}$$

Equation (4) indicates that in 1967–68 the propensity to invest in schooling (as denoted by the percentage of total personal income spent on elementary and secondary schooling) decreased significantly with higher per capita income levels. Also, the effect of the income level on the propensity to invest in schooling is not different between the South and non-South as indicated by the insignificant difference between the coefficients of the respective income variables in equation (4). Neither the coefficient of the percent urban nor the percent nonwhite variable is statistically significant in equation (4), indicating that when income is held constant these variables have no significant effect on a state's propensity to invest in schooling.

Summary

Results reported herein give no basis to reject the following null hypotheses: (a) that the propensity to invest in schooling is the same in the South and the non-South, and (b) that racial composition does influence per pupil schooling expenditures. However, there is evidence to reject these null hypotheses: (c) that urbanization does not influence per pupil schooling expenditures, and (d) that federal funds for schooling are distributed regressively among states. Although urbanization does not influence schooling expenditures from state and local sources, it does have a significant positive effect on the level of schooling expenditures from federal sources. Addition of federal funds to local and state funds tends to dampen the influence of income on schooling expenditures and results in a more even distribution of expenditures per student among states, according to this analysis.

It is quite true that the southern states spend less than non-southern states on schooling per student. But the difference is explained largely by the relative ability to finance schooling, as measured by income per capita. After adjusting for the ability to invest in education, as indicated by per capita income levels, there is no significant difference between the schooling investment in the South versus the non-South.

A View from the Middle Ground*

O. RICHARD MORRIS

PERHAPS doctoral students have too narrow a view of a doctoral program and the dissertation requirement imposed upon them; hence, they are too often dissatisfied and apathetic. Frequently candidates complain they are unjustly treated relative to the phrase "partial fulfillment of the requirements" appearing on the title page of their dissertations. The platitude, "the best thesis is the one that gets you your degree," reflects an underlying apathy. Others simply regret time spent writing their dissertations. A brief discussion of the rationalist tradition and a theory of knowledge, including how knowledge grows, may help motivate doctoral candidates by providing some understanding of professional scholarship as well as some criteria for making self-evaluations.

The theory of knowledge and description of the rationalist tradition adopted in this paper have been proposed by Sir Karl Popper [1, 2, 3]. Popper suggests that tradition is the intermediary between people and impersonal social institutions [1, p. 134]. He views a tradition as a way to describe "a uniformity of people's attitudes, or a way of behavior, or aims or values, or tastes" [1, p. 133]. The norms, rules, and laws that prohibit people from using unacceptable means to attain their desired goals and objectives in Popper's view of a social institution [3, vol. 1, p. 59].

The rationalist tradition—traceable to the pre-Socratic Ionian school of Thales and Anaximander [1, pp. 136–165]—is recognizable, first, by the critical attitude that perhaps things are not yet perfect; secondly, by their regarding ideas and criticisms separately and irrespective of their proponents; and thirdly, by the generally accepted belief that ideas and criticisms are more fruitfully discussed with a minimum of emotion and passion. But what does a rationalist gain by adhering to such negative attitudes and beliefs?

Popper proposes that knowledge is a product of criticism. "We learn from our mistakes" more than from our successes. By showing that certain

The author chose the term "middle ground," since he is still a graduate student in the "post-prelim thesis stage" of his graduate program at the time of writing. The normative remarks contained in this paper are directed to other graduate students, but our teachers and advisers are welcome to read and comment.

O. RICHARD MORRIS *is a research assistant in agricultural economics at Oregon State University.*

truth is impossible to attain [2], Popper rejects the traditional pursuit of truth and knowledge as proper objectives for science and philosophy [1, pp. 3–30, especially pp. 24–25]. He proposes instead that the task of scholars and scientists be the revelation and elimination of the erroneous and the mistaken solutions to our problems [1, p. 25]. In this sense, Popper's concept of knowledge is quite negative, since we can learn only what is false, but it does not prohibit scholarly progress if we are willing to examine critically the proposed solutions to our problems.

To rational argument and discussion, his theory assigns "the role of criticism of our attempts to solve our problems"; while to our observation, his theory assigns "the equally important role of testing these solutions." Our knowledge progresses by "unjustified (and unjustifiable) anticipations, by guesses, by tentative solutions to our problems"; by what Popper calls "conjectures." "These conjectures are controlled by criticisms; that is, by attempted refutations, which include severely critical tests. . . . Criticism of our conjectures is of decisive importance, since by examining our mistakes and failures we understand the inherent difficulties of our problem" [1, p. vii]. Thus the answer to the preceding question is: A rationalist can learn and he can progress.

From these brief excerpts of Popper's ideas, it is clear that a rationalist tradition is necessary for knowledge to grow. If criticism is absent, mistakes would not be uncovered; hence, there would not be any learning opportunities. Also, criticism is the generator of new problems to solve, which are themselves a necessary input to produce knowledge and a necessary condition for the survival of functioning universities. To minimize sincere and honest criticism would, and does, in effect minimize the opportunities to learn, the growth of knowledge, and the raison d'être of universities.

The preceding discussion provides a framework for proposing criteria to judge a doctoral candidate and his dissertation. The following criteria for the candidate and the criterion for his thesis are consistent with Popper's theory of knowledge and are necessary if the rationalist tradition is to survive fruitfully in a scholarly profession.

Criteria for Candidate

1. The candidate should recognize his and others' mistakes as opportunities to learn.
2. The candidate should be capable of critically analyzing and rationally discussing previous attempts to solve a particular set of problems.
3. The candidate should have a genuine interest in knowledge.

The first two proposed attributes insure that the candidate is critical and can provide worthy opposition to imaginative conjecturing. If a scholarly community contains individuals lacking either of these attributes, "grain-chaff" problems are intensified for the serious scholar. He must spend extra time and resources separating the investigations conducted by other serious scholars (i.e., the grain) from those investigations conducted by those who lack the proposed attribute (chaff). Also, all members of the community need worthy opposition to control imaginative conjecturing and to insure that learning opportunities continue to arise. No benefits accrue to anyone when errors go undetected. These problems and undetected errors not only reduce individual efficiency, but the total efficiency of the community as well. Furthermore, resources must be reallocated to solve these problems and others they may cause.

The third proposed attribute insures that the candidate is serious in his criticism of others and accepts others' criticism with sincerity. In a community where some members neither offer nor accept criticism as an opportunity to learn, criticism may become viewed as retributive or slanderous. Again the serious scholar is faced with the problem of determining whose criticism is petty or sinister and whose is honest and sincere.

The criteria are only suggestions to minimize possible perversion of a rationalist tradition within a profession. It is impossible to completely eliminate all opportunities for perversion because of the uncertainty of future events, and any attempt to do so would be a revival of the Inquisition, which was itself incompatible with bold imaginative conjecturing. A feasible alternative, however, is to impose a requirement that all new members have the proposed attributes. In the uncertain situation of the candidate's final oral examination, the most that his committee can assert by a favorable recommendation is that the evidence does not refute the conjecture that the candidate is qualified.

However, the proposed individual attributes have their limitations and frailties. They should not be viewed as sufficient conditions, but only as necessary conditions for maintaining a strong, fruitful rationalist tradition within the scholarly community. Because of the uncertainties and incompatibilities mentioned above, necessary and sufficient conditions are impossible to propose.

The proposed criteria for doctoral candidates allow certifying a broad range of scholarly talent, yet they make specific lines of demarcation. The criteria permit certifying students who lack imagination to solve problems, but only when they are capable of providing the critical scrutiny needed to control imaginative conjecturing. At the other extreme, certification of imaginative candidates is limited by the criteria to those who realize the importance of criticism and who respect critics and their contributions.

Criterion for Dissertation

The proposed criterion for judging the candidate's thesis is that it should provide corroborating evidence that the candidate possesses the above-mentioned attributes.

The proposed thesis criterion contains no specifications or qualifications for the candidate's conclusions, findings, or reports. A priori conditions on potential findings or conclusions would (1) place the candidate in a situation where compromise of intellectual integrity may be an expedient means of attaining his degree, or (2) require the candidate to conduct several legitimate investigations until he found one satisfying the preconditions. A precondition may be impossible to satisfy if a desired foregone conclusion is, in fact, false. The proposed thesis criterion only reiterates that the candidate's critical capabilities be considered foremost.

However, a major question is still left unanalyzed: What considerations should be made to judge whether the proposed thesis criterion is satisfied? To assess the candidate's appreciation of errors, it is suggested that the various research decisions he made during his thesis investigations be examined to see if he selected analytic methods that are likely to reveal his or others' errors. The dissuasive content of his arguments and comments about present knowledge would indicate the candidate has critical capabilities. Questions to the effect—Do his conceptualizations and comments reveal problems which the present knowledge is incapable of posing or solving?—would provide a rational basis for judging the dissuasiveness of his arguments. The genuineness of a candidate's interest in knowledge would be indicated by the tests he proposes or conducts to empirically criticize and possibly refute his theories. Here the question—Are his theoretical conclusions empirically refutable by observation?—will help in evaluating the proposed tests.

What conclusions or recommendations are suggested by the preceding discussion? First, students' complaints of unjust treatment should be viewed critically by asking the question: Are the students misinterpreting honest and sincere criticism as unjust treatment, or are they receiving unjust treatment in the form of low quality criticism? Second, the platitude that the best thesis is one that gets the student his degree does not really maximize the serious students' own interests. His "best" thesis provides a sheltered opportunity to practice the critical skills he will need if he is to survive and contribute in his chosen profession. Third, from a professional view, the "value" of a doctoral degree is inversely related to the proportion of non-critical persons perverting the rationalist tradition in the corresponding profession. It is to everyone's benefit to maximize the amount of honest, sincere criticism he is capable of providing, and to maximize the total amount of legitimate criticism communicated among the members of a profession.

At a Crossroad: Graduate Teaching in Agricultural Economics*

Curtis F. Lard and J. Rod Martin

TEACHING must be considered the most important function of a university regardless of whether it is at the undergraduate or graduate level. Therefore, the most important task of the university professor is teaching. The primary emphasis of this presentation is placed on graduate teaching in agricultural economics. The definition of graduate teaching, as used in this article, includes such functions as: formal classroom teaching; informal teaching or intellectual discussions; conducting seminars; program, thesis, and research directing; and professional and personal counseling. We believe that the various departments are not giving enough attention to graduate teaching and that this is a major problem facing the profession.

The Problem

An appropriate framework for delineating the problem of graduate teaching could take the form of a hypothesis. *Graduate teaching in agricultural economics departments just happens without much planning and preparation on the part of the graduate teacher and with inadequate coordination and supervision within the departments.* We do not intend to empirically test this hypothesis in this presentation. However, a review of our professional journal indicates that many agricultural economists have been concerned about undergraduate teaching [4, 8, 9], and the graduate training of foreign students [1, 5]. The number of articles occurring in this Journal over the past 10 years is evidence of this emphasis. However, very little space has been devoted to graduate teaching in general. One could conclude from this that graduate teaching in agricultural economics is in a good state of affairs, or one might conclude that it is in such a condition that we should not mention it or else we do not care.

We cannot accept any of the above conclusions. But observation of graduate students and graduate professors in the discipline of agricultural economics indicates that we are facing some major decisions in graduate teaching. Many professors view teaching as a necessary evil to which they want to give as little time and effort as it is possible to "get by with." In addition to this, the complexity of problems in modern agriculture, the pursuit of truth, and the dissemination of information are beyond the

scope of an individual professor and must be approached through an interdisciplinary or systems orientation. This is just as relevant for graduate teaching as it is for research, which was emphasized by Shaffer [7]. This leads us to believe that graduate teaching in agricultural economics is in a critical state and *at a crossroad.*

Assessment of Good Graduate Teaching

Schultz [6] has indicated that he believes it is possible for us to apply our concept of efficiency and our analytical thinking in assessing teaching and learning. Let us assume that we can assess or evaluate our graduate teaching. From the standpoint of the department, how should this be done?

In assessing graduate teaching we must look closely at the component parts—the objective, resources, and alternatives [2]. The resources consist of the university, the academic community, the department, supporting departments, professors, graduate students, and the facilities. First, the university and the academic community must provide an environment and an atmosphere in which learning can take place. This would include such things as an adequate library, computer facilities, a concerned administration, and freedom of inquiry.

The department must provide the professors, the physical facilities, the course offerings and programs, and an intellectual environment conducive to learning. For an agricultural economics department to have an excellent graduate teaching program, its supporting departments, such as economics and statistics, must have strong programs. An obvious and essential requirement is that the departmental administration must recognize and reward good quality or excellent graduate teaching.

With respect to the professor-student relationships, the professors who teach graduate courses and advise graduate students should be viewed as learning partners with graduate students. For maximum learning and development to occur, this partnership must prevail throughout the graduate student's program. There is a tendency to equate success with the fact that students receive Ph.D's and professors advance in their profession. But this does not mean that good graduate teaching has occurred. Although there are many excellent graduate professors in this discipline, we must be aware of the fact that there are superior substitutes for almost any professor and perfect substitutes for many professors in graduate teaching programs. Proof of this is evident by the fact that several leading institutions have utilized programmed materials and computer instructions to increase effectiveness and even replace some of the teaching functions of the professors. Based upon these experiences, many see the computer as a liberator of the teacher, enabling him to spend more time on the specific needs of the student [3].

In considering the effectiveness of the teaching-learning process in our agricultural economics departments, we must take the following items into account: (1) a continuous evaluation of the total framework utilized within a department to prepare individual students to respond favorably and solve various problems that they encounter as students and as future professional agricultural economists; (2) tests to measure the increased ability of the students to use principles and techniques in problem solving situations; (3) the relative emphasis placed on specifics as contrasted with principles and theories in graduate teaching; (4) the general relationship that prevails between the student and the professor; (5) continuous evaluation of graduate professors through some well-constructed means of evaluation; and (6) reviews of course content and research projects conducted by graduate professors. We believe that these assessments may be initiated and/or conducted by an appropriate group within each department and used by the department for the betterment of all parties involved.

A Recommendation for Improving Graduate Teaching

The major point of our recommendation for improving graduate teaching is the establishment of a graduate teaching faculty within each department. This faculty would assume the responsibility of coordinating all graduate teaching activities within the department. Establishing a graduate teaching faculty would initiate immediate action with respect to pulling together all of the loose ends that may exist in the graduate teaching program. Currently, in many departments one individual or an individual for each major field of study usually spends a major portion of his time coordinating graduate functions. This department member should probably continue in this capacity for the incoming students, but he should report to and be guided by the graduate teaching faculty.

The specific duties of the faculty could be divided into two distinct areas: (1) the current graduate program and (2) the long-run program. In improving the current program the faculty should encourage the administration of and work out specific details for the following:

1. Closer correlation of research and teaching so that ideas generated in teaching can be further developed by students and/or faculty, thereby enhancing both functions.
2. Use of a comprehensive Ph.D. examination for those students who aspire to graduate teaching or a broad examination for new teachers.
3. The employment of superior teaching techniques and/or aids, such as visual aids, computers, team teaching, and special lecturers to help lower the cost of learning or increase the value of new knowledge to the students.
4. Train teachers and students to recognize the "threshold of learning"

or "the take-off stage for learning" and to stress only the most significant concepts and techniques.

5. Replace some semester courses that are too long for sustained high rates of learning with four-week periods of concentrated study on only one or two courses concurrently.

6. Put the philosophy base back into our Ph.D. programs in agricultural economics, especially training in reasoning and the philosophy of the social sciences.

7. Give doctoral candidates who plan to teach some actual teaching experiences under the supervision of outstanding graduate professors while they are in graduate school or when they first start graduate teaching.

8. Employ in-service training programs for the teaching faculty.

9. A comprehensive evaluation of graduate teachers by examining their teaching, courses, research projects, student counseling, writings, and a periodic re-examination to determine if the professor "measures up" or is obsolete.

10. Equal compensation for good quality graduate teaching and for good (published) research.

Although not as clear cut as the immediate needs, the responsibility of the teaching faculty regarding the long-run program might be even more important than the short-run or current activities. This is particularly true with respect to the matter of developing and maintaining *leading* departments. One obvious area that should receive attention is developing computer-assisted, computer-managed instruction and programmed materials to be used in the agricultural economics departments. The future use of these techniques is inevitable as a result of their effectiveness. An individual professor cannot be as effective as a team of experts because we can be assured that students will be exposed to a "core" of theory and problem solving techniques when programmed or computerized courses are developed by a qualified team from the graduate teaching faculty. This approach may also be the best way to develop an individual's learning and problem solving ability. The "liberated" professors may have more time for research activities which would update their teaching. The importance of this area is such that each department should allocate one qualified staff member, full time, to the study and utilization of these new teaching techniques. This staff member would work closely with and report to the graduate teaching faculty.

Establishing graduate teaching faculties to administer teaching functions could be the most effective way of upgrading graduate teaching in agricultural economics. Most departments have the collective ability in terms of teaching staff to develop excellent programs. The faculty could be effective in terms of coordinating, assessing, and improving their own activities. By its very existence, the faculty would have influence on the department chairman and the dean. But the most important aspect is that in the administration of the best possible program, the graduate teachers would have to face up to their real responsibilities!

In concluding, we challenge the American Agricultural Economics Association to develop an award program for graduate teaching in agricultural economics comparable to the current undergraduate teaching award.

Institution Building: Training Gap in Economic and Agricultural Development*

HAROLD D. GUITHER

TECHNICAL and development assistance programs of the U.S. government, private foundations, and universities have operated on the premise that "the most effective and enduring contribution to human resource development is through the building of indigenous educational institutions which will enable a nation to help itself by educating its own people to enter and sustain themselves in the modern world" [5].

Study and training for foreign participants have been financed by the USAID, AID-university contracts, private foundations, and home governments. Although U.S. training is considered a means to develop subject matter competence, many do not teach or carry on research when they return home. A survey report of AID participants stated, "One can discern a net loss from the ranks of professionals and subprofessionals and a net gain in the administrative and managerial categories" [3, p. 158]. A returned student needs additional tools or capabilities to lead and administer a new or remodeled institution to further his country's development. However, only a few agricultural economists have pointed out the need for training in administrative principles and practices [4, 6].

Many goals of developing nations can often be achieved only through an organized institution [2]. A study of rural development assistance contracts concluded, "Training in leadership and administration should be an integral part of many participant programs and AID and the universities should develop cooperatively concentrated post-degree short courses to meet this need" [1, p. 21].

Areas of Training

Areas of training for leaders and administrators in agricultural institutions are listed below. Although this discussion of institution building emphasizes educational institutions such as universities with teaching, research, and extension programs, the same concepts and principles could also apply to other institutions engaged in credit, marketing, information, planning, or cooperative activities.

---

* The author wishes to acknowledge the helpful comments of W. D. Buddemeier and W. N. Thompson, who read an earlier draft of this paper.

HAROLD D. GUITHER *is associate professor of agricultural economics at the University of Illinois.*

Historical perspective and concepts

The agricultural institutions of developed countries offer ideas and motivations for those from developing countries. Changes, however, should fit local cultural, economic, social and political values. Study should include: the concept of institution building and relationships to agricultural and economic development; the application of institution building to the stages of a country's development; the purpose of national planning bodies and the role of agricultural institutions to facilitate development; and the relationship of national agricultural and economic policies to the developing institutions.

Organization, administration, and policy development

Study and training should include: administering the academic program, library, research station, and extension programs; maintaining physical facilities; identifying and applying appropriate and effective communication methods; using science and research to implement development, rather than treating it as an end in itself; developing new alignments between scientific disciplines to improve research, teaching, and extension; using sound business management in accounting, purchasing inputs and supplies, marketing surplus products, merchandising the capabilities of graduates; and using capital and credit to facilitate institutional development.

Personnel management

For those in responsible positions, the following should be included in a study and training program: improving administrative competence through visiting consultants, outside study by staff members, and short overseas observation visits by top administrators; orienting staff members for service and motivating them to generate public support; developing attitudes and philosophy to generate productive research and teaching programs; facilitating student achievement consistent with institutional goals; developing professional and personal attitudes among faculty scientists that contribute to success of the institution as well as prestige to the individual; developing meaningful and constructive relationships between students and faculty; sharing authority for professional decision making among faculty members and building faculty morale by clear understanding of personnel policies, appropriate working conditions, and consultation on changes of assignments.

Relationships with outside groups and agencies

Maintaining communications linkages between the governing elite and the community will permit the institution to carry out its objectives and receive continuing support. Training and study in this area should include: developing community teamwork and enlisting cooperation from outside groups; adapting the mechanisms for gaining support to the culture and environment of the developing country; developing insights into the role that farmers and local people can play as advisers and assistants in gaining public support; finding ways to use developmental assistance offered by foreign agencies, governments and international organizations in ways that will benefit the institution and meet the purposes for which such aid is offered; and taking an appropriate role as administrators in working with local government and assistance agency representatives to achieve productive returns to the developing institution.

The Role of Agricultural Economists

Rural social scientists, including agricultural economists, can play a key role in leading research and training in agricultural institution building and administration. By their training and experience they have an understanding of (1) institutions contributing to economic development; (2) principles of resource allocation to achieve optimum output; (3) efficient labor and capital use; (4) the role of borrowed capital (credit) in economic growth; and (5) the principles for efficient operation of the firm.

The agricultural economist should recognize his limitations in understanding cultural differences and sociological motivations that may overshadow economic incentives. Colleagues in public and business administration, sociology, political science, and anthropology could also contribute in the subject matter areas outlined above.

Program Alternatives

The setting for disseminating ideas on institution building could be (1) regular university courses offered for graduate credit; (2) seminars for credit or non-credit for all agricultural students from less developed countries; (3) special seminars or short courses which could be given after completion of graduate degrees just before the student returns to his home country; (4) seminars or short courses for new administrators or key leaders given either in the United States or overseas.

If some who participate in such study programs continue as teachers or research workers instead of moving into administration, their knowledge and understanding should enable them to contribute more effectively to their institution's development. If economic and agricultural development is largely human and institutional development, developing people for leadership deserves at least equal priority with developing land, buildings, crops, and livestock.

Involvement in Undergraduate Education

MURRAY H. HAWKINS

STUDENT disinterest and teacher apathy are threatening to turn academic activity at the undergraduate level into a frustrating and meaningless experience. The professional nature of agricultural economics has tended to blunt this development, but agriculturists cannot become complacent nor deny the possibility of its imminent arrival. The striving for excellence and the increasing prestige in graduate education and research (in conjunction with the role of the agricultural economist as a consultant) have hastened the downgrading of undergraduate teaching as a vocation, and larger academic classes tend to reinforce the situation.

Student Awareness

Students instinctively recognize the growing preoccupation and indifference of some of their professors and the consequent mediocrity of instruction at the undergraduate level. The bright student looks eagerly forward to graduate school where he will finally be allowed to do his thing. The average student "kills time" until that great day when he can enter the "real" world. The below average student drifts in a state of stultified helplessness, unstimulated and unloved. More and more frequently, inquiring minds break out of this situation and vigorously protest their abandonment.

These statements are not a revelation; indeed, these reflections even cross the desks of university administrators from time to time. Yearly statements are dutifully issued to the faculty that undergraduate teaching is the primary role of the academic community. After conventional lip service has been paid to the ideal, the statements are carefully and firmly set aside at the first possibility. Staff promotion, appointments, tenure considerations, and other aspects of academic life are then evaluated on the more traditional basis.

The task

What can be done? The goal of the institution should be to totally involve the *entire* academic staff, auxiliary staff, and the undergraduate students in the learning process.

The assumption

One must assume that staff, students, and administrators are willing

---

MURRAY H. HAWKINS *is associate professor of agricultural economics at the University of Alberta.*

and able to involve themselves and that they have the means for doing so.[1]

The Technique of Involvement

There is no perfect solution. The techniques suggested here have been used with varying degrees of success by the author and his colleagues. Nor does this list of methods under discussion exhaust the possibilities.

The undergraduate course structure and curriculum needs reshaping with concern and ingenuity. Stereotype lectures, exams, and uninspired grading systems must give way to new approaches. Reforming and enriching the undergraduate program should assume first priority in the hierarchy of academic and quasi-academic endeavours. An attitude of total commitment should prevail in departments teaching undergraduates. Given an environment in which undergraduate instruction takes priority and in which undergraduate teaching assignments are given to staff members able to communicate with their students, it will be possible for the lecturer to begin the task of mutal involvement.

A Two-Course Core[2]

The subject matter for a core subject area in agricultural economics should be divided into at least two component parts. Typically, this division will involve two quarter or semester courses. Care must be taken in the initial course to adequately prepare the student for his adventure into in-depth participation in the second.[3]

Component one

The first component course should be of a theoretical nature and should prepare the student to plunge into the second course. This arbitrary course division would also allow non-specialists to participate at the lower course level. The procedure is somewhat like preparation in traditional undergraduate education for graduate school and differs only in that its application may occur at the second, third, or fourth year of the university program, its implementation depending on the level of prerequisites and general background material.

The first course should concern itself with an intensive lecture and reading program. However, this approach is not as traditional as it would first appear. The first requirement of this course, or for that matter any course, should be to prepare a detailed and specific course outline. The outline should include such matters as course content, general course policy outlines, grading procedures, weekly reading assignments, selected supplementary readings, quiz and midterm dates, office hours,[4] term papers, and miscellaneous course assignments. The outline should be distributed on the first day of class. It becomes, in effect, an unofficial contract between the class and the instructor. It provides a proposed plan of operation for the course that will prove invaluable in control and evaluation proceedings. In addition, the students will have a firm foundation from which to operate and (to a limited extent) from which to bargain. All course outlines should be filed with the department chairman and interested contemporaries.

---

[1] Perhaps this assumption is unwise, but most economists succeed in eliminating the real problems with a selection of assumptions.

[2] The core area, within the author's area of experience, includes marketing and agribusiness management.

[3] In addition to the first course listed herein, all necessary mathematics, statistics, etc. courses should have been taken.

The reading list for undergraduates should be realistic in length and depth. Detailed and prolonged reading assignments that are developed to illustrate how "high powered" a course is, succeed only in discouraging the class and dampening the enthusiasm norm of the students. The selection of a good text plus the addition of two or three well chosen supplemental readings should prove adequate. An additional bibliography may be interesting for some students and should also be provided. In an era in which undergraduate curricula are being comprehensively overhauled, it is essential to be realistic in regard to the total number of hours available to any one course. A well chosen, short, and intensive reading list upon which the student is examined in depth would do much to reduce the credibility gap between the instructor and the students.

In larger classes or at the lecturer's discretion, class representatives should be elected to provide feedback and consultation on the course presentation and to provide suggestions for the 25 to 30 percent of the course content that would be under student advisement. In an introductory three-lectures-per-week course, two lectures should be directly the sole responsibility of the instructor. The final lecture should concern itself within the relevant subject area but should involve some additional material on subjects excluded in the course or a deeper analysis of course materials of general interest to the class. Special speakers, interested students, or the instructor himself could offer the third lecture.

Student protest has almost eliminated the "snap quiz" and irrelevant term paper. Realistically, one should not regret their demise. However, the substitution of a number of short, concise, prearranged quizzes is an excellent technique for involving the student in the course material. The use of this evaluation technique allows the elimination of the lowest quiz grade from the final tally. It is extremely difficult to be prepared for all efforts, and students note the inherent justice of this procedure. Term papers, with the growth of excellent student libraries and their collection of source materials, are becoming a less useful device in the learning process. They are difficult to evaluate, and outright plagiarism is becoming increasingly prevalent. If term papers are to be used, there is a need for ingenuity and variety of design in order to "action orientate" the material. A comprehensive, objective student evaluation should complete the first course.

---

[4] An open door policy during the school term should be department policy. It is recognized that large classes and abuses of the policy may limit the universal application of this principle. However, consulting and extracurricular affairs should not impose office hours.

Component two

The second course in the two-course undergraduate presentation should be a "mini" version of graduate school. It should evolve around a balanced attack on the perception of the student and his total involvement in the subject matter.

In several areas of agricultural economics, computer games could form the basis of the course. In addition, selected case studies, field trips, debates, oral and written team presentations, and visual aids could supplement this approach. The above approaches can be abused, but properly used, they can have a considerable impact in involvement. Several recent developments are also worth mentioning. Through the use of television and video tape, class projects take on a new dimension. For example, preparation of a half-hour television presentation on an approved topic stimulates the undergraduate to give his time and interest to the project and involves him completely. Moreover, screening of the final product is a worthwhile experience for the entire class.

As a matter of policy, agricultural economics departments should develop research projects that utilize the considerable talents of their undergraduates. Supervision of their endeavours and indeed the development of the working program could be the responsibility of selected graduate students, the goal of the "mini" research experience being to involve the professor, graduate student, and undergraduate student in a coordinated effort.

Through the use of the grading system, student participation can be broadened even further. At an early stage in their careers, students should be contemporaries. Provided that preparation in the first phase of the two-course program has been adequate and that detailed grading guidelines are available, the lecturer should have few qualms in regard to sharing this onerous task.

It becomes necessary at this point to reinforce a previous point. Unless the student has been prepared adequately at an earlier stage in the educational process, the implementation of the involvement techniques will have many of the characteristics of a "mixed orgy."

General Observations and Conclusions

The challenge of maintaining a meaningful relationship between the student and his teacher has become an increasingly difficult task. Motivation becomes an intuitive feeling that can be developed only through joint involvement. Incentives to learn must be delicately integrated throughout the curriculum. Agricultural economists have stressed that bountiful production depends on the wise use of incentives in order to direct and stimulate individual entrepreneurs. The lesson has been learned well in the general policy area but not at the undergraduate teaching level. Implementation of an impersonal grading curve has effectively dampened the grade incentive in the undergraduate program. Classes are quick to establish a "bogey" or norm, and instructors are forced to live with this informal climate.

This text has attempted to outline an argument to revitalize the undergraduate teaching and learning experience. The revitalization goal will become a reality only when the academic staff, the administration, and the students develop a deep feeling of commitment and mutual involvement.

Using Local Comprehensive Planning to Control Lakewater Pollution in Seasonal Home Communities[*]

ROBERT W. SNYDER

A GROWING body of research indicates the rising economic importance of preventing lakewater pollution in second home communities. Estimated annual local cottage-user expenditures of $1,800 per unit influence many local government decisions that sharply affect summer home growth potential [3]. Lakewater pollution and over-eutrophycation resulting from lakeshore use must be controlled. How much is this going to cost and how will the total cost be allocated? What is the role of local comprehensive planning and zoning in determining answers to these questions?

Clearly, the value of comprehensive planning varies with the source of pollution. Where pollution results from aggregations of people, farming operations or industrial activity, pollution control costs should be assumed by each polluter. These costs will not affect most location decisions since they usually cannot be avoided by locating elsewhere. Each violation or potential violation warrants individual attention. Such customary preventive devices as code enforcement, regulation, inspection, and licensing can be economical and successful. Action by a state agency, if adequately financed, may be quite appropriate. Local comprehensive planning will have, at most, a relatively minor role.

Pollution traced to lakeshore residential property presents a different situation. Presumably, the incidence of cost still should rest largely on the polluter, i.e. the resident or the seasonal homeowner. But the amount of cost can be sharply affected by comprehensive planning. Lower costs will attract potential vacation home buyers. Thus, comprehensive planning can contribute to economic development.

Comprehensive planning operates well only in a dynamic setting. Seasonal home communities are growing rapidly. Nationwide, the decade of the fifties saw a 74 percent rise in census-enumerated second homes to a

1960 total of 1,400,000 [4]. Casual observation and other indicators suggest that the trend has continued, probably accelerating, in the sixties. In Minnesota, an estimated additional 4,000 lakeshore cottages appear annually. This high growth rate has led to predictions of the incipient disappearance of available undeveloped lake frontage. Assuming a density equivalent of one hundred feet per cottage, however, if present trends continue, Minnesota's natural endowment is such that less than one-half of the total frontage is likely to be developed by 1980. As a result of rising interest in non-frontage property, even this projection may be on the high side. Ragatz has predicted that future second homes will increasingly be located in complete "planned unit developments" (PUDs) in which a limited amount of lake frontage is shared among several non-frontage cottages [2]. Other shared facilities may include golf courses, swimming pools, tennis courts, and so forth. Several PUDs have already appeared in Minnesota, as elsewhere. They are strongly competitive with cottages on individual frontage lots and will become more so as the price of frontage continues upward. This will retard the development of frontage property.

Given these facts, unless the Minnesota case is atypical, the continuation of present trends will produce a development pattern around many lakes comprising numerous separated dwellings or small clusters of dwellings, a few PUD's, some commercial recreation establishments, and public accommodations. Under these low density arrangements, probably persisting for some time, the only economically feasible way to dispose of household wastes is private on-site disposal systems. Locally controlled boards, strenuously enforcing adequate sanitation codes, can prevent lake water pollution. Comprehensive planning can contribute by identifying areas where problems are likely to occur, establishing appropriate physical development standards and providing guidelines for code formulation. To a very limited extent, "use" zoning may prevent development at some of the poorest locations.

This method for pollution control has the advantage of minimum interference with the property rights of individuals. It has the disadvantage of high cost. Inspecting and regulating large numbers of individual disposal systems will be both costly and difficult for local government. Homeowners, especially those with cabins on so-called "tight" soils or high water tables will also face high costs. If and when private disposal systems need to be replaced with a public system, homeowner costs essentially double. Many areas are well on the way through a process that will result in this multiple expense.

The alternative to on-site systems, code enforcement, and the ultimate high cost is to use comprehensive planning in a somewhat bolder context. This would require local government to exercise a significantly higher level of control over the pattern of development. Enforced orderly development could be served by public waste disposal systems from the start. These public systems, using modern technology, often are cheaper and more efficient than private systems. The lagoon system, in particular, appears to be particularly adapted to situations where disposal problems are concentrated in the summer months. Properly planned, waste collection and treatment facilities could be enlarged without excessive additional cost. Development of areas with tight soils and high water tables would not create unusual problems.

Savings on many other public services, such as roads, law enforcement, public water, and even street lights are also possible with controlled, orderly development. Reducing public service costs is important. Minnesota research results suggest that township governments in lakeshore areas lack the financial means for providing adequate access roads for all lakeshore property. Meanwhile, survey responses indicate that seasonal homeowners are highly critical of local access roads, which in Minnesota are provided by town governments.

Can Comprehensive Planning Reduce Costs?

It is common knowledge that supplying public services to a scattered residential development results in a high per unit cost. The frequently heard "pitch" of comprehensive planners operating in suburban areas keeps this fact safe from oblivion. The planners, however, also tell us that we can control development patterns through comprehensive planning. This has not, so far, proven to be a statement of very great validity. Our experience in trying to prevent urban sprawl and leapfrog residential development has said loudly and clearly that we are losing the battle. As unpalatable as it may be, the truth is that zoning and other land-use control devices, although beneficial in other ways, have been strikingly ineffective in controlling sprawl. This has been due to three basic facts of life:

1. Holders of undeveloped land, sometimes unwisely, prefer playing the game of "real estate roulette" to the unspeculative security offered by orderly developments.
2. Local government decisions regarding zoning and related matters are strongly influenced by the preferences of these landowners.
3. We have a long tradition of strong property rights and are reluctant, even where political influence is not a factor, to take away the privilege of playing "real estate roulette" under a control system that pays the landowner nothing for giving up this right.

Besides, the easily visible effects of this failure of zoning and the lack of sufficiently stringent zoning regulations, we learn from Manvel that three-fourths of all requests for zoning variances and rezoning have been approved, despite the wholly justified complaint of planners that such actions eventually destroy a large part of the value of comprehensive planning [1]. Thus, more stringent regulations may not make zoning more effective.

There is little reason to think zoning will be any more successful in rural lakes regions than in the suburbs. More likely, it will be less successful. The level of ignorance about the physical characteristics of our lakes and lakeshores is distressingly high. Until we are willing to spend large sums to dispel this ignorance, we will not be in a position to use zoning intelligently even for the limited purpose of augmenting sanitary code enforcement. The level of expenditures required to produce knowledge needed for more stringent and detailed zoning may not be acceptable.

Recognition of the problem is a first step, but an encouraging one. We are gradually learning more about our natural resources. Future zoning ordinances will reflect this greater knowledge as well as more experience with lakeshore zoning. But zoning is, and probably always will be, an imperfect tool. Where lakeshore development control is essential other more effective measures will have to be taken.

One such device is simply to install public sewerage in desirable development areas prior to actual development. Initial costs are high, with estimates running up to and beyond $20 per foot of frontage. They would probably need to be covered temporarily by issuing general revenue bonds, with eventual recovery from assessments against property being developed. Long-run savings should be substantial, particularly if sewerage installation is accompanied by other public investments such as improved roads. Such development guiding improvements might be financed in the same manner as sewerage.

Another process is the purchase of lakeshore property by a public body, installation of public sewerage, roads, etc., and reversion to private ownership. Deed restrictions as well as zoning controls, can be imposed. This device, very similar to urban renewal, would not face many problems, such as relocation, that trouble downtown renewal projects. Many modifications are possible. One option is to purchase "development rights" rather than a fee simple estate in lakeshore property. These development rights, long advocated as a development controlling device, would be returned to private ownership when development is considered desirable.

Alternatives for controlling lakeshore development and containing the cost of controlling pollution are many. With the growing economic importance of second homes in many rural lakes regions and the advantage of low cost pollution control in attracting the seasonal homeowner, steps must be taken soon, else the pace of lakeshore development will erase the significant economic contribution that could be made by comprehensive planning.

The Cost of Food Aid to Recipient Countries*

GARY L. SEEVERS

SINCE the passage of Public Law 480 in 1954, there have been two major trends in United States food aid policies. The first has been a gradual transition from the disposal of surplus agricultural commodities to a program emphasizing economic development in recipient countries [1]. The self-help criteria specified in the Food for Peace Act of 1966 high-lighted this redirection [6, Sec. 109]. The second and parallel trend has been a gradual hardening of terms, so that shipments have become more like commercial sales. As a result of the latter trend, recipient countries are facing higher payment burdens. In this paper I endeavor to show how the shift to credit sales in the 1966 Act contributes to the commercialization trend and how by raising the cost of food aid, this policy conflicts with the economic development trend.

Historical Costs

For comparison, Table 1 shows estimates of the costs associated with shipments through 1966 for the four major programs. The total export value of shipments was $15.7 billion, of which 64.9 percent were foreign currency sales, 17.4 percent were emergency relief and donations, and 14.1 percent were barter transactions. The legislation was amended in 1959 to permit long-term credit sales; shipments under this program began in 1961 but constituted only 3.6 percent of the total through 1966. From the viewpoint of recipient countries, each program resulted in somewhat different costs. For present purposes, I will assume that barter sales were equivalent to cash sales, because recipient countries exchanged materials for the farm commodities, and that donations and emergency relief were gifts. The two remaining programs—foreign currency and credit sales—become the primary focus of subsequent discussion.

The payment burden for foreign currency sales can be estimated in a variety of ways, but in principle it is given by the proportion of the foreign currency payments that the United States spends in the recipient country. This assumes that expenditures command resources for purposes beneficial to the United States, and that foreign currencies spent measure the opportunity cost of resources.[1] The allocations for United States ex-

[1] Cost estimates are based on the *allocation* of foreign currency receipts for "U. S. Uses," rather than actual expenditures. Several difficulties arise in applying allocations

GARY L. SEEVERS *is assistant professor of agricultural economics at Oregon State University.*

of all foreign currency sales to a credit basis by 1972 constitutes a significant policy shift. In light of this new legislation, the question arises as to how the new credit policy will affect the payment burden. One way to estimate the burden that has been employed in the foreign assistance literature is to apply conventional discounting theory to the flow of dollar repayments [2, pp. 71–74]. This procedure yields an estimate of the real burden of a foreign assistance loan as a percentage of the loan's nominal value. The lower the interest rate charged on a loan, and the longer the grace period, if any, over which no repayments are required, the smaller will be the real burden and, therefore, the larger the grant element of the loan.

Under the 1966 Act, the maximum repayment period is 20 years at 2.5 percent interest, with a two-year grace period during which one percent interest is charged. Assuming that the loan is repaid in equal annual installments after the two-year grace period, the real burden depends only on the appropriate discount rate. When discounted at rates ranging from 5.75 to 15 percent, the corresponding discounted costs vary from 71.7 to 35.7 percent of the nominal value of the food aid. At a 10 percent discount rate, the cost would be 50.6 percent, which is about double the cost of past foreign currency sales.

The 1966 Act permits certain countries to shift to what is called "convertible local currency credit" (CLCC) sales. Under this option, the United States has the privilege of asking for payment either in dollars or other hard currencies, or in the country's currency to the extent needed for U. S expenditures in the country. While payment in any of these currencies is equivalent to the payment required in dollar credit sales, the princpal advantage for the recipient country is that the terms permitted for CLCC sales correspond to the long term U. S. foreign assistance loans —40 years at 2.5 percent interest, with a 10-year grace period. Under these more lenient terms, the cost of a loan, discounted at 10 percent, would be only 24.9 percent. This is only marginally higher than the cost of foreign currency sales. Consequently, countries that are allowed to convert to CLCC rather than dollar credit will experience a much smaller payment burden.[2]

Other policy changes that reflect a rising cost to recipient countries could be detailed.[3] For instance, since 1964, recipient countries have been required to pay the total ocean freight charges, excluding the difference between the U. S. and foreign flag vessel rates, on the 50 percent that tation, are described and compared to the results of partial analysis of the same area.

---

[2] Countries qualify for conversion to CLCC on the basis of their external financial position—foreign exchange reserves balance of payments, and debt service capacity.

[3] On July 29, 1968, the legislation was extended through 1970. In order to improve the U. S. balance of payments, the terms were hardened somewhat further by requiring immediate payment for a portion of credit sales and allowing greater U. S. discretion in spending foreign currencies [7, p. 11].

Pinal County, Arizona, about 85 percent of whose agricultural economy is based on groundwater, was chosen for a case study. This county accounts for about 21 percent of irrigated crop acreage in Arizona, but nearly half of its "water problem" in terms of groundwater level decline. The economic model is derived from the work of Stults. Data on resource organization, production technology, and costs and returns were based on a random sample accounting for 30 percent of all farms over 25 acres in size and 38 percent of all field crop acreage in the county. (Vegetable and citrus crops account for only four percent of irrigated crop acreage in the county. Since water represents only a small proportion of production costs for these specialty crops, their demand and the negligible amounts used for nonirrigation purposes were treated as exogenous requirements in the model.)

The Integrated Model

The need for brevity calls for a rather concise description of the procedure. Operation of the model begins by specifying the initial conditions affecting farmer decisions in period *t*. These are, for each farm size in each subarea: (1) the net return over variable costs for each potential use for irrigation water; (2) the depths to water, and thus the costs of water, in the various subareas of the study area; and (3) the constraints on land and water availability.

These conditions become the parameters of linear programming models of representative farms of the area. There are four farm sizes for each of six subareas. Solution of the 24 programming models gives the cropping patterns that would maximize net income for the individual farmers of the area, given the opportunities and constraints they face with their environment and the groundwater management policy under examination. In addition, the quantity of pumped water demanded under these conditions is determined for each subarea for the given time period.

These quantities of pumped water become the inputs into the electric-analog model of the aquifer.

> An electric-analog model is an electric system that is analogous to the groundwater system. Resistors simulate the ability of the sediments to transmit water, and capacitors simulate the storage of water within the soil pores. The response of the model to the simulated pumping stress is shown on an oscilloscope in the form of a hydrograph. Thus, the oscilloscope acts as a water-stage recorder, which continually measures the water level in an observation well. By measuring with the oscilloscope at different points, it is possible to prepare a contour map of water level changes caused by a specific stress applied for any specific length of time [1].

After computing the average change in depth to water over each subarea, new constraints in terms of maximum pumping capacities by depth to water and subareas are developed for the beginning of time $t + 1$. Because pumpage depths have changed, the costs of water to be entered into the new linear programming models are changed as well.

Several other adjustments in the parameters of the water demand model are made at this time. In each year, a certain number of the wells in the area reach the end of their useful life. A decision must be made between replacing the well or abandoning a portion of irrigated acreage. Well replacement requires a large fixed investment, which must be amortized over the coming years. Well abandonment means sacrificing the expected net return from the crops that could no longer be grown. Crops that would be sacrificed are the *marginal*, low-valued crops such as barley and alfalfa, not the high-valued crops such as cotton or vegetables. Because large farms are more efficient than small farms, large farms can better afford well replacement.

Comparison of the cost of replacing the wells with the discounted stream of expected net returns of potential crops to be irrigated is made for each size of farm. If the smaller farms cannot afford to replace a well but the largest farms can, the acreage that the smaller farmers would have had to sacrifice is assumed to be purchased by the large farmers and the well is replaced. Thus, land is not abandoned because of lack of water until the largest, most efficient units can no longer afford the water cost. Because the larger farms use different production technologies than small farms and have certain other advantages such as purchasing efficiencies, the procedure of projecting changed farm size over time provides a dynamic character to the model.

With the constraints of the linear programming water demand model adjusted to the new conditions, the model is solved for the period $t + 1$. This cycle of calculations is repeated until the end of the planning horizon is reached. Because of the large number of computations required for each time period, projections were made for ten-year intervals rather than annually.

Empirical Results for Pinal County

Table 1 presents the agricultural projections for Pinal County for the years 1966 to 2006. For 1966 through 1968, the actual reported acreages planted are given to illustrate the predictive ability of the model.

The model was constructed in terms of the cotton program in effect in 1966, which had a lower allotment than in 1965. In 1966, the upland cotton allotment was cut to 84,000 acres. Our projections for 1966 overestimated total cropped acres because, while in the model all readjustment occurred instantly, farmers actually take some time to adjust to a new equilibrium. The 1966 projections are thought of as representative of the period 1966–1976. By 1968, readjustment is close to that projected. Alfalfa is adjusting downward, grain sorghum upward, and barley, wheat, and miscellaneous field crops are equal to the projection. Since the 1968 cotton allotment was raised above the constraints dictated by the 1966 program, upland cotton acreage in 1968 was higher than projected. It is doubtful that allotments can remain this high over time, however. Downward adjustments in the cotton allotment would be reflected by increased grain sorghum acres. We submit that the model closely reflects actual farm adjustments.

Table 1. Acreage of field crops, net revenue over variable costs and water use, Pinal County, 1966–2006[a]

Year	American-Egyptian cotton	Upland cotton	Grain sorghum	Alfalfa	Barley, wheat, and other[b]	Total cropped acres	Water use	Net Revenue over variable costs
	thousand acres						thousand acre-feet	*million dollars*
	Actual reported[c]							
1966	7	84	32	21	54	198	—	—
1967	6	81	40	21	59	207	—	—
1968	6	95	38	18	68	225	—	—
	Model projections							
1966	7	84	65	10	68	234	945	29.7
1976	7	84	63	6	65	225	889	29.1
1986	7	84	57	8	58	214	841	28.3
1996	7	84	46	3	44	184	730	27.2
2006	7	84	40	3	38	172	688	26.8

[a] The first three rows are reported acreage in 1966, 1967, and 1968. Data in all other rows are projections of the integrated linear programming—aquifer analog model.

[b] Barley, wheat, and miscellaneous other field crops are treated as a single activity, since net returns and resource requirements are practically identical at present. Barley is the more significant; in 1968, barley acreage was 47,800; wheat, 12,400; other crops, 6,350.

[c] Source: [2, 3].

Projected total cropped acres fall by 26.5 percent over the 40-year period. This is entirely because of rising water costs rather than from a physical shortage of water. Fewer acres of the low-valued crops will be grown. Acreage of high-valued crops, including cotton, vegetables, and citrus, will not be affected.

Annual water use will fall by 27.2 percent during this period. Use falls slightly faster than acreage because less water is used per acre as water costs rise and as farms become larger and more efficient water users. Use would fall even faster except that the high-valued, high-water-using crops become a larger percent of total cropped acres.

Net income over variable cost drops by only 9.8 percent during the same period. There are several reasons. Adjustments in total acreage are entirely of low-valued crops, which are even presently contributing little to net income. In 2006, a much larger proportion of the farms are large farms with lower costs of production. Finally, a larger proportion of total water use is from the small surface supply in the area. As hypothesized, the integrated model showed slower declines in the depth to water than the hydrologic model alone [1].

Conclusion

In this case study, assuming that exogenous forces such as the cotton program remain unchanged over time, the projected decline in net income over the coming 40 years was shown to occur gradually and to be relatively small in magnitude. Elsewhere, we have shown that augmentation of water supplies would be of questionable merit on economic efficiency grounds [5, 7]. It is also not clear that schemes other than "hands off" would prove superior if maximization of present worth of farmers of the area is the policy goal. In any case, the tools to test these hypotheses are now available for this and other groundwater basins.

"Solid Wastes"—A Resource?*

JOSEPH HAVLICEK, JR., GEORGE S. TOLLEY, AND YI WANG

WE are one of the most affluent, and *effluent*, people in the world. Recent investigations suggest that over a ton per person of various types of solid wastes is collected annually in the United States [4, p. 13] and over one percent of GNP is spent on collection and disposal [2, p. 3]. What are solid wastes? In addition to garbage and municipal refuse, solid wastes include wastes from commercial, industrial, agricultural, and demolition sources. The composition of solid wastes has been changing dramatically over time, and volume has been continuously increasing.

Pressing problems connected with this growing amount of material have been recognized in many cities and metropolitan areas, and efforts are being made to find solutions. However, solid waste problems are by no means confined to cities and large metropolitan areas. Failure to recognize solid waste problems in rural areas may be one reason why open dumps, open-dump burning, and littering occur and are making many rural areas lose their advantage over cities in environmental quality. As urban frontiers penetrate deeper into rural areas, solid waste problems in rural areas will become more critical. To add to the problems, sparsely populated rural areas are becoming prime candidates for location of disposal sites for wastes generated in large metropolitan areas. The need for attention to solid wastes is accentuated by the fact that governments in rural areas are not as well equipped in manpower, expertise, and other resources to deal with solid waste problems as are governmental units for cities and larger metropolitan areas.

There is an almost unexplainable void in economic analyses of solid waste disposal. The purpose of this paper is to probe economic issues in solid waste disposal and to suggest problems for analytical research.

Approaches to Solid Waste Disposal

A choice can be made in decision making for solid wastes of whether or not to benefit from the increasing awareness of values connected with environmental quality. Solid waste disposal entails transforming solid wastes into heat, gases, liquids, light, or other solid forms and putting these into

---

JOSEPH HAVLICEK, JR. *is professor of agricultural economics at Purdue University.* GEORGE S. TOLLEY *is professor of economics and* YI WANG *is research associate in economics at the University of Chicago.*

the environment, thus altering the environment. A social choice has to be made about the quality levels of air, water, and visual aesthetics. A direct choice can be made by enforcing standards regulating the disposal of solid wastes. Alternatively, the choice can be made by default, which usually leads to a deterioration of environmental quality. Once the environment is being degraded below a publicly acceptable level, it is difficult to bring about changes reversing the process. However, maintenance of environmental quality is not all or nothing. Questions are: At what level should environmental quality be maintained, and what costs are individuals and groups within society willing to bear to maintain those levels?

One of two general approaches to the disposal of solid wastes is the "destroy and get-rid-of" approach. This approach considers solid wastes to be a nuisance or at best "unwanted things" worth nothing. It leads to a choice of disposal methods that do not make use of characteristics of solid wastes that evolve from their transformation during disposal. The "destroy and get-rid-of" approach leads to choices of technical disposal strategies such as open dumps, open-dump burning, and incineration, which often result in a deterioration of environmental quality because of air or water pollution or adverse effects on visual aesthetics. A second approach is the "useful resource" approach, which emphasizes the use of solid wastes as inputs in creating things of value, ranging from salable products to an environment that is improved rather than degraded by the disposal activity.

Within these two approaches, attention must be given to strategies that refer to alternative technical methods of disposing of solid wastes. Solid waste strategies may be classified as either primary or auxiliary. Primary strategies are final stages of disposal and include sanitary landfills, incineration, composting, open dumps, etc.[1] Auxiliary strategies are intermediate processes which provide storage for or change the form or location of solid wastes. They are used in conjunction with and usually sequentially precede primary strategies.

Some primary strategies compatible with the "useful resource" approach are sanitary landfill, pyrolysis, composting, and reprocessing and recycling of metals and materials. A sanitary landfill is a nuisance-free disposal site in which the refuse is covered each day by a layer of earth that is compacted to provide a tight seal [5, p. vi]. Pyrolysis is a high pressure, high temperature, retort process, which produces water, gases, useful oils, and charcoal ash, from which useful by-products may be extracted. Composting entails decomposing solid wastes to usable soil conditioners. Reprocessing and recycling metals and materials ranges from separation and salvaging of one or few selected components to a decomposition of solid wastes to basic elements and recovery of usable elements.

---

[1] Some strategies classified as primary really are not final stages of disposal but are considered such by some in the solid waste industry. For example, incineration usually leaves 20–40 percent residue, which has to be disposed of; and in composting, there is compost and non-compostable items to be disposed of.

Some activities included in auxiliary strategies are: (1) various truck collection systems, (2) high density compression, (3) fragmentization, (4) grinding, (5) pulverization, (6) home refuse freezer, (7) transfer stations, (8) transfer trailers, (9) rail hauling, and (10) pneumatic collection systems. One or more auxiliary strategies may be combined with one or more primary strategies to form a meaningful set of strategies for some set of conditions in a given area.

Strategies need to be fitted into contexts. Contexts are other conditions, constraints, and related activities that are relevant to the functioning of the strategies. The strategies plus the contexts constitute a system [3, p. 50]. Decision problems concerning solid waste disposal faced by local governments involve choosing a solid waste disposal system for their particular conditions. This choice is frequently made without reliable and helpful economic information about alternatives.

Economic Issues and Research Needs

Economic research encompassing detailed and rigorous evaluations of benefits and costs of various strategies and systems would provide information that could immediately be helpful to local governments in making decisions about disposal systems. Although many procedures for evaluating benefits and costs of disposal strategies are straightforward, the sanitary landfill will serve as an illustration for identifying some of the more difficult conceptual and measurement issues.

People usually object strongly to having any type of a disposal site located near them, and the sanitary landfill is no exception. Many objections are not without basis. People living near a sanitary landfill may have external costs imposed upon them because of noise, dust, occasionally strewn paper, probably some odor at times, and congestion problems. These are at a minimum if the landfill is operated according to high standards. The value of property may decrease during the active life of the landfill; and if the property is sold while the landfill is in operation, the loss may be substantial. The location of a disposal site introduces risks that people in the area are asked to bear. An evaluation of the external costs and the types and amounts of compensation for these costs and bearing of imposed risks are important areas for economic investigation and are at the heart of welfare economics.

If geological and hydrological conditions are carefully considered and the landfill is operated with a view to sanitary and aesthetic aims, it is a recommendatory strategy from an environmental quality viewpoint. The intent of the sanitary landfill can be to transform land into an asset that will generate a higher rent than before. The solid waste is a factor of production in this transformation about which several economic questions should be asked. First, if the solid waste is a productive input in this process, it presumably has some economic value. What value? The tendency is to assign zero value to it. Second, completing landfills as rapidly as possible to generate the higher rent makes good economic sense. The present value of the shorter-lived landfill tends to be higher because the benefits are not deferred for as long a period of time. Because of difficulty and costs of opening sites, common practice is to strive for as large a site as possible, which usually takes from 10 to 20 years to complete. Length of active life of a landfill may be one of the factors that motivates people to object so strongly to disposal sites. Assessing alternative rates of filling sanitary landfills for various conditions merits research consideration.

In some cases, sanitary landfills are in effect reclamation projects creating usable land in areas where there is a shortage of land. With proper planning and landscaping, hills or "mountains" can be built from solid wastes which, when completed, provide ski slopes, toboggan slides, and other recreational facilities [6, p. 37]. One landfill in the Chicago area will provide a site for two golf courses, which ultimately will be converted to a cemetery. Some completed landfills produce outputs for which prices or rents are readily estimable, whereas other benefits are difficult to evaluate. Completed landfills are frequently used for playgrounds, parks, ball diamonds, and other similar recreational facilities and help to meet the demand for "user oriented" recreation [1, p. 38], one of the fastest growing demands. Furthermore, while providing recreational services, a completed landfill could concurrently be providing storage for materials to be recovered and reused at some future time. The linkages of solid wastes as a useful resource related to the supply and demand for recreational facilities particularly warrants research investigation.

The sanitary landfill has been discussed as an illustrative disposal strategy. Similar considerations apply to other strategies. Little is known about the short-run and long-run cost structures of combinations of primary and auxiliary strategies. Scale, as determined by size, and population density of the collection area influence costs of different systems. Evaluating strategies can involve complex estimation problems pertaining to purchase and/or leasing costs, opening and developmental costs, as well as the external costs mentioned earlier.

Beyond quantitative benefit and cost analyses, research is needed on the economics of laws, regulations, and private and public compensation, including proposed federal subsidies to encourage high standards of environmental quality. Analysis of how production, handling, and disposal are

EDUCATIONAL INSTITUTIONS IN TODAY'S WORLD

CHAIRMAN: MARSHALL R. GODWIN, TEXAS A&M UNIVERSITY

Mission of Higher Educational Institutions in Today's World

C. BRICE RATCHFORD

WE can say that the mission of institutions of higher education is being subjected to critical reexamination. That's about as much "news" as a couple of astronauts walking around on the moon. What may be really news is that the Cooperative Extension Service, often called archaic and cemented in tradition, has tackled the reexamination of its mission with vigor. Its report, *A People and A Spirit,* is the text I shall cite, paraphrase, and take off from [3]. It is a subject that has a special interest because most of us have lived and worked in the land-grant university tradition of combining abstract thought and research with applied service. From the way we see it, it is tempting to prescribe a large dose of the land-grant philosophy as the answer for higher education.

This line, however, only invites smug self-satisfaction—we dare not indulge. New educational forms, such as urban grant universities, are thought necessary by some. State colleges and junior colleges have issued the challenge that they—not state land-grant universities—are best qualified to reach and relate to close-by communities. So land-grant schools *must also* be included in our examination. Cooperative Extension's study was a giant step in this direction.

Today, higher education finds itself in a new position in terms of public interest and the role it should play in society. In past years, except in the uniquely different land-grant circles, higher education saw itself as charged with educating society's privileged class to serve as leaders in politics, business, cultural enrichment, and social matters. This remained the accepted role until the '30's and probably up to World War II. As such, it was of interest to few people.

An interesting aside—130 years ago when the University of Missouri's first campus was being located, the town of Columbia strongly preferred the state penitentiary and felt the loser by getting the state university.

Two major factors are responsible for the change in the place of higher education in society. The first relates to the real and prestige value of higher education. A college education has become a normal aspiration for

---

C. BRICE RATCHFORD *is vice-president for extension at the University of Missouri.*

a large segment of our affluent society. Several special federal programs, such as "Upward Bound" and "Work-Study," are attempting to make it a reality for the disadvantaged segment of society. The result? Soaring enrollments which, along with inflation, higher salaries, and higher academic standards, have so increased the total budget that the cost of higher education is of concern even to non-participants in higher education.

The second factor relates to the entire field of new dimensions that institutions of higher education have added to its duties, sometimes at its own initiative, but more often with urging from the outside. The role of the universities in developing the atomic bomb dramatically impressed the general public with what could be done to implement national missions. Most federal legislation of the last two decades, either explicitly or implicitly, has called upon the resources of higher education. Some legislation could not be executed without assistance from society's primary knowledge center—the university. The professions, business, industry, and labor have joined with the farmers in asking help and have received it.

No longer in question, except by a few traditional faculty members, is the *obligation* of the university to help society solve its problems.

The main reason for the almost universal acceptance of this obligatory position is a hard fact: The institutions of higher education are an unduplicable resource that society needs. The libraries, computers, laboratories, and, most particularly, the faculty have an absolutely unique capability to *assist* in solving some of the major problems of the world. The universities do not want to isolate these resources and society will not permit it.

A second reason relates to the nature of higher education. The higher education community strives to maintain a greater degree of objectivity than any other institution of society. It is more detached from the problems it studies and this not only contributes to objectivity but permits the role of critic, which in its way aids problem solving.

There is a myriad of relevant questions about every aspect of higher education but the clutch policy question of the day relates to the role of higher education in solving societal problems. However, no agreement has been reached on posing the issues, and this is part of our dilemma.

Two diametrically-opposed points of view were expressed in the 1966–67 annual report of the Carnegie Foundation for the Advancement of Teaching [4]. One extreme was stated as follows:

> . . . the university . . . should abjure any conception of itself as an activist shaper of the larger society. It should not "bite off propositions," develop "positions," or be a "protagonist" for causes. It should stick to the pursuits of the academic cloister with which it has traditionally been concerned and carry them out to the best of its ability. All else is illusory.

The opposite position was described this way:

> . . . among all institutions in the nation, the university has the greatest responsibility to be a shaper of the society. As such it has an obligation to identify social wrongs and take an aggressive lead in rectifying them. It must be engaged, activist, reformist . . .
>
> In this view, the university can best protect its position not by an attitude of aloofness from the great social issues of the day but by actively engaging in them. And this kind of activist role, far from detracting from the traditional functions of teaching and research, will actually strengthen them.

These generalities express the division in one way. There are others that relate to the problems to approach, how they are to be approached, and who decides what to tackle. In the quotations, the emphasis on the activist role focuses on the applied research and extension arms of the university; but, truly, it is an institution-wide concern. As an example, the resident instructional program is asked to help solve the problem of upgrading the disadvantaged. To do this, we accept a large number of students from a different culture and end up with a product competitive with the white upper-middle-class.

Administrators have been worrying about the role for several years, and the body of literature is growing larger. Some of the more prestigious contributors include John Gardner, Clark Kerr, Roger Heyns, Samuel Gould, Fred Harrington, T. R. McConnell, and Paul Miller. Recently, the key questions have been brought into the spotlight more by students and faculty.

One extreme point of view would have the university, in a corporate sense, serve as an instrument of direct social action. Few college administrators take this view, but this is exactly what many of the activist students and faculty want.

The reasons for such a view were summarized by Harris L. Wofford, Jr., president of State University College at Old Westbury, New York [5]:

1. The university must be concerned with and contribute to the common good. Any other position is untrue, which is inconsistent with the purpose of a university, and, furthermore, is selfish.
2. Colleges cannot but be agent of change; denying the role is an untruth or a camouflage.
3. Abdicating the role leaves a vacuum that will be filled by less well qualified and perhaps even dangerous people.
4. Direct involvement lends relevance to the entire university program.

The majority of administrators, faculty, students, and the public, while urging much involvement, feel that institutions of higher education should stop short of such an extreme position. One of the most articulate spokesmen for a more moderate view is Chancellor Roger Heyns. His argument is that such a course will strip the university of the very characteristics that make it useful in problem solving—its objectivity and detachment. It would also remove the arguments that higher education has successfully used to maintain academic freedom and the right of self-governance [2].

I strongly subscribe to a moderate point of view. It seems to me fundamentally wrong for the corporate university, or a faculty, to take and promote a stand on issues which do not directly impinge on the institution. This certainly does not imply that faculty members and students should not or cannot take positions and work as individuals to achieve certain goals. Let me add also that I feel the vast majority of institutions have not been sufficiently involved, that they have not come nearly close enough to the line that should not be crossed. So to an extent these arguments have been strictly academic; but they are not likely to remain so in the future.

There is considerable truth to Wofford's argument that a university cannot but be an agent of change. A basic purpose of higher education is to discover and disseminate new knowledge. New ideas, new technology, and new concepts are powerful motivators of major changes in society. It is one thing, however, for the corporate university to make it possible for new "truths" to be discovered and to make them known to decision makers and the public. But it is quite another thing to then actively campaign for action.

Let me give an example that indicates where I feel the line should be drawn, using a very controversial subject—slum housing. It would be entirely appropriate for a university to finance research on ways to improve slum housing. Perhaps one alternative is a rent strike and another an organized march on city hall. It would also be appropriate to make this information available to the slum dwellers. It would be totally inappropriate, however, for the university to proceed to organize the strike or march.

The criticism to be leveled at most institutions of higher education is that they have been insufficiently involved, particularly in the key social issues. Most universities have major programs for developing and disseminating new technology. There is good interaction between the university community and federal and state governments, the business community, farmers, and the professions. This interaction has helped the institutions and individuals solve problems and achieve their goals. Very little has been done, however, by higher education to come to grips with such problems as poverty, racial alienation, peace, slum housing in rural and urban areas, restructuring institutions, and many other pressing problems of society.

John Gardner, in what almost amounts to an indictment, has this to say:

> . . . Generally speaking, when one moves from the arena of scientific and technical problems to those problems involving change in human institu-

> tions, one cannot say that the Universities are a significant intellectual base for the main attack. In fact, a good many university people whose field should give them a legitimate interest in these matters barely understand what the relevant problems are. Many are debating policy alternatives left behind five years ago. Few are planning the kind of research that would sharpen policy alternatives [1].

I feel that Gardner has overstated the situation and that the universities can quickly become as capable in social engineering as they have been in physical engineering, if they choose to so do.

The need to identify and agree upon the Cooperative Extension Service's mission as an instrument of change within the higher educational community led to the establishment of a committee to study the institution. The committee's report relates a good case study of the problems involved in redirecting a well established, large-scale, decentralized institution. Many of the principles relate to the entire university.

The study was initiated because Cooperative Extension was in trouble. It was not under the immediate threat of being deliberately abolished or even sharply curtailed; but rather it was threatened with the prospect of a smaller number of clients and duplication from a number of new agencies in the USDA, other federal departments, and within the university. The once monolithic national structure was being undermined as an increasing number of land-grant universities changed their basic organizational arrangement of public service functions. This provided a division on goals within the organization. Farm organizations and the farm block in the Congress were becoming increasingly divided on the role of the institution. The most irritating criticism was that the institution had nothing to offer to solve the major problems of the day—even in rural areas. This was a common criticism outside the agricultural establishment.

The lack of vigorous redirection within the Cooperative Extension Service supplied the critics with ammunition. For years policy statements by the institution's leaders had said that much greater emphasis should be given to community problem solving, public affairs, improving the quality of the environment, and similar programs. No one ever got around to publicly criticizing the 4-H Club program, but it was clearly observed that the program was not reaching either the problem youth or the serious concerns of all youth. The home economics program in many states was tied to an association of clubs; and, as in the 4-H program, little effort was directed to the major problems of society and to individuals and families who had serious needs.

There had been much experimentation pointing out what could be done. In a few states, emphasis was placed on some of these new areas. When the national statistics were released, however, they showed little change.

and offered suggestions to both universities and the federal establishment for helping this potential become a reality.

The committee recognized that their proposals could not be implemented without some fundamental changes in organization and policies. Some of the more significant changes would include:

1. *Employing personnel from disciplines that can help achieve the program's objectives.* In most states almost every employee of the Cooperative Extension Service has his training in agriculture or home economics. The majority have majored in the technological area. In addition to these disciplines, other types of competencies must be made available.

The report also suggests an intensive program of retraining the present staff to handle part of the redirected program. Our Missouri experience clearly indicates, however, that only a small percent of the traditional staff can be retrained to handle radically different assignments; the redirection must come from new personnel.

The report recognizes, and again our Missouri experience confirms, that the broadened program cannot be achieved by simply making the new work an additional assignment for the traditional staff. In addition to a different type of training, specialized assignments are necessary.

2. *Having access to and contributions from every division of the university.* In the traditional pattern, almost all campus support came from agriculture and home economics. This was true even of the youth program. The necessity of total campus involvement is obvious; but the committee, and wisely so in my opinion, did not suggest how this goal could be achieved other than that it must be resolved at the presidential level.

While the committee was solidly behind this recommendation, it is one of the more controversial items in the report. Questions have come from every division of the university.

3. *Involving other institutions of higher education.* All Cooperative Extension Services funding has gone to the predominately white land-grant university in each state. This is in sharp contrast to today's pattern, which makes possible and encourages participation from all institutions of higher education in federally supported programs. The committee suggested that program responsibility continue to be centered in the same institutions. This is admittedly a prejudiced point of view, but active efforts should be made to work with *all* institutions of higher education. This could be accomplished through sub-contracts and joint appointments. Implementation, however, may well prove to be the most difficult task of all.

In most states with traditionally segregated institutions, the predominately white land-grant university has cooperated with the predominately Negro land-grant university. The specific relations varied, but control remained with one institution. The one issue that the committee was least satisfied with in its final recommendations was the role of the predominately Negro land-grant institutions in the program.

The difficulties arose, not from a lack of desire to help strengthen these institutions, but from the recognition that they need massive support which is far beyond the scope of Extension. Further, it would be unwise to build duplicate systems or even to duplicate some programs. The committee urged a greater involvement of the predominately Negro institutions on a *partnership* basis, along with increased funding to enable these universities to make a greater contribution. Hopefully, the contributions will be in program areas that will strengthen *both the institutions and the total extension program.*

4. *Having more positive relationships with total federal establishment.* The state extension services have had a fine cooperative relationship with the USDA. The results have been beneficial to all concerned. Contacts with other parts of the federal executive branch have been infrequent and on an informal basis. Parts of the suggested programs go beyond the mission of the USDA. Other federal departments have direct responsibility in some of these areas. No other federal department has established a nationwide education network, either on its own or in cooperation with the universities, although several are trying.[1] The committee suggested that formal agreements be developed with other agencies for continuing cooperative work. The logic behind the recommendation was that this was a more efficient method of achieving the desired programmatic objectives.

This brief overview makes it clear that significant movement in the directions indicated will radically change the extension service. It will become involved with some major problems of society in contrast to its former role as primarily a provider of technological services to a segment of the population.

Of greater significance is the possible impact on the higher education community. It is proposed that the organization serve as the outreach arm for this community. The concepts basic to Cooperative Extension operations that would not be changed are: (1) involving the target audience in program development; (2) casting the information within a problem-solving or goal-achieving frame of reference; and (3) encouraging the clientele to act upon the information received. Following these same principles in all of the suggested program areas will take the university closer to the action line that it had gone before. Moving further into the social, economic, and institutional areas suggested will place the university fully in the mainstream of the world.

It may happen that the report will not be implemented. In that case, it has been an interesting academic experience for those involved in its preparation. It is quite clear, however, that if the university had the goal of becoming effective in solving major problems it must devote its resources to the work and have some organizational plan for continuously relating university knowledge and resources to the larger community. Further, much of the work must be done off-campus. These requirements would make it necessary to have the equivalents of experiment stations and extension services in all fields. The committee felt that a single coordinated thrust would be more efficient and more effective in helping higher education carry out its proper role as an instrument of change.

---

[1] The USDA is trying to get one established through the STS Act; and HUD, through its Title VIII.

I will conclude with a question and a challenge to agricultural economists in higher education, government, and business. We are pleased that the report calls for more economics and therefore more economists, which will lead to a better market for our profession. I submit that this happy possibility will not be realized if we insist that our contributions be made within our professional ruts. I ask, is the profession improving its capacity to perform in the areas of concern that lie beyond the traditional farm management, marketing, and farm policy subject areas? Are we ready and able to subordinate our individual concerns and work together as a part of a physical and social science team on problems of environmental quality, economic injustice, regional planning, delivery of services to human, and other major problems of the day? I hope the answer to both of these questions is yes.

Social Science Needs in Agriculture and Natural Resources Curricula—The CEANAR Report*

CARROLL V. HESS

MY task here, in the brief time allotted, is to summarize the recommendations and the rationale underlying the CEANAR Committee's Report on the Social Science Education Needs for Undergraduates in Agriculture and Natural Resources Curricula. The Committee's specific charge was to recommend desirable education in the social sciences for undergraduates in agriculture and natural resources to fulfill:

(1) the liberal education dimension of their undergraduate education;

(2) supporting the professional education needs of undergraduates in non-social science majors, e.g., Agronomy, Animal Science, Food Science, Forestry; and

(3) supporting the professional education needs of undergraduates in the social science-oriented curriculum, e.g., Agricultural Economics, Agricultural Business Administration, Rural Sociology, Rural Community Planning and Development, Recreational Planning, and International Economic Development.

First, permit me to capsule for you the nature and magnitude of the social, economic, and political environment and issues that seemingly call for a greater understanding by faculty and students of the need for an increased role for the social sciences in today's modern university professional education.

American communities today are faced with massive social problems. The annual level of investment in the development of technology has reached the 23 billion dollar level in the United States. Seven billion of this is investment by the private sector, with the remaining 16 billion representing public investment in technology. These high investments generate enormous changes in capital input supplies and engender growth in goods and services of all kinds. As firms operate in this capitalistic society and respond readily to these huge injections of technology, increased specialization, economies to scale, and structural changes within the economy are accentuated.

Many communities are not prepared to meet these massive changes.

---

* This is an abstracted report of a committee to study recommended social science needs for undergraduates in agriculture and natural resources, appointed in 1968 by the Commission on Education in Agriculture and Natural Resources, National Research Council, National Academy of Sciences.

CARROLL V. HESS *is chairman of the CEANAR Social Science Needs Study Committee, a member of CEANAR, and dean of the College of Agriculture at Kansas State University.*

One measure of public concern is that in 1946, the Federal government spent 894 million dollars to help local governments augment their public programs. By 1966, this figure reached over 14 billion dollars, a 16-fold increase in a mere 20 years.

A myriad of community problems needs solutions—equitable taxes; educational expansion and relevancy; adequate local government; racial reconciliation; elimination of poverty; modernization of laws and public codes; improving the quality of the environment; the maintenance of public order under newer structural and social systems and conditions; sufficient health services; better transportation and communication; and finally the human desire fulfilled for beauty, dignity, and well being. Adequate progress toward solutions can arise only from citizens whose understanding is in perspective with the times. Science and education must be uniquely organized for the purposes of social innovation as they had to be for technological innovation.

Our land-grant universities were developed during a period in history that demanded expansion and application of the biological and physical sciences. The agricultural and forestry colleges, with their experiment stations and cooperative extension services, were among the great innovations in American social and economic history. This system of research and education was an important instrument in our developing nation through the invention and introduction of new technology. These technologies, which have freed us—or many of us—from hunger and want, have helped to create major social issues and conflicts. Thus, the committee felt it proper that we consciously examine the proper place in agricultural and natural resources curricula for the social disciplines to contribute to an understanding and resolution of the social issues arising as a kind of technological backlash from the massive injections of technology into agriculture. Technology has thus been a mixed blessing, by no means subjected as yet to effective social control. Furthermore, there have been few, if any, periods in which our social structures have been more critically challenged for their internal inconsistencies and inequities. Thus, the social sciences are directly charged with the study of society, which is today in turmoil. Social Sciences in this report refers to economics, sociology, anthropology, political science, geography, and psychology.

To excerpt from the committee report: "The social sciences focus on man's behavior and the ways in which he interacts with his fellowmen through social, economic, and political institutions to implement his aspirations and values. . . . Thus it is to the social sciences that we must turn if man is to assert his dominance over his technology and face constructively the manifold social issues of our time . . . without reasoned and objective approaches to these matters, we can rely only on expedience and luck to avoid chaos."

The committee recognized that agricultural and forestry colleges are properly concerned with professional education. At the same time, the student must live his professional and personal life in an explosive world with all its unresolved issues. While education in the social sciences cannot always yield instrumental social knowledge, it is vital to alert students to the man-created conditions that will persistently impinge upon the practice of their professions and their lives in the community.

Recent improvements in secondary school education have occurred notably in the areas of mathematics and biological and physical sciences. These developments have not been matched in the social sciences and humanities. Thus, colleges and universities have accordingly drawn the increased burden of sensitizing students in these disciplines to their changing social milieu and assisting them in interpreting it.

Although modern society has profited from the advances that have been made in the physical and biological sciences, it has found it increasingly difficult to adjust old institutions or to establish new ones to take full advantage of the new technology. The pressures created by our burgeoning populations have placed special emphasis on land-use conflicts and on the need for increased understanding of the complex socio-economic culture in which we live. Modern-day faculties and students alike are concerned about an educational process that produces persons filled to the graduation mortar board with "scientific" facts but fails to provide them with an understanding of the nature of man and of the institutions man creates in his attempt to optimize his individual and societal goals.

There is growing awareness that an agricultural and forestry "professional" is more than a "technologist". It is widely recognized that he must be an educated man who can adapt rapidly to changes in both technology and social goals and that in order to meet this challenge he needs a more liberal type of education than has traditionally characterized agricultural and forestry education programs. An example of one response to this need is the growth of two-year programs that produce technicians who can free the professional to concentrate on social problems of decision making, policy formulation, and public planning.

The variety of subject matter and career opportunities in agriculture and natural resources encourages some flexibility in developing social science training for agricultural students. The social science contributions to the production-technology or business options, for example, may be quite applied in nature, serving an "instrumentation" function. On the other hand, it may be more appropriate to use social science courses to create a philosophical background that should help students in agricultural science to appreciate both the biological science teachings and the applications of them in the service of humanity.

Likewise, in the natural resources area there are some special needs.

"People problems" involving political action, aesthetics, use preferences, and qualitative judgment have replaced the old problems of sustained yield, habitat manipulation, and methods of inventory. This transition is especially evident in outdoor recreation, a newly emerging field of resource management. As a result, educators in resource management are calling for greater social science contribution to their undergraduate programs.

In short, today's graduate of an agricultural or natural resources curriculum works largely with complex problems requiring a broad interdisciplinary background for their solution. He must be able to communicate with, and understand, something of the methods of engineers, planners, and social scientists who contribute to the analysis and solution of his problems. The undergraduate in agricultural or natural resources must have increased exposure to key subject areas in social science, if he is to help these teams of specialists to achieve their full potential usefulness.

Recommendations

The committee, in its report, defined the six social sciences involved and outlined specific ways in which each of these disciplines might contribute to the social science education of undergraduates in agriculture and natural resources. The time limitation will permit me only to outline their general recommendations as follows:

The committee emphasized flexibility—flexibility for the student to add new disciplines, including the social sciences, to accommodate the increasing maturity of today's students in professional colleges and their desire to achieve more specific goals. Social science courses taken early in the bachelor's program exposes him to a new fund of knowledge, shows him how social scientists perceive the world, and sensitizes him to a wider range of vocations and life styles. Flexibility also permits students to fashion a program more compatible with his specific professional needs and goals.

The committee specifically recommended that undergraduates in agriculture and natural resources devote 15 to 20 percent of the curriculum to the social sciences. We further recommended that the set of courses should include depth in at least two of the six social science disciplines and that the general education experience in the social sciences should be similar regardless of the professional specialization.

The recommended 15-20 percent allocation to the social sciences represents a significant increase in most instances. We felt justified in making this strong recommendation because greater progress has been made at the high school level in strengthening the student's foundation in the biological and physical sciences than in the social sciences. Little hope exists

Colleges, he had another vision: "The size, departmentalization and professionalization of the college with consequent bureaucratic behavior have destroyed much of the colleges' early flexibility and formal capacity for pragmatic problem solving, ..."

About the extension report under consideration, an editorial in one of the prominent national commodity magazines predicted: "We see being planted the seeds of disintegration of agricultural extension as an effective and dedicated service to farmers" [3].

3. *The agricultural establishment of the land-grant universities has continued to receive larger funding—surely one tangible evidence of citizenry support for research and extension.* The fact that long-run spending patterns of federal and especially of state and local governments for these purposes have trended upward is a matter of record. There have been exceptions, of course, in certain years and for certain states.

This hurried and very general historical perspective does not guarantee larger funding and broader services for the future for research and extension. But neither does it give the current crop of prophets of doom additional perception denied mortal man about a demise of the experiment station and the extension service.

My perspective does give credence to a hypothesis that the agricultural establishment in the land-grant universities likely will not only survive but grow as it provides increased needed services. In more pragmatic terms, these services probably will be around when those of us in this meeting retire.

Research and Extension Changing

The report, *A People and a Spirit,* a 95-page, two-year evaluation requested by the Extension directors, is appropriately timed for the tensions and ambiguities involving public service and is further tangible evidence that adequate sensitivity, perception, and adaptive capabilities do prevail in the land-grant universities [2].

As a matter of fact, extension and research have been shifting emphasis even with present funds. Considerably more emphasis is now placed upon policies affecting taxation, community services, schools, and related issues. Also included are special problems of people located in low income rural areas. "Test runs" are being made to improve opportunities for disadvantaged people in cities, e.g., through inclusion in 4-H activities and nutritional assistance programs.

Extension leaders today generally recognize that programs must be people oriented. They understand, as Paarlberg said in 1965, "Commodity programs treat some people as if they were fifty feet tall and others as if they were midgets. People oriented programs accept each at his own stature" [4, p. 20].

political party in power permit transfer of these new functions to less politically responsive institutions? For example, will the chairmen of the House and Senate agricultural committees react to a dilution of their perogatives and responsibilities?

The second determinant pertains to the power of *federal adminstrators.* Will the Secretaries of Health, Education and Welfare and of Labor support a policy of transferring city oriented functions to traditionally agricultural and rural oriented agencies? In recent years, they have been determined to originate policy for areas within their own commands.

The third set of the quad-aggregate determinants—the *economic institutions*—are effective participants in policy making, too. Owners of the larger commercial family farms, and even corporation farms, vertical integrators, and directors and managers of cooperatives illustrate the agri-economic institutions I have in mind. These superb strategists want to know whether the expanded research and extension program will assist them substantially in reaching the ends they seek. They want answers to such specific questions as: Will these institutions help us in gaining more market power? As large farmers and agricorporations, why should we pay extension for educational assistance?

The fourth and final determinant is *interest participation.* How far will the farm groups support the land-grant university proposals? Which group will fight, and to what extent, against increased funding? And what about the attitude of the whole gamut of national business associations, labor unions, and the increasing numbers of groups proclaiming to protect the consumer?

The power structure of three of the four policy determinants—the political institutions, the economic institutions, and the pressure groups—was not formally involved in the "People and a Spirit" study. This may prove to have been a mistake. Inefficiencies, resulting from lack of proper understanding of policy determinants, could result in the fading away of the excellent targets enunciated in the report and the assignments going to less deserving, but more politically astute, agencies.

Guidelines for Corrective Measures

In addition to reading and weighing properly the external determinants affecting them, the experiment stations and the extension services must see that proper guidelines are established and necessary corrective measures are taken in their own organizational structure to insure appropriate and effective programing, leadership, and subject-matter areas. I believe they will.

Here are a few guidelines:

1. Additional skills and insights are necessary to generate more effective group decision making on matters of social and economic develop-

ment. Group decision making is far more complicated than individual decision making.

2. Extension and research functions must be thoroughly understood and amply supported throughout all sectors of the university and by the president and the board of directors. The total knowledge base of the university must be accessible and usable with very short notice. There is no place for institutional rigidity in today's ball game.

3. Extension and research must gain access and rapport with the other federal agencies with which there will be cooperation equal to that enjoyed with USDA. This will not be an easy task, for even the rapport with USDA is not what it once was.

4. The land-grant universities must effectively demonstrate and communicate to the executive and legislative branches of government and to the farm and non-farm publics served that it is far less costly for the extension services and the experiment stations to provide needed assistance than to establish new parallel urban agencies.

5. Sometimes, professional staffs experience difficulties, after working with "commercial people," in adjusting to work with low-income groups and low-income alienated groups. These difficulties can be overcome through study and practice. A sociologist shocked the negro agents in one state in a meeting by pointing out they did not really understand the low income negro problem because they were actually middle income citizens.

6. Training the field personnel of agribusinesses, as the report calls for, will require delicate and persuasive maneuvering, and by extremely competent personnel. Some of these agribusinesses are in the training business now. Farmland Industries has recently developed a program to help local cooperatives find new employees. They plan to train some 300 rural persons under a contract between the Cooperative League of the USA and the U. S. Department of Labor. Farmland is the subcontractor. Consultation on educational phases will not be with the land-grant university or USDA personnel but with the U. S. Department of Health, Education and Welfare.

7. As agricultural economists, we need to return to devote a greater part of our time to areas formerly described as *institutional economics* and *political economy*. Hardin's concept of *programmatic research* also should receive more attention [6, p. 359]. This is making an analysis of the agricultural and nonagricultural governments in the United States. Hardin believes this type of research and extension work is needed urgently to provide a safeguard for a vigorous federalism, rather than the creation of irresponsive central agencies which may overreach themselves [6]. Such studies and educational work would provide also a clearer insight of the opportunities for additional funding for research and extension.

Summary and Conclusions

My overall conclusion is optimistic: The state experiment stations and the state extension services will continue to make policy and program adjustments, but not of the magnitude nor substantive content deemed desirable by the agricultural economists—nor the animal scientists for that matter. But the administrators will do so in terms of the power structure in the four determinants of policy making in the United States. Consequently, political support for continued increases in funding and services in the decade ahead will be forthcoming.

To be specific, if I were a young man, I would not feel insecure about doing my graduate work in agricultural economics and accepting a position in either research or extension, or both, in a land-grant university. First, I believe we have a right to be as proud of the achievements of our profession as are members of other subdisciplines of economics, whether monetary or labor economists or economic theorists. Secondly, I believe our land-grant universities are competing well with other great universities and cooperating agencies.

In short, the land-grant universities and the agricultural economists have the demonstrated competence to compete successfully in the future —if we want to—and if we are determined to do so.

AGRICULTURE IN THE ECONOMY OF THE FUTURE

CHAIRMAN: GEORGE E. BRANDOW, PENNSYLVANIA STATE UNIVERSITY

On Institutional Obsolescence and Innovation

LEO POLOPOLUS

> "The social system you save may be your own."
> —Kenneth E. Boulding

COMPETENT, extensive, readable, provocative, and relevant describe James Duncan Shaffer's public policy essay published in the May issue of the Journal for purposes of professional dialogue and debate [16]. The paper is remarkable because it demonstrates the enormously widened aperture of the contemporary agricultural economist in matters of policy. One need only to review the previous works of Benedict [1], Halcrow [7], Shepherd [17], Paarlberg [12], and even Hathaway [9], for example, to confirm this notion.

As a cursory overview, Professor Shaffer's paper deals with six broad aspects of public policy affecting or affected by our institutions: the social system and the effects of technology upon the system, external effects, protective and bureaucratic institutions, industrial organization and competition, community and economic development, and finally, the role of the professional agricultural economist in public policy research.

Shaffer concludes that both public and private institutions are becoming obsolete in terms of protecting society's general welfare. The rate of institutional obsolescence is positively influenced by the rate of technological change. Protective institutions are created by vested interests to protect monetary gains of the scientific-industrial process and to vitiate negative effects. The external effects, mostly external diseconomies, are pervasive symptoms of the social order. What are needed are innovative institutions to redress the organization of markets and communities to lessen the problems of the disadvantaged and to provide a more equitable distribution of the wealth created by the economic system. A plea is extended to the agricultural economist to contribute to the reformulation of viable institutions, particularly in rural areas. Specific comments and interpretations of Shaffer's paper are presented below.

The Social System and the Effects of Technology

Shaffer, as did Galbraith in *The New Industrial State* [6, p. 20], correctly posited the mutual interdependence of technology and social or-

---

LEO POLOPOLUS *is professor of agricultural economics and assistant dean of the Graduate School at the University of Florida.*

ganization. Technology cannot properly replace social engineering [20, p. 52], but it can serve to perturb the social nostalgia that continually persists and resists change. Galbraith [5, p. 138] and Eric Hoffer [10, p. 3] both argue that certain conditions must be present before change is introduced and effective action taken. Shaffer does not specifically mention the "shock effect" of the scientific industrialization process, but apparently implies that the shocks of change are absorbed by those persons and institutions least able to mitigate their effects. Also, the extreme and pessimistic view of French sociologist Jacques Ellul, that technology is so extensive that it controls and dehumanizes society [4, p. 54], is obviously rejected by Shaffer's optimistic hope of finding corrective and innovative institutions.

What becomes clear from a reading of Shaffer and other works on technology and social change is the lack of a uniform theory or at least a set of rules that states the relationships between certain types of technological conduct and the performance effects within the system. What is needed, for example, is a set of institutional innovations based upon scientific knowledge, less random and uncertain in their consequences and more fully in accord with man's desires [11, p. 542].

The view by Shaffer that the social system is dynamic is undeniable. However, his belief that dynamic systems cannot be described by models seems to throw excessive cold water on empirical attempts to develop such models. The conceptual framework of a systems model developed by Langham, for example, is specifically oriented toward societal and institutional change that is continuous, renewable, and responsive. Langham's approach involves incremental improvements to systems performance and it purposefully includes conflicting interest groups [12].

External Effects

Shaffer leaves no doubt that the present institutional arrangements are inadequate to deal with the problem posed by externalities. His hypothetical sketches of the DDT and river pollution cases are strong indications of his keen insight. While some external effects may be beneficial or economical to the system, such as pretty girls and well-landscaped lawns, Shaffer emphasizes the external diseconomies case. This is correct and relevant since external diseconomies, not external economies, cause public policy problems.

There are three alternative courses of action available to deal with serious external effects—contracts, internalization, and regulation. Contracting may occur when the party imposing the external diseconomies is willing to negotiate with the suffering party to their mutual advantage. Internalization would require that all of the effects be absorbed by a firm or a group of firms. Both private contracts and internalization, however, are not suitable to lessening most of the externalities adversely affecting the social system. And while regulation generally limits the external effects, the imposition of a tax to thwart bad external effects may be unwise without thorough examination of the situation [18, p. 309]. Shaffer does not clearly point a finger on an approach to ameliorate the harmful effects of externalities.

Protective and Bureaucratic Institutions

Shaffer argues that protective institutions are established to modify the marginal adjustments of the market and prevent Schumpeterian creative destruction. One could extend the discussion of this point and suggest that a code of institutional ethics should be required to circumscribe the actions of these institutions within the general public interest [15, pp. 193–203]. It is too easy for large corporations and other bureaucratized institutions to say, "What is possible legally, politically, and economically is therefore ethical." Our need is to search for new forms of organizations that might broaden the ethical purposes and socially beneficial influences of corporations, federations, cooperatives, nonprofit organizations, professional societies, trade and industrial associations, governments, and churches.

Industrial Organization and Competition

Despite the fact that considerable aggregate wealth is concentrated into the hands of the largest 100 corporations, industrial organization economists generally argue that the evaluation of competition is relevant only in narrowly defined product or service markets [1, p. 92]. Shaffer does not articulate his position very well on this matter. He should have tied his discussion of corporate bigness more closely to the emerging and potentially harmful effects of the conglomerate firm. Conglomerate mergers accounted for 84 percent of the number and 89 percent of the assets of all recorded large acquisitions in 1968 [19, p. 3]. While conglomerates are a special kind of protective institution, economists have not sufficiently analyzed their impact upon individual industrial markets nor their overall effect upon society's welfare.

In the food industry the large corporation has been able to proliferate new products with bewildering rapidity and ingenuity. Shaffer is well aware of these developments and is appropriately concerned about the ultimate consequences. He raises a fair question: Will the "inferior" analog or substitute win in competition with the "superior" traditional food? This problem cannot be as readily answered, as implied by Shaffer. The related public policies that deal with the problems posed by synthetics and agricultural substitutes involve the traditional agricultural policy, policies dealing with the health and welfare of consumers, antitrust policy, and policies affecting public research and development expenditures. It has been argued elsewhere that changes are needed in public policies affecting both the agricultural and nonagricultural dimensions of the problem [14].

Community and Economic Development

The strongest section of Shaffer's paper deals with his accurate perception of poverty in an affluent society. Technological displacement, the failure of farm policy to lessen the incidence of poverty, alienation between governmental agencies and the people presumably being assisted, the negative effects of the property tax for home improvement, the obsolescence of local governmental institutions, the maldistribution of income, and the denial of "new property" to the disadvantaged are some of Shaffer's main points.

Shaffer's proposal to create a federal mutual fund to give the poor a slice of some "new property" seems reasonable in principle, but the specifics do not appear workable. While innovations are increasing at a rapid rate, there is little evidence that the public research sector has provided a substantial volume of commercially feasible products and techniques in relation to the private sector. Much of the public sector's research is basic in origin. There is also no assurance that the innovative contributions of the public sector will provide a continuous or adequate flow of revenue to the mutual fund. It is doubtful that a fund so conceived could alleviate much of the prevailing poverty or redistribute incomes in any meaningful way.

The Role of the Agricultural Economist

Many agricultural economists are able and willing to accept Shaffer's challenge to become more involved with the broad and complex aspects of social change. Unfortunately, they must do so usually within an internal work environment that seeks to avoid controversy and an external atmosphere that questions the role of the agricultural economist. The internal research environment is hampered by administrative and political resistance [8, p. 227]. Externally, economists, like Boulding, argue that there is a misallocation of intellectual resources within the United States, and that, like medicine and law, agricultural economics drains a disproportionate share [3, p. 111]. Aside from the inconsequential lobbying activity of our protective institutions, e.g., professional associations, agricultural economists must demonstrate their responsiveness by individual deed and action. So far our contribution has been negligible. Hopefully, Shaffer's article will start some wheels rolling.

I See It Differently*

RADOJE NIKOLITCH

DEEP in the root of Professor Shaffer's article is a philosophical credo that shapes all its aspects—beginning with the motto, expressed concerns, interpretation of developments, and trust in innovations. The concept of changes is so overwhelming that it gives the impression of being a crusader's banner rather than a yardstick for measuring economic, social, and political events.

I have read and reread the article with great interest. It is an excellent and inspiring article—but, somehow, I am uneasy about its lack of critical balance, and I cannot acquiesce in its reasoning. No, I do not believe that "we must rethink all our old ideas and beliefs before they capture and destroy us." May I suggest that such a motto is not without emotional appeal and political orientations.

Let us modify the concept and say: We must adapt ourselves to new circumstances. Have we not done this since the beginning of the world? In such a gradual process of action and reaction, neither our old ideas and beliefs will capture and destroy us, nor would we be tempted to destroy them. This way we can meet new challenges and still keep the treasured institutions of our western civilization, which have passed the hard tests of centuries of historical reality.

The aim of this brief paper is not to suggest solutions for all of the issues raised. For this I lack the confidence and optimism so abundant in Professor Shaffer's article. The limited length of this paper also necessarily restrains its scope. However, I shall raise my doubts, first, about some of the interpretations of the process of institutional obsolescence, and second, about the "necessary activity" of institutional innovation. This I intend to do, not by elaborate discussion of concrete developments, but by a general glance at the basic problems. Or, to express myself more directly, by cautioning against overestimating the power of change and having too much optimism in innovations.

Obsolescence and Innovation

Whatever is new has a long history. Novelty is only a long process of adaptation. This is the natural law of survival, from which human society is not exempt. Of course, things are changing and our survival and suc-

RADOJE NIKOLITCH *is an agricultural economist with the Economic Research Service, USDA.*

cessful life depends primarily on our capacity for adaptation. What happens today started a long time ago, and because it happened, nobody is the same as before. But adaptations and changes cannot be separated without grave dangers. There is also a fallacy in believing that changing by itself means bettering. "History suggests some doubts about this."

The frightening rate of population increase could not be sustained without a mammoth technological advance, which in turn is prompted by the survival efforts of the growing billions of people. The anthropologists suggest that the structure of our hands shaped the development of human beings, but there is no doubt that what we put in those hands shapes human civilization.

It seems that we all agree on the inevitability of change. Our differences lie in where we put our emphasis. This seems to boil down to the question about *how* changes should be made and *who* should make them. In this respect I cannot but admire the English common law. There, wisely, new aspects of human activities, behavior, and interrelations are left to the reality of life itself; and, when commonly accepted as a practical or ethical rule, they are recognized by the courts and become law. It is wonderful how Great Britian liquidated one of the biggest world empires, without, practically speaking, changing any of her basic institutions.

It seems to me that our human society was always better off when changes came through the grind of life itself than through the wisdom of planned innovations. Democracy, which is in essence a compromise and balance of conflicting human interests, is the best fitted institution for the somewhat slower process for changes through adaptations. Certainly, our profession can contribute greatly to make that adaptation easier and more efficient—mostly by presenting to the society the alternatives that result from our scientific endeavors. For those among us who have also the privilege of being professors—by giving the best possible education to the oncoming generation. Indeed, education is the best hope for human progress. Whatever else we do, we cannot succed in making a better society without bettering men themselves.

It is evident that, through different concepts about change, the problems before us reflect themselves differently. It is like looking through variously colored glasses. Let us mention briefly how some of the problems raised by Shaffer can reflect themselves.

Some Different Outlooks

The main concern expressed in his article is about "a growing discrepancy between the quality of life enjoyed and that which is potentially attainable" [1, p. 245]. Through my glasses, I see "life enjoyed" getting better for an increasingly larger number of people—at least in free and democratic societies. "Life potentially attainable" is a nebulous concept;

hence, the measurement of the gap between them is more an emotional process than anything else.

Through the same glasses, I see primitive men in their wilderness at least as interdependent on each other (food, defense) as in presently scientifically industrialized societies. Also, the assumption that men are now less dependent on nature than before [1, p. 246] can hardly be substantiated—let us not forget our grave concern about the possibility of a forthcoming catastrophic hunger crisis.

I see adjustment of our institutions to new circumstances as an imperative. Not less necessary are due processes of legislative and administrative activities, in order to organize and manage our society the best way we know how. However, I am skeptical that much good could come of an "organized intellectual effort directed at institutional innovations" [1, p. 246]. First, I do not know whether "intellectual effort," once organized toward a specific social goal, could retain its intellectual independence and scientific aloofness. Such an organization could result in creating a new bureaucracy (as if we did not have enough of it throughout human history)—and that might not be the worst of it. Second, although I look at science as one of our best hopes, I cannot commend the direct participation of scientists in the management of our society. Good advice to researchers in any scientific field probably would be: *Find the truth, and the truth will find its way to usefulness.*

Technological displacement [1, p. 257], income distribution, and the "new property" [1, p. 260], under whatever aspects treated, are old social problems. Technological displacement is followed always by painful readjustment for some groups, but it is indispensable for progress. Are we not justifiably proud that our technological advance in farming released so much labor force for other social tasks? Neither our institutions, nor technology, nor "property tax" could be responsible for the fact that some segments of some communities remain alienated—outside of total social integration. The causes of this alienation are many-sided, some of them are tragically serious. If an able-bodied human being stays for a long time unproductive, and as a consequence unprotected, the tragedy of his situation lies in his unproductiveness.

This tragedy cannot be eliminated through help, whether called welfare, grants, or "new rights" [1, p. 262]. Besides natural and social disasters, individuals or groups of individuals throughout history have been unproductive mainly either because equal opportunities were denied to them or because they were unfit to take advantage of opportunities that were available. In either case, the ultimate remedy was and is still today in education. Our colleges and universities can make an important contribution in this respect, much more than by "nurturing the social critic and support extensive dialogue on issues of public policy" [1, p. 264]. Education is overwhelmingly important for solving our social problems. However, we should not forget that *discipline* is the first step towards education; and *self-discipline,* toward a successful and happy individual as well as social life.

Through my glasses, the creation of "the U. S. Inheritance Mutual Fund," which "would own, in the name of the citizens . . . rights of all scientific discoveries, inventions, and commercially exploitable ideas which derive from the work of scientists and technicians supported by Government funds" [1, p. 262] looks as unpracticable as theoretically twisted.

Tremendous readjustment in farming, and the impact of the readjustment to its organization, is a good example of the limited power of changes. Despite the profound changes that are in the offing, farms continue to be mostly relatively small, family-operated, and family-owned business—95 percent of all census reported farms and 64 percent of total farm marketings. Self-employment continues to be the dominant labor force in farming—75 percent of total farm employment. Farm managent continues to be widespread, and farmers continue their firm control over farm production resources, including land itself—mostly through ownership.

Finally, let us look through my glasses at Professor Shaffer's last statement that ". . . a meaningful life for all the members of our society is limited only by our will and creativity in structuring our institutions" [1, p. 266]. A meaningful life for all is a human dream of long standing, a goal to which I wholeheartedly subscribe. But to believe that we can achieve this goal by "structuring our institutions" is a dangerous illusion.

At the beginning of my comments to Shaffer's article, I suggested that the article is not without emotional appeal and political orientations. Looking at my comments, I see that they too are not entirely exempt of emotional appeal and, maybe, of political flavor. My only excuse is that I necessarily had to pass through a door that Professor Shaffer widely opened.

Institutional Engineering—Venture into Applied Behavioral Science

DAVID H. SPAETH

I APPROACH the task of responding to Dr. Shaffer's article with some hesitancy. It is a bit frightening to work in a remote corner of the full range of activity in agricultural economics and then to find that many of the once remote issues and concerns have become central.

I make no apologies for the personal nature of this paper. It is in the nature of a travelogue—a report of adventures in the world of applied science from the frontier of the urbanization of rural America and the jungle of state governments in transition. There have been two vehicles for this exploration: first, extended participation in the design of programs for Appalachia and other developing areas of Kentucky, sponsored by three successive governors of the state; second, participation in the activity arising from a Ford Foundation grant to former Governor Edward T. Breathitt of Kentucky to continue and extend the work of the Commission on Rural Poverty.

To continue the metaphor, it is my intent to point out some principal features of the area of applied institutional engineering, the problems likly to confront the venturer, and to comment on appropriate equipment. More specifically, I wish to deal with the hierarchical nature of goals in the world of goal-oriented systems used in development programming; with the confrontation between invention and trend, budgets and imagination, planning and programming; and with the nature of the practice of applied behavioral science.

Hierarchies of Goals

This particular discussion is direct toward the following statement from the Shaffer article [1, p. 246]:

> Effective public policy requires management of the evolving system, and effective management requires an understanding of the dynamics of the system. But even more, it depends upon organizing our institutions to direct the system to achieve desired goals rather than accept whatever pattern organization evolves.

It has been my experience over the past several years that the accurate identification of goals has been the most critical and most demanding element of deliberate institutional innovation and engineering. The meetings and interview sessions that lead to the phrasing, rephrasing and refine-

---

DAVID H. SPAETH *is a consultant in developmental systems design and staff consultant to Spindletop Research, Inc., Lexington, Kentucky.*

ment of statements of organizational charter or mission often take on many of the characteristics of psychoanalytic sessions.

To illustrate, one principal activity in which I have been able to participate is the construction of management information systems for units of state government charged with management of the state's water resources. The need that usually initiates the move to set up such a management information system is the desire to improve the response capability of the state agency to the demands for data analysis by decision makers. The adoption of the need as a goal usually leads to a move to establish a computerized data bank. Such a move never addresses the questions as to the adequacy of the existing data, what new data is worth gathering, and what useful new analyses could be performed with the expanded data-processing capability. In each case, in order to establish a useful, workable, and reasonably efficient system, it has been necessary to exhaustively ferret out the mission of the state agency within the framework of the larger governments. When the unit in question is a planning and research arm of one division of one of a dozen agencies dealing with water resources, the identification of goals can become a sensitive and even explosive activity.

The hierarchical nature of goals has been implicit in the foregoing example. It became explicit when we at Spindletop attempted to give some structure to the many recommendations of the Commission on Rural Poverty. It became very obvious that some of these recommendations entail changes in broad national domestic policy; others require changes in the structure of implementing agencies; still others, changes in the missions of these agencies. We are presently engaged in "prioritizing" these recommendations to form a workable set of goals, with some sense of sequence and logical interrelationship. We feel this is necessary to the formation of a national program to deal with the problems of rural poverty and to bring the very large cost into perspective.

May I comment in passing that my work with the recommendations of the Commission on Rural Poverty has led me to the conclusion that the very broad statements near the top of the goal structure for dealing with rural poverty will have to include some explicit statement of position or policy with regard to rural settlement patterns and domestic income distribution. Both of these issues are recognized in the Shaffer article [1, pp. 260–261].

Planning and Programming

The terms planning and programming can almost be labels applied to battle lines. In the regional development business, the battle shapes up between those who would evaluate and predict the viability of a community or area and those who design programs to materially alter the basic factors and assumptions underlying the evaluation and prediction. Within state government, the lines are drawn between those desiring to forge programs to solve problems within the state and those who worry about allocation of state revenues. In federal-state relationships the tension develops as state-level program developers engage in "grantsmanship" and the federal employee seeks to defend his judgments by constructing "objective" allocation formulae. These tensions strike hard at the economist who gets caught up in program design. Starting with the classic definition of economics as a science dealing with the allocation of scarce resources, it is disconcerting to work with the notion that if the time constraint is relaxed the resources are not so scarce. Add to this the non-additivity of individual projects that are mutually supporting, and many of the more familiar tools of economic analysis become inappropriate. My own statement has been that in area development programming it is not necessary to say "no" to anyone, just "tomorrow." The problem of Smithsville's school vs. Jonesville's hospital is solved by saying that both will be built in some sequence that makes sense in terms of the more comprehensive program in which the projects are embedded. Viewed in this fashion, the aforementioned antagonisms find their resolution by defining the comprehensive program of activity. The program process is then paced by politically determined funding, in turn influenced by program content. The plan and accompanying budget are then that part of the comprehensive program and funding falling within a given time span. In this way the allocation problem is solved by the programming process. Ideas are funded, rather than the reverse situation where ideas are attached to a priori allocation based on some distributional equity.

The Practice of Applied Behavioral Science

The above comments point to some of the characteristics of working in the area of applied research. First, it is problem oriented, hence, customer-oriented. The problem is not that of the scientist—who must consciously avoid personal projection. Listening is an admirable skill. Second, it is usually the application of known principles to pursuit of stated objectives. Seldom does one investigate the basic nature of the mechanism or dynamics with which one is dealing. Third, since the problem is presented from the so-called real world and the answers by and large known, the basic skill involved is articulation of the appropriate questions. Fourth, since the problems and question refuse to conform to disciplinary lines, one must develop a multi-disciplinary capacity to perform. This does not mean that to be successful the worker must be all things unto all people. It does mean a knowledge of the lexicon of disciplines beyond his own specialty. The economist must be able to converse with the lawyer, tht sociologist, the psychologist, in a meaningul way and with a minimum of semantic hangups. This not only takes time; it takes patience, because

FIRST AWARD PAPER IN THE UNDERGRADUATE STUDENT ESSAY CONTEST

Consumer Preference for "Imitation" Milk Beverages

ALBERT W. GUSTAFSON

> "Things are seldom what they seem,
> Skim milk masquerades as cream."
> —Gilbert & Sullivan, *H.M.S. Pinafore*

"IMITATION" milk is not new. Production records of 1916 show 6,400 metric tons of "imitation" milk processed in that year alone [13, p. 38]. However, during the past few years sales of non-dairy and partially non-dairy products have increased rapidly.

There are two broad categories of imitation milk: (1) a beverage containing non-fat milk solids with the milk fat replaced by vegetable fat (henceforth referred to as filled milk); and (2) a beverage containing no milk products (henceforth referred to as synthetic milk) [9, p. 17].

Either of the above types of milk would have adverse effects on the dairy industry should it capture a substantial part of the fluid milk market. Available data indicates that filled milk products enjoy a constant and rapid increase in sales. In the federal market order areas of the United States, filled milk sales increased from 2.4 million pounds in November of 1967 [16, p. 23] to 4.9 million pounds in April of 1969 [17, p. 24]. No comparable data is available for synthetic milk.[1]

The major problem faced by the dairy industry is the price advantage enjoyed by the "imitation" products. A recent USDA publication compared the price per one-half gallon for raw materials used in whole milk, filled milk, and synthetic milk. As shown in Table 1, the cost difference per one-half gallon between whole milk and filled milk (using Class I fluid skim milk base), was 6.5 cents per one-half gallon. The difference in cost between whole milk and synthetic was 14.2 cents, while the difference between filled milk and synthetic milk was 7.7 cents.

The best case history of filled milk sales is found in the Central Arizona marketing area. "Go," marketed by Sarival Guernsey Farms [14, p. 36], has grown from 1.3 percent of regulated pool plant (Class I) sales in October, 1966, to 11.5 percent of sales as of August, 1968 [9, p. 21].

---

[1] Volume data are not available. However, in April, 1969, there were four federal order markets in which the synthetic product was being sold [17, p. 24, Table 13].

ALBERT W. GUSTAFSON *is a senior in agricultural economics at Southern Illinois University.*

Table 1. Comparison of estimated ingredient costs for whole, filled, and synthetic milk

Ingredient	Whole milk[b]	Filled milk: Nonfat dry milk[a]	Filled milk: Class I fluid skim milk[b]	Synthetic milk[c]
	cents			
Fluid skim milk (Class I)	15.2	—	15.2	—
Nonfat dry milk	—	9.4	—	—
Vegetable oil	—	2.7	2.7	2.7
Milk fat	12.0	—	—	—
Protein	—	—	—	5.7
Emulsifiers and stabilizers	—	2.8	2.8	2.8
Buffers, sweeteners, and body agents	—	—	—	1.8
Total	27.2	14.9[d]	20.7	13.0[d]

[a] Based on nonfat dry milk at 24.5 cents per pound, refined vegetable oil at 21 cents per pound and base mix (emulsifiers and stabilizers) at about $3 per pound.

[b] Based on the April 1968 price of $6.33 per cwt. dealers paid for 3.5 percent milk and a Class I butterfat differential of 8.0 cents.

[c] Based on soy protein costs of 37 cents per pound for protein source.

[d] Even though water composes slightly over 87 percent of the product, the cost per one-half gallon is less than .01 cent.

Source: [9, Tables 3 and 4].

In 1966 only about .02 percent of the total monthly Class I sales were filled milk in California. By August, 1968, this figure rose to 1.3 percent of total Class I sales [9, p. 21].

Without a doubt, Hawaii possesses the award for phenomenal imitation sales growth. In August, 1967, imitation sales were 0.1 percent of Class I sales; by December of the same year, imitation sales in the same market (Honolulu) had grown to 20.4 percent. This growth has tended to level off at about 20 percent of Class I sales. April, 1968, saw imitations holding 19.7 percent of the market [9, p. 21]. This unparalleled growth rate was brought about through intensive promotional activities, combined with a price differential of approximately 20 cents per one-half gallon [9, p. 21].

The Midwest has also had filled milks, but whole milk has been able to hold a large percentage of its markets because of competitive component prices.

Objective of Study

The major objective of this study is to estimate the potential impact of filled and imitation products on the dairy industry.

The ideal test would consist of acceptance of the product by the consumer under actual market conditions. However, under actual market conditions it would be impossible to hold constant all the factors that might affect purchases of the three products. The extent of advertising, retail pricing policy, and the whole assortment of marketing tools would be possible influences. Taken collectively they would have an effect on consumer purchases as well as on the product itself.

To keep the study manageable, the objective was narrowed to determining the consumers' preferences of whole milk, filled milk, or imitation milk. The use of the word preference can be justified from the standpoint that "preference accounts for 35–60 percent of the variation in consumption, . . . and . . . (it is) unlikely that any other single variable would be found effective in predicting acceptability. It has since been determined that 75 percent of the variation in acceptance of army food can be predicted from preference data . . ." [3, p. 583]. Therefore, if relative consumer preferences of the products can be determined, a large proportion of consumer acceptance will be explained. If this is true, merchandising actions may be taken to expand the sales of the product.

Procedure Used

A taste test was conducted at three grocery stores in Carbonadale, Illinois. The stores were chosen so as to obtain a cross-section of the population. One store was located on the east edge of the city, one in the center, and one on the west edge of the city.

The taste test consisted of asking the consumer to taste one ounce of each type of milk (whole, filled, and synthetic) and to register his preferences and other pertinent information on a questionnaire.

To determine relative consumer preferences for whole milk, filled milk, and synthetic milk, the Hedonic Rating Scale was utilized. The Chicago Food Acceptance Research Laboratory developed the 7-point Hedonic Scale, using the terms like and dislike. They did so with the intention of its being used with a single food stimulus by judges having no experience in food testing. The scale was first reported by Peryam and Giradot in 1952 and was later expanded into the 9-point scale [10, p. 1310].

The Hedonic scale has two essential features: (1) it assumes a continuum of preference; and (2) it causes the respondent to categorize his answer in terms of like or dislike [11, p. 11]. In relation to the first feature, the scale is more useful for determining preferences than for determining differences between samples [7, p. 6].

A copy of the scale as it appeared in the questionnaire is shown in Figure 1. Sample numbers (from a table of random digits) were recorded above each scale. The consumer then recorded his decision in the column corresponding to his cup number.

The Hedonic scale has excellent analytical characteristics. The results are similar whether one uses integers or the true scale values [11, p. 9],

Figure 1. Nine-point Hedonic rating scale

No.__________	No.__________	No.__________

Dislike	Dislike	Dislike
Moderately	Moderately	Moderately
Dislike	Dislike	Dislike
Very Much	Very Much	Very Much
Dislike	Dislike	Dislike
Extremely	Extremely	Extremely

which means that all modern statistical techniques can be used during analysis.

The reliability (reproducibility of results) of the scale is excellent. Quoting Peryam and Pilgrim, "Good reproducibility, well within statistically estimated limits, is usually found when the same food items have been tested repeatedly under the same conditions" [11, p. 11].

The Merck method was used for data analysis. The method involves calculating the fiducial limits for the control sample. This is a statistical method for determining whether or not the panels' average scores for the test samples are significantly different from the average score of the control sample. The fiducial limits represent a range of average scores (above and below average score for the control) within which an average score for a particular sample is *not* significantly different from the control. Average scores above or below the fiducial limits *are* significantly different from the control sample [7, p. 13].

Rank order relationships were used to determine the significance of preferences regarding the ranking of the whole, filled, and synthetic milks. Kendall's coefficient of concordance was used to determine the general agreement existing among consumers in their rankings of the three products. The F test was used to determine whether a significant concordance exists. If the observed F was larger than the tabulated F value, then, statistically, the ranks showed agreement.

Analysis of Data

The null hypotheses were stated as follows: $H_0 1$: There is no difference between whole milk scores and filled milk scores. $H_0 2$: There is no difference between whole milk scores and synthetic milk scores. $H_0 3$: There is no difference between filled milk scores and synthetic milk scores.

The Hedonic Rating Scale was given values from 1 (like extremely) to 9 (dislike extremely). The mean rating for whole milk was 3.18. The mean rating for filled milk was 2.90, while the mean rating for synthetic milk was 6.07. (See Figure 1 for description of numerical levels.)

Using the Merck method of analysis, at the 5 percent level of significance, whole milk scores were not significantly different from filled milk scores. However, synthetic milk scores were significantly different at the 5 percent level when compared with both whole and filled milk. In the eyes of the consumers, there was no measurable preference for either filled or whole milk.

The *F* test revealed that there was a statistical significance among the 140 consumers' rankings. The coefficient of concordance was calculated to be .877 revealing a high level of concordance. The analysis acknowledged a high degree of agreement among consumers with respect to ranking of the three beverages.

The rankings appear in Table 2. It is important to note that 63 consumers (45 percent) ranked filled milk above whole milk. Thirty-eight consumers (27 percent) placed filled milk and whole milk equally, while 36 consumers (slightly over 25 percent) ranked whole milk above filled milk. Also important is the fact that 99 consumers (approximately 71 percent) ranked synthetic milk last, while only 20 consumers (14 percent) ranked it first.

Summary and Conclusion

On the basis of consumer preference, filled milk has the capability to compete with whole milk. However, the success of filled milk in capturing part of the fluid milk market depends on the extent of merchandising used by the milk industry and the manufacturers of the filled milk product.

Schwartz stated that the "consumers' main criteria for acceptability will be taste" [2, p. 14]. However, he also concluded that what was needed for successfully marketing a filled milk product was a "creative merchandising policy—stressing perceived positives. Hetrick stated that much of the failure of filled milk to make market inroads in the Midwest was due to "the lack of consumer awareness of the product after 13 months of exposure . . ." [4, p. 2].

Table 2. Number and percent of consumers ranking milk products in various ways

Order of rankings[a]			Consumers	
1st	2nd	3rd	Number	Percent
W	F	S	23	16.43
W	S	F	4	2.85
F	W	S	45	32.14
F	S	W	2	1.43
S	W	F	6	4.28
S	F	W	7	5.00
1st	2nd[b]			
F and W	S		31	22.14
S	F and W		7	5.00
W and S	F		—	—
F	W and S		6	4.28
F and S	W		3	2.14
W	F and S		3	2.14
1st[c]				
W, F, and S			3	2.14
Total			140	99.97[d]

[a] W is whole milk, F is filled milk, and S is synthetic milk.
[b] The rankings were shortened to 2 because of ties in ranking.
[c] This category includes consumers who were unable to express any preference among the three products.
[d] Total does not add up to 100 percent due to rounding.

Both Hetrick [4, p. 5] and Schwartz [12, p. 14] state that flavor and merchandising policies are important to filled milk success. Based on the result of this study, it is the contention of this author that the key to the success of filled milk has become the merchandising policy alone, because there is no significant difference in preferences for filled milk and whole milk.

This study has concluded only, on the basis of taste, that there appears to be no difference in preference for whole milk or filled milk. However, consumers do have a preference for filled and whole milk over synthetic milk. Based on the current milk pricing plan, filled milk has a definite cost advantage over whole milk. If the aforementioned advertising and merchandising policy is applied in the sale of filled milk, the fluid milk market may be in trouble.

It seems that some adjustments may be called for in milk pricing to meet the price advantage held by vegetable fat. One possibility is to lower the fat differential for milk fat. Another more extreme alternative is to price milk as a beverage with no differential paid on butterfat.

The filled milk potential may also have an effect on the nonfat milk solids market. As noted in Table 1, if nonfat dry milk is used in the production of filled milk, an additional 5.8 cents advantage of filled milk over whole milk is attainable. A recent USDA recommended decision states, "Reconstituted skim milk in filled milk disposed of for fluid consumption should be treated as Class I milk" [18, p. 6].

It appears, then, that changes in pricing of milk solids may be used to combat the threat of filled milk. However, if the synthetic milk should eliminate some of the apparent taste problems noted by consumers in this study, the fluid milk market may be in for additional problems.

AMERICAN
AGRICULTURAL ECONOMICS ASSOCIATION
REPORTS AND MINUTES
1968–69

REPORT OF THE PRESIDENT

Your outgoing Executive Board is the first to operate under the new form of organization developed in the administration of Lawrence Witt and tooled during Ed Bishop's term of office. The membership of the Association is now represented more broadly on the Executive Board, and continuity is provided by electing directors for three-year terms.

Many of the activities that have commanded our attention during the last 12 months were initiated by the enterprising officers who preceded us. It has been our good fortune to move forward on several important fronts. Ranking high is the project for retrieval of literature, guided by Fred Abel and his committee. The Economic Research Service and Statistical Reporting Service are providing assistance whereby the National Agricultural Library will soon begin to produce tapes of bibliographic documentation of current publications in agricultural economics. The AAEA will then convert the tape to a printed publication for distribution. Moreover, the Library's computerized record will thereupon be available for literature retrieval.

This service only codes and retrieves titles. The exciting prospect seen for the future is electronic reproduction of the sources themselves. How soon will we be able to dial a number and have the pages of a book or report flash on a screen before us? I have asked Fred Abel's group to stay in touch with developments and keep us informed.

In the same broad category is the work to commission a series of review articles for publication in special issues of the Journal. Solid progress is being recorded and much credit is due Lee Martin and his co-workers.

One of the principles now built into our organization, thanks to Witt, Learn, and Harl, is to pull our various activities into more closely knit groups. One such area of work, titled professional activities, is headed by Jim Hildreth. As an example of thinking and planning that have been going on, Ron Aines and his industry committee are looking into the possibility of professional interchange between industry and universities or government. Several other proposals for professional action will become an operating reality in the Hathaway administration.

Likewise, more than before, all awards activities are being directed by an awards chairman, who this past year has been Emery Castle. He and his subchairmen (Schuh, Eicher, Nelson, Timm, and Pulver) conduct one of the significant undertakings of the AAEA. It is worth noting that the awards committees took special pains to be sure that various areas of research or extension would be equally eligible for award.

Among unsung heroes of our organization are the members of the student affairs committee chaired by Ken Boggs. The undergraduate student program is an action program and it demands time and effort from the committee. Our gratitude is owed. In addition, Neil Harl and Ray Beneke have worked with Boggs in setting up more formal organization for undergraduate activities.

Another time-consuming program is that of contributed papers. Milton Manuel and his associates did the fine job that has come to be expected. Participation has been excellent.

We must note the dedicated service that Del Kearl has given our organization for 10 years. The editor, Varden Fuller, and his assistants and the editorial council are vital to our organization. Out of personal gratitude but on behalf of the Association as well, I record my thanks to the hosts last winter and this summer, Gene Hamilton and John Redman and their associates.

Joe Ackerman dare not be left anonymous in these credits. He has been a sturdy pillar for many years. This year he was chairman of both the fellows election committee and the joint ASA-AAEA statistical committee. In the latter regard, we have taken steps to make the statistical committee a more active one. In few subjects have agricultural economists a deeper interest than in preserving a flow of reliable statistics of agriculture and of the economy. Henceforth, the statistical committee will involve itself more actively than in the past.

Vernon Ruttan has brought imaginative thinking to our international field. Dick McConnen headed a useful study of our employment service.

More important than spotlighting activities of the past is to suggest ideas for policy for the future. My final presidential letter presents four suggestions, which for the record are to continue such a letter and move to it some of the miscellaneous notes of passing interest now carried in the Journal; to keep an open mind on the best mission of the Journal; to express ourselves in the political sphere on matters of direct concern to us; and to end the appearance of democracy without the substance that characterizes our present method of selecting the president-elect of our Association.

To these I add just a couple. On few subjects do our members, diverse though they be, have a more common interest than in the statistical base for our discipline. Having charged the statistics committee with more responsibility, I urge that the Association address itself more forcefully to the subject.

As we grow in size and comprehensiveness, we must reconsider our best mission and *modus operandi*. Whether we are concerned for the content of the Journal, the composition of our annual program, or the activities we carry on throughout the year, in all cases we must face the fact that there is a finite limit on what we can undertake directly on behalf of our membership but infinite possibilities on what we can aid, facilitate, encourage, and support. We can sponsor or co-sponsor, we can serve as common meeting ground, we can be catalyst one time and crucible the next. As illustrative examples, we could sponsor a teaching symposium or bring teachers of one subject area together to consider problems of texts or other teaching materials or even to thresh over issues in subject matter content. We could set up a session on the relation of the agribusiness and academic parts of our profession.

Finally, I dare to advise that our leaders must ever strive for a balance between meeting the particular needs of our specialty sub-groups and cultivating the area of our common interests. I am as sensitive as anyone, I believe, to the interests of our several constituencies, but I also believe there must be and is a common denominator; and it is something to be maximized. To change the figure, we must avoid divisiveness and parochialism.

I am grateful for the opportunity you gave me to serve as your president.

Respectfully submitted,
HAROLD F. BREIMYER

RESOLUTION

The University of Kentucky, its president, and the faculty and staff of the Department of Agricultural Economics have shown much hospitality to the members of the American Agricultural Economics Association, their families and guests, and to the AAEA officials and related groups at the Annual Meeting held at Lexington, Kentucky, August 17-20, 1969. *Therefore:*

Be it resolved that the American Agricultural Economics Association express its sincere gratitude to President Otis Singletary and to the faculty and staff of the Department of Agricultural Economics and their wives for their hospitality. All these, under the leadership of John Redman, Bob Rudd, and Milt Shuffett of the Local Arrangements Committee, have served us efficiently and graciously. The Association wishes to acknowledge the individual effort of Miss Gertrude Hanly for her art display on the cover of the program, the materials packet, and elsewhere.

Be it further resolved that a copy of this resolution be sent to President Singletary, to Dr. Redman, to each of his subcommittee chairmen, to Miss Hanly, and to others at the University of Kentucky as appropriate.

REPORT OF THE SECRETARY-TREASURER

In 1968 there were 4,117 individual members of the American Agricultural Economics Association (Table 1). This compares with 4,141 individual members for the previous year. Although the number of regular members was up slightly, other categories of individual membership were down in 1968. The decrease in the total number of individual memberships was the first to occur since 1952.

By contrast, there were 38 sustaining members in 1968 and 29 in 1967. The subscriptions, too, were up with 1,618 in 1968 and 1,481 in 1967. Two-thirds of the increase was in foreign subscriptions.

Table 1. American Agricultural Economics Association: number of members and subscribers, 1968

Category	Number
Sustaining members	38
Regular members—United States	2,716
Foreign	547
Junior members—United States	585
Foreign	82
Corresponding members	187
Libraries and businesses—United States	594
Foreign	1,024
Exchange	3
Number of copies AJAE	5,776

Financially too, this report is not as favorable as it should be. In 1968 the Association had an operating loss of $7,479.09 (Table 2). Since this report is

Net operating loss			7,479.09

the first to be made on a calendar year it is not possible to make comparisons with previous experience for a directly comparable period. However, the income for calendar (and fiscal) year 1968 was $78,497.08, or $2,271.24 above that for the July 1, 1966 to June 30, 1967 period.

Expenses for 1968, on the other hand, were $85,976.17, or $18,060.05 higher; and, whereas the Association showed a gain of $8,309.72 in the 1966-67 period, there was the substantial loss noted above in calendar 1968.

The biggest difference between the periods was a $9,091.25 higher Journal printing bill. Part of this was because of increased printing rates but also part was because of the larger number of pages printed.

Yet another item that added to the high expenses for 1968 was the overlap of editors during the last half of the year. The support of these two offices, even though the "old" editor was phasing out and had reduced expenses, resulted in the outlay for that activity of AAEA being $5,280.55 more in 1968 than in the earlier period.

Also, whereas the past policy of the Association has been not to pay travel expenses for its committees, there has been some bending of this policy and the committee expense in 1968 was above that for the earlier period. In 1968 the committee expenditures were $6,554.68 (Table 3). This includes the awards program activities.

Table 3. American Agricultural Economics Association: committee expenditures, 1968

Membership—Postage, printing, etc.	$ 52.26
Fellows—Travel	190.56
Retrieval of Literature—Travel	1,036.24
Sustaining Membership—Postage, printing, etc.	32.63
Review of Postwar Work in Agricultural Economics—Travel	1,205.29
Awards—Postage, printing, etc.	149.55
Research Awards	2,050.02
Teaching Awards	250.00
Extension Awards	500.00
Undergraduate Affairs—Postage, printing, etc.	288.13
Honoraria	200.00
Awards	600.00
Total	$6,554.68

Higher wages and higher stationery and supply bills—just plain higher cost of living—also added to the deficit.

Obviously, the Association cannot continue to operate with a net loss, and action must be taken to correct the situation.

There is little hope that great reductions can be made in our operating costs. Future printing bills are likely to continue to be high, because printing costs will not go down and probably will go even higher. Some savings in connection with the editor's office will come next year because we will not have a "double" editor expense. However, costs of operating the office of editor and secretary-treasurer will go up as wages and prices increase and as the volume of business done by those offices increases. The committee expense can increase or decrease, depending on how the Executive Board "bends" or alters the Association policy.

All of this means that costs are going to continue to be high. They may not be as high as they were in 1968 but they will be high. The editor may be instructed to print smaller volumes of the *AJAE*, committee expenses may not be authorized, and/or less support may be authorized for the editor and secretary-treasurer. These and other actions may be taken to reduce our operating costs.

To help on the other side of the account, we can make efforts to increase our income. As mentioned earlier, we had a decrease in 1968 in individual memberships in the Association. Over the previous 16 years the average increase has been 157 members per year. One way of meeting our rising expenses is to have a continued growth in membership.

If the expenses cannot be controlled sufficiently or if income from the growth in memberships is not great enough, the Association will be forced to increase its dues rates. These are among the lowest for professional associations and have been increased only $1.00 since 1958. During this time we have expanded our activities, and our costs of all operations have gone up. The printing bill for the *JFE* in 1958 was $27,078.74, as contrasted with this year's bill of $50,577.87 for the *AJAE*.

The Association is not bankrupt. The net worth, with investments at cost, was $51,351.11 at the end of the year (Table 4). With stocks and bonds at market value, the Association's net worth was about $144,932. However, $50,000 of this has been committed for the initial support of the Agricultural Economics Documentation Center.

Table 4. American Agricultural Economics Association: balance sheet, December 31, 1968

Assets			
Cash			$ 1,658.26
Dividends to be remitted by E. F. Hutton Co.			171.90

Investments (at cost)—			
Corporation bonds		$22,936.91	
Listed stocks		64,627.98	
(Market value approximately $181,147)			87,564.89
Total			$91,262.05
Liabilities			
Editor's assistance payable			$ 145.00
Editor's postage payable			13.20
Editor's travel payable			274.21
Due Cornell for secretarial assistance			4,931.61
Prepaid membership dues			14,922.00
IRS Taxes due			113.00
Printing cost of December AJAE			19,511.92
			$39,910.94
Net Worth			
Balance December 31, 1967	$58,830.20		
Plus: Net operating loss	7,479.09		
Balance December 31, 1968			$51,351.11
Total			$91,262.05

The Association is sound financially because of its endowment fund but steps must be taken to bring expenses and income in balance if it is to continue to have this sound financial status.

Respectfully presented,
C. D. KEARL, *Secretary-Treasurer*

AUDIT REPORT

Dr. Harold F. Breimyer, President
American Agricultural Economics Association
200 Mumford Hall
University of Missouri
Columbia, Missouri 65201

Dear Harold:

As you requested in your letter of November 5, we conducted the annual audit of AAEA recently. Dr. C. W. Loomis was kind enough to serve on the committee with me.

We have examined the financial records of the American Agricultural Economics Association as of December 31, 1968.

As a part of this examination, we selectively reviewed income and expenses for the fiscal year, inspected the checking account, confirmed the reported inventory of the securities held by the Association, and randomly tested the record of membership against payment of dues. Related aspects of the financial affairs of the Association also were reviewed.

We found the financial records to be correct and to fairly represent the financial position of the Association on December 31, 1968.

Sincerely,
DANA C. GOODRICH, JR.
Associate Professor of Marketing
Cornell University

REPORT OF THE INVESTMENT COMMITTEE

There were no changes during 1968 in the stock and bond holdings of the American Agricultural Economics Association. The stocks, however, moved up in market value by almost $20,000 (Table 1).

The dividends for the year, $5,480.49, amounted to a return of 3.8 percent on the value of the stocks at the beginning of the year. The bonds returned $1,112.54 in interest and this, on the value at the beginning of the year, was a return of 6.0 percent. Short-term investment of operating funds brought the Association $133.33.

Not all of the stocks showed increases in market value (Table 2). The Borden and General Electric declined. Chase Manhattan Bank, Clark Equipment, Continental Can and Jewel Co. showed the greatest relative market advances of those held by the Association.

The highest dividend rates were paid by American Tel. and Tel., Clark Equipment, Commonwealth Edison Co., Continental Can, Jewel Co., and Standard Oil, New Jersey.

Bonds provide a stable return on the investment but fall in value as interest rates increase. During the year the AAEA bonds provided $1,112.54 of income but declined in market value by about $625 (Table 3).

Witco Chemical Co.	2,040.00	1,640.00	100.00	2,000.00	6/1/80
Total	$22,936.91	$18,040.00	$1,112.54	$22,000.00	

Overall, the investments provided $6,726.36 in cash dividends and interest to help finance the various Association activities.

Prepared by C. D. KEARL
for the committee

REPORT OF THE EDITOR

In the year ending June 30, 1969, new manuscript submissions were 268. This is up 30 percent from the previous 3-year average. My immediate predecessors, Earl Swanson and James Nielson, reported acceptance rates of 44 and 46 percent, respectively. It is too early to know if so high an acceptance rate can be maintained with respect to a higher level of submissions.

I believe it is worthwhile that our members be aware of a few details on the JOURNAL's magnitudes and how they come about. Most JOURNAL-watchers will know that the papers emerging from the winter and annual meeting programs are not refereed and that the acceptance rate is automatically 100 percent. Parenthetically, it should be noted that the proceedings papers are not included in the calculation of the acceptance rates. The Editor's only role with respect to the aggregate magnitude of the proceedings papers is to join the President in prescribing and exhorting conciseness on the part of the participants he invites.

As an average for 1960-1968, the Proceedings of the Annual Meeting (December issues), including the program and Association reports, have taken up 40 percent of the JOURNAL's total pages. Winter proceedings papers (carried in the May issue) have taken 7 percent. The remainder, 53 percent, has been the Editor's nominal province for refereed articles, communications, news notes, and announcements. Since the line of admonishment to constrain the printing bill usually runs from President to Editor and not vice versa, there may be a moral somewhere in these percentages.

A few supporting and related statistics on the JOURNAL's magnitudes, 1960-1968, are given in Table 1. These figures do not suggest much in the way of trends or consistent patterns. I find the low correlation between pages and items somewhat surprising. One notes that in 1960, 1,653 pages were enough to handle 191 items, whereas in 1968 it took 1,836 pages for 193 items. Does this imply creeping verbosity? Several other couplets can be picked from the series that seem to support this implication.

Table 1. Pages and items published by *AJAE* (*JFE*), 1960-1968

Year	Pages of edited papers[a]	Pages of proceedings papers[b]			Journal, total pages	Number of items[c]
		Winter meeting	Annual meeting	Total		
1960	775	93	595	688	1,563	191
1961	863	143	589	732	1,595	219
1962	1,071	173	683	756	1,827	222
1963	811	127	629	756	1,567	209
1964	846	68	559	627	1,473	166
1965	964	114	569	683	1,647	167
1966	919	157	684	841	1,760	205
1967	915	83	642	725	1,640	191
1968	998	102	736	838	1,836	193
Average	909	117	630	747	1,656	199
Percent	53	7	40	47	100	

[a] Includes articles, communications, book reviews, and news notes.

[b] Includes invited papers, discussions, and association reports.

[c] Edited papers and proceedings papers including communications, replies, and discussions; book reviews, news notes, and association reports are not included.

Creeping or not, I believe we are afflicted with verbosity and that we can get better mileage from our printed pages. My persuasion to this view comes mainly from the reviewers of manuscripts who so characteristically recommend reduction by eliminating unnecessary material and editing for concise communication and from not too fruitful experience in trying to persuade authors to do as reviewers recommend.

In the August issue, we introduced a *Research Notes* section that we hope will help to promote more effective use of our printed pages. The same issue has an Editor's *Communication* that explains the purposes of *Research Notes*; also, it explains the economy we have attained in *News Notes*.

A rigid length limitation on manuscripts that are to be refereed is undesirable, I believe. Yet, since the JOURNAL is truly a participatory enterprise in terms of both magnitude and quality, it seems proper to suggest that contributors should ask themselves the counterpart of the erstwhile wartime question: "Is this trip really necessary?" This question could apply to the whole paper as well as its components.

I have the pleasure of announcing that Gerald Dean has become Associate Editor to serve concurrently with Harold Carter and myself.

The devotion and geniality of staff associates and Editorial Council are noted with much gratitude. With no less gratitude and with some wonderment of their unselfishness, I acknowledge the immeasurably significant contribution of countless manuscript reviewers whose compensation is principally the privilege of electing anonymity. The reason for saying "countless" is that many reviewers note that they have consulted colleagues, but they do not always say how many.

VARDEN FULLER, *Editor*

MEMBERSHIP COMMITTEE REPORT

Members of the committee include Quentin M. West, Chairman; Fred H. Wiegmann; T. T. Williams; Charles R. Pugh; LaVon S. Fife; N. Keith Roberts and Del Mar Kearl. We were a little late in getting under way due in part to the necessity of forming a new complete committee and the chairman's foreign travel during the latter part of 1968. After contacting former chairmen to learn what activities had been successful in the past and receiving suggestions from other members of the Membership Committee, the chairman met with Del Kearl in February to draw up a plan of action.

Responsibility was divided as follows:

West—Agricultural economists in the Federal government and foreign members.

Fife—Agricultural economists in business and industry.

Roberts—Agricultural economists in colleges and universities in the western states.

Pugh—Agricultural economists in colleges and universities in the north central states.

Wiegmann—Agricultural economists in colleges and universities in the eastern states.

Williams—Agricultural economists in colleges and universities in the southern states.

Each member of the committee was to write the chairman of the agricultural economics department of each land-grant university and request the following assistance in membership activities:

a. Appoint a staff member, or himself, as University contact for AAEA membership drive. If the Extension Service is separate, ask him to propose a contact in the Extension Service.
b. Request this Membership Contact to determine who are members among the faculty and graduate students and who are not. Ask him to give nonmembers a copy of a letter from President Breimyer outlining the advantages of membership in the AAEA and give them an application form.
c. Ask that a notice about AAEA membership, and where to send dues, be put in the Department's News Notes which are sent annually to alumni.
d. If the Department does not have News Notes, ask about their willingness to circulate information among their alumni about AAEA membership.
e. Encourage establishment of Junior AAEA chapters at the universities.
f. Request a list of other colleges or universities in the state which are giving degrees in agricultural economics.
g. Request information on chapters of agricultural clubs similar to those in the Chicago and San Francisco areas. Send this information to Fife.

Upon obtaining information on other colleges and universities that give degrees in agricultural economics, they were to write these institutions with similar requests.

They have been requested to write each of these university membership contacts in September 1969 repeating much of the above requests but asking that a special effort be made with incoming graduate students.

All members of the committee made the contacts as requested. Apparently, they have received cooperation. Administrators and division directors in the Federal government were very cooperative in passing this information on to their agricultural economist colleagues.

There were some suggestions for stimulating membership that would require action by the Executive Committee. The Chairman submitted these to President Breimyer, and these are listed for your consideration:

a. There is no provision for undergraduate students being affiliated with the Association, yet there is some participation at the annual meetings in the form of student debates. If these students could be affiliated during their junior or senior years, we think it would be conducive to continue membership, especially for those who do not go beyond their B.S. degree. Therefore, we propose a Student Membership (differing from the Junior Membership) with a fee of $2.00. This would entitle them to a membership card, AAEA notices, and one subscription to the Journal for each 10 student members. Local chapters may be organized which may, or may not, be tied to the Junior Chapters where they now exist.
b. A student section in the JOURNAL for graduate student contributions may encourage activity of our junior members.
c. The handbook has always been an inducement for membership. It might be helpful if this were updated annually by including, in one issue of the JOURNAL, similar information on new members.
d. It might ease the load of the annual membership drive if members were encouraged to pay dues for two or three years with a small reduction in cost.

Other activities by the Membership Committee are as follows:
a. The secretary sent a note to the heads of departments in September regarding junior members and a supply of application forms.
b. A dues reminder was included in the secretary's letter to all members in November.
c. Dues notices were sent out in January.
d. In July the chairman and the secretary sent a letter of encouragement to all delinquent members.

The time is too short to determine if the efforts of the Membership Committee will be successful. As of July 1969, we had 150 fewer members than at the end of 1968. (678 delinquent members were cut off on that date.) All of this net loss was in junior members and foreign members. Regular U.S. members have increased slightly. The number of junior members has been decreasing since 1967. I am not sure whether this is indicative of less interest on the part of graduate students or fewer graduate students in agricultural economics.

The number of foreign members has decreased somewhat in total, but more important is the percentage turnover. Thirty percent of the delinquent members as of July 1969 were foreign members, and this represented 37 percent of the foreign membership; 63 percent of the delinquent institutions were also in foreign countries.

A large part of the foreign membership results from the practice of the Agency of International Development to finance three-year memberships in a professional organization for each of the trainees who come to the United States. At the end of the three years, a large part do not continue membership. I have discussed this problem with representatives of other professional associations and they have had the same experience. Ten dollars represents a lot of money for most young foreign economists, and it is very difficult in many countries to obtain U.S. dollars. What action should be taken depends to a large extent on how interested AAEA is in maintaining foreign members. Should they be given a discount that would just cover the marginal cost of supplying them with the JOURNAL? One possibility is to allow them to pay for membership with

UN chits which can be purchased at the local UN Office; then AAEA could redeem them at the UN Office in New York.

QUENTIN M. WEST, *Chairman*

REPORT OF THE SUSTAINING MEMBERSHIP COMMITTEE

There are now 45 Sustaining Members of AAEA for 1969. The members of the Sustaining Membership Committee have been helpful and cooperative. This is much appreciated.

The 1969 Sustaining Members are:

Agway, Inc.
Allied Mills, Inc.
American Dry Milk Inst., Inc.
Beatrice Foods Co.
Board of Trade of the City of Chicago
Brown & Williamson Tobacco Corp.
Campbell Soup Co.
Cargill Incorporated
Central National Bank in Chicago
Central Soya Company, Inc.
Chicago Mercantile Exchange
Continental Grain Company
Cotton Producers Association
Dairymen's League Coop. Assn., Inc.
Deere & Company
Doane Agricultural Service, Inc.
Eastern Milk Producers Corp. Assn., Inc.
Farm Journal, Inc.
Farmers Union Central Exchange
Farmland Industries, Inc.
F. S. Services, Inc.
Geo. A. Hormel & Co.
Green Giant Co.
The Harvest Publishing Co.
H. P. Hood & Sons, Inc.
Indiana Farm Bureau Coop. Assn.
International Harvester Co.
The Kroger Company
Land O'Lakes Creameries, Inc.
Merck & Co., Inc.
Kraft Food Division
Northwestern Mutual Life Ins. Co.
Oscar Mayer & Co.
Peavey Company
Pioneer Hi-Bred Corn Co.
The Progressive Farmer
Ralston Purina Company
Register & Tribune
Safeway Stores, Incorporated
Soy-Cot Sales, Inc.
Staple Cotton Coop. Assn.
The Travelers Ins. Company
Weitz-Hettelsater Engineers
Wilson & Co., Inc.

C. D. KEARL, *Chairman*

REPORT OF THE INDUSTRY COMMITTEE

The Industry Committee has carried on three major activities during the year: (1) planned for the annual industry dinner; (2) worked with the newly created Professional Activities Committee; and (3) evaluated alternative types of exchange activities that the Association could sponsor to increase beneficial interchange between industry and nonindustry economists.

Plans are complete for the Sixth Annual Industry Dinner to be held as part of the annual AAEA meetings at Lexington, Kentucky. Robert Eggert, Staff Vice President of Economic Research for RCA is to present a paper, "Business Searches for Relevant Economic Inputs." The dinner is being publicized in trade publications to encourage more industry economists to attend and join AAEA.

The chairman of the Industry Committee, by virtue of this position, is a member of the newly created Professional Activities Committee and has attended its meetings; and the committees have worked together on questions such as interchange and recruitment.

The subject of increased interchange divides itself into two major parts: (I) types of exchange activities that are feasible; and (II) how the AAEA could implement increased exchange. The need for this evaluation arises from the tendency for industry economists and the remainder of the agricultural economics profession to become isolated from each other. Yet agribusiness is a major customer for the output of the profession in the form of data, analysis, projections and trained people. Increased interchange should help improve the product and customer relations.

I. Types of Feasible Exchange Activities

Following considerable discussion and evaluation the realistic opportunities for increased exchange between industry and nonindustry economists seem to be:

1. workshops
2. seminars
3. visiting lecturers, speakers, consultants
4. sabbatical leave exchange
5. advisory planning committees that emphasize the future planning function (not review) for research and training programs
6. membership on graduate committees.

II. How the AAEA Could Implement Increased Exchange

1. Workshops, forums, or seminars (1 to 3 days in length) that include a good mix of industry and nonindustry economists on a "pertinent major macroeconomic issue," have been suggested from several sources. The AAEA could set up one or more a year at the USDA, an adjustment center, or a company location.
2. The AAEA could develop a list of industry economists who are interested and available for seminars or as visiting lecturers. This could include both active and retired industry economists.
3. Good programs that outstanding agricultural economics departments or industry research divisions already have in existence that result in good interchange between industry and nonindustry economists could be systematically identified and publicized to other departments and throughout the profession.
4. Research and training advisory planning committees could be organized by the Association, one for each region of the country, to include an appropriate mix of industry and nonindustry economists to work with government, academic, and industry departments in the future planning function for research and training programs.

The committee has developed a highly imperfect list of AAEA member industry economists. When another survey of agricultural economists is made for an updating of the Association Handbook (updating is needed now), the committee would like to cooperate to develop a better list of industry economists. Such a list is valuable for research and identification of professional needs and as a service function to the Association officers and the Industry Committee in soliciting assistance in Association activities.

R. O. AINES, *Chairman*

THE REPORT OF THE AWARDS COMMITTEE

This is the second year that the AAEA awards have been coordinated by one chairman. While I am not fully informed regarding operation of the program under the earlier arrangement, I believe the present system is working reasonably well. A consolidated announcement and uniform types of recognition have obvious advantages. The following items characterize the current year's experience:

1. In some categories there was a substantially larger number of entries than a year ago. In the published research category there were 41 entries, compared to 19 a year ago. In the M.S. thesis contest 44 theses were judged, which was an increase from a year ago. In the Ph.D. thesis category, there were 33 entries. Entries in the teaching and extension categories were 14 and 7, respectively. The reading was certainly substantial in all of the research categories.

2. No serious problems were encountered in interpreting the rules. In two categories the entry deadline was not met. We refused to judge the late entries in both cases but suggested they might wish to consider presenting the entry to next year's subcommittee. This was suggested in the belief that the rules were formulated to assist with the judging, rather than to preclude any worthy item from being considered. In the case of one published research winner, the publication carries a 1967 publication date. However, the work did not actually see the light of day until 1968, and the entry was ruled by me to be eligible.

3. There are two serious problems pertaining to the Awards Program. These are:

   a. The number of entries in the undergraduate teaching and the extension categories. The Association may wish to consider limiting the number of extension awards to one, unless the number of entries exceeds (say) 10. In any case, these subcommittee chairmen will be encouraged to stimulate entries next year.

   b. The exceedingly heavy load of reading and complicated logistics associated with the research categories is making it increasingly difficult to be ready for these meetings. We will probably require receipt of all entries by February 15 next year. This will make it necessary to mail announcements earlier than has been the case. I recommend strongly that President-Elect Hillman select his Awards chairman and subcommittee chairmen far enough in advance of next summer's annual meeting so that they can meet during the annual meetings if they desire.

4. Question has been raised by the published research subcommittee as to whether books and long bulletins should be judged in competition with journal articles and shorter publications. We have no recommendation for change, as the arguments in favor of keeping the present system appear to be stronger than those favoring change at this time.

5. The Ph.D. subcommittee had the most difficulty in completing their judging prior to these meetings. Their suggestions are:

   a. Start the judging on February 15 rather than March 15 (referred to above).

   b. Require each university to submit three rather than two copies.

   c. Allow universities to submit one thesis for every 12 completed, instead of one for every 8. A difference of opinion exists on the subcommittee with respect to the latter recommendation, and some would prefer to increase the number of judges rather than change the ratio. The masters thesis subcommittee chairman also recommended that the ratio be changed from 1 to 12 or 15, instead of the present 1 to 8.

It appears to me that the above is a policy issue, and a decision should be made by the Executive Board. I am inclined to recommend the Ph.D. ratio remain as it is, but that the number of judges be increased to 12 instead of 6. Not only will this spread the work, but it will also permit better balance on the committee. I am also recommending that the M.S. ratio be changed from the present 1 to 8 to 1 to 12.

6. Warren Bailey has made a suggestion relative to the Ph.D. winners as well as other published research winners. It would seem this is a matter that should, at a minimum, involve the Editor and possibly the Editorial Council. As far as the Awards Committee is concerned, we would be pleased to see this added recognition and evaluation of the research. It has also been suggested that a description of the winning extension programs also be included in the Journal.

7. Carl Eicher, Ph.D. thesis subcommittee chairman, has identified what may be a potentially explosive issue. This pertains to a workable definition of "agricultural economics." The number of eligible theses from a particular institution affects the number that may be submitted. The eligibility of research, teaching, or extension activity is also involved. The matter has only recently arisen, and I have no particular recommendation to make except that the Executive Committee should give the matter immediate attention. Perhaps a special committee should be appointed to study the matter and make recommendations.

Finally, I would emphasize a point I made last year. The Awards Committee is a judging and administrative group. It is exceedingly difficult for this group to identify and evaluate policy issues connected with the Awards Program. Therefore, if the Executive Board wishes awards policy to be studied at any time, it is recommended that a separate group be appointed to do that. President Hathaway has asked that I serve an additional year as chairman, and I have agreed. However, it would be inappropriate for me to serve longer, even if President-Elect Hillman would wish for me to do so, which I doubt. Prior to serving as chairman, I was a M.S. thesis judge and subcommittee chairman for published research. In my final report to the Executive Board a year from now, I intend to prepare an evaluation of the entire Awards Program. It is apparent the program is requiring substantial resources to carry it forward. It may be helpful for someone to attempt to identify the benefits and costs, both implicit and explicit, of the present Awards Program.

Emery Castle, *Chairman*

Award Winners

Distinguished Extension Program

Gene McMurty, Virginia Polytechnic Institute
Noah S. Hadley, Purdue University

Distinguished Undergraduate Teacher

Albert H. Harrington, Washington State University

Master's Thesis

REPORT OF THE STUDENT AFFAIRS COMMITTEE

This is the twenty-first year that a Student Section has operated as part of the annual meeting of this Association. This year we have 47 chartered chapters (local departmental clubs) of the Student Section. We have chartered three new clubs this year: Tuskegee Institute, the University of Nevada, and the University of Manitoba. In addition, there are several non-chartered schools usually represented at each annual meeting. We have encouraged participation and involvement of all schools offering courses in agricultural economics in the Student Section program and at our annual meetings.

The 47 chartered chapters may be classified as follows:

Canada	United States and Possessions	
Number of schools	Number of schools	
	Land-grant	4 year non-land-grant
4 Ontario Agricultural College MacDonald College University of Alberta	36	6 Texas Technological College Southern Illinois University A&T College of North Carolina Tennessee Technological University Tuskegee Institute

Typically about one-half of the chartered chapters are represented at our annual meetings and contests, with about 50 to 100 students present and participating in some way, either in the Student Section program or attending the meetings of the AAEA.

As indicated in prior annual reports, individual students have not established a continuous year to year attendance record in sufficient numbers to provide a core group about which the Student Section might function somewhat independently of the Student Affairs Committee. This has not deterred student officers at annual meetings from implementing programs which either are left uncompleted or must be kept alive and working by the Student Affairs Committee. This has been a continuing and expected fact of life for the committee, but it is a very important part of the somewhat frustrating and lonely feeling experienced by some of our student officers. The absence of funds for visible and realizable projects at the annual meetings has also added to this frustration.

As a result of action by the Student Section at Bozeman last August to assess a fee associated with a membership certificate (proposed as a prestige item at Guelph) and subsequent discovery of no specific AAEA Bylaws article pertaining directly to the Student Section, President Breimyer asked Neil Harl to chair a committee of three (Neil Harl, Ray Beneke, and Ken Boggs) to draft a proposal for an article to the AAEA Bylaws relating to Student Section activities. This proposal was presented to President Breimyer and circulated among members of the Student Affairs Committee for their comments and suggestions. Based on written comments from committee members and students, Neil Harl prepared a revised proposal. This revision, dated July 10, 1969, was recirculated to committee members and student officers prior to a meeting called for August 15, 1969, at Lexington. Six of the eight regular members and three of the four student officers were present at this meeting. Neil Harl recommended the proposal to be Article XIII of the AAEA Bylaws and to renumber the current Article XIII as Article XIV. The committee members and student officers present unanimously approved the proposed Article as presented.

Participation in these contests has tended to be fairly high. This year the number of schools represented was unchanged from 1968, but individual student participation declined. Repeat attendance by individual schools and indi-

* A total of 22 different colleges and universities were represented and 53 students were involved in our programs.

vidual students has been somewhat variable, depending in part on the location of the annual meetings. Some schools have consistently participated in these contests year after year—reflecting the dedicated service of our teachers and faculty to the young people of those institutions and to their Association.

The contest program has been a most successful effort. It has brought young people to the annual meeting of our professional association and offers them an opportunity to see and feel the professional nature of our chosen field. This is over and beyond the direct contribution of the contests themselves.

[a] Estimated.
[b] Proposed.

It has been a real honor for me to have served as chairman of this committee these past three years. Members of this committee have worked very hard to make the Student Section program a viable and integrated part of this annual meeting and to impart to students the professional nature of this Association. I personally want to thank all members of the committee, the coaches, faculty, and other members of this Association who really make this program effective by their personal contribution of time and effort. Without their support and the support of the Executive Committee, this program could not have achieved its present level of participation and success.

Respectfully submitted,
Ken B. Boggs, *Chairman*

REPORT OF THE POSTWAR REVIEW COMMITTEE

As a part of its continuing obligation to serve the profession, the American Agricultural Economics Association has committed itself to have prepared a series of review articles. Members of the Association and graduate students have long expressed a felt need for a more efficient means to bring and keep themselves up to date in the literature of the different fields of agricultural economics. Another stimulus has been the successful series of review articles supervised by the American Economic Association and the Royal Economic Society, and published in the *American Economic Review, Economic Journal,* and *Econometrica,* also as four volumes in hard covers. Serious efforts will be made to use the best of these review articles as models.

Another goal of the enterprise is to assist agricultural economists and graduate students in their search for professional identity. This will be done by summarizing the contributions agricultural economists have made to knowledge in the different fields.

In general, the review articles will for each problem area or subdiscipline, assist us in our efforts to bring ourselves up to date by outlining the nature of the field, including the underlying theory as well as analytical developments.

Past contributions to the field will be indicated. Serious efforts will be made in each review article to dramatize future challenges.

The attached outline is tentative and subject to change as detailed outlines are prepared for specific review articles. For the present, it is planned to review literature from extension economists along with the rest of the agricultural economics literature. In certain problem areas where extension has had a large role to play (farm management, marketing, and commercial farm policy, for example), extension's contributions may be treated in a separate section, according to the judgments of the collaborators on that chapter.

At this stage, the Literature Review Committee plans to proceed by asking qualified members of the profession to prepare brief outlines that would indicate how a different problem area or subdiscipline might be reviewed. The economist may report with what he believes would be the uniquely best organizing principle, or he may bring back to the Committee more than one alternative approach. No irrevocable commitment has been made to the outline that follows. In Agricultural Marketing, for example, Professor Helmberger may report with two strategies: an outline of one review article that would deal with the broad field of Agricultural Marketing and Consumption, and another set of outlines that would deal with each subfield (two or more) in greater depth.

A certain amount of duplication is unavoidable. In fact, it can be argued that only by some duplication can the interdependence among the different fields be shown adequately.

It should be made clear that a request to an economist for an initial outline carries no implication that the individual asked to prepare the initial outline will later be commissioned to prepare the review article. Initial outlines will be reviewed by the Review Committee and in some cases revised before the outlines become an element in the negotiations between the committee and prospective authors. Outlines approved by the Commmittee will not be binding on prospective authors, but they are likely to serve as a starting point for the negotiations with prospective authors.

The committee hopes to have a subcommittee for each chapter. The subcommittee might include the authors of the review article, qualified reviewers of the article, and a member of the Review Committee. The subcommittee would provide to the authors whatever guidance and assistance that are indicated. The representative of the Review Committee would provide the linkage between each subcommittee and the Review Committee, which would bear ultimate responsibility for overall coordination.

LEE R. MARTIN, *Chairman*

REPORT OF COMMITTEE ON LITERATURE RETRIEVAL

At the 1968 summer meeting of the American Agricultural Economics Association, the Committee on Retrieval of Agricultural Economics Literature recommended to the Association that it establish an American Agricultural Economics Documentation Center in conjunction with the National Agricultural Library and publish a bimonthly *American Bibliography of Agricultural Economics (ABAE)*.

The Board of Directors accepted the report and at the winter meeting decided to establish the Center. In July of 1969 the American Agricultural Economics Documentation Center was established. The National Agricultural Library (NAL), the Economic Research Service (ERS) and the Statistical Reporting Service (SRS) will assume full responsibility for financing the Center, but the Center will function to meet the needs of agricultural economists as specified by the Association.

This report describes in more detail the developments leading to the establishment of the Center, the need for and characteristics of the Documentation Center, and some descriptien of a broader literature retrieval system.

Historical Development

The Association's first official recognition of the literature retrieval problem was at the 1960 winter meeting. At that time the Association agreed to co-sponsor in conjunction with the Social Science Research Council, at SSRC's expense, a conference to discuss the literature retrieval problem.

Dr. Harry Trelogan organized the conference for the spring of 1961. It was attended by 11 librarians and 8 agricultural economists. They concluded that there was a problem and that it could be solved. They recommended, as a first step, that the Association appoint a committee to design and obtain funds for a study of the bibliography control of agricultural economics literature and the bibliographic needs of agricultural economists. It was emphasized at the meeting that the final product might be the creation of a special tool, the Bibliography of Agricultural Economics. It was also stressed that this project would strengthen the entire profession by the process of upgrading its tools.

President Nicholls appointed the "Committee on Retrieval of Agricultural Economics Literature" immediately after he received the conference report, June 1961. He obtained approval from the Executive Council by mail. He appointed Harry Trelogan (chairman), Bennett White, and H. G. Halcrow to the committee. Dr. Trelogan worked with the National Agricultural Library and prepared a project that was submitted to the National Science Foundaton for support. The project was formally submitted for consideration in July 1962. The NSF, after two years of consideration, rejected the project.

The Association, in cooperation with the Economic Research Service and the Statistical Reporting Service, financed I. T. Littleton, a graduate student in Library Science at the University of Illinois and director of the D. H. Hill Library, North Carolina State University, to do an abbreviated study. The study was begun in 1964 and completed in 1968.

I. T. Littleton presented some of his findings to the Association at the 1967 fall meetings, and his paper was published in the proceedings issue. A bulletin, *The Literature of Agricultural Economics: Its Bibliographic Organization and Use*, North Carolina State University Technical Bulletin No. 191, reporting the complete results of the study, was published in March, 1969. The statistics and ideas presented by Littleton had a major influence on events to follow. They will be considered in greater detail later.

At the 1967 fall meetings, the Association decided to enlarge the size of the committee. The aim was to provide adequate representation for the various interest groups in agricultural economics in the form of a strong, well-balanced committee, which could represent AFEA and the profession in matters relating to all aspects of the literature of agricultural economics.

The Association provided the new committee with up to $4,000 to finance a joint workshop with the National Agricultural Library to consider subject categories, the NAL vocabulary, and other aspects of library services, especially assembling, storing, and announcing the literature of the profession.

The new committee, under the chairmanship of Fred Abel, held a workshop in January 1968. Attending were the committee members, 10 people from the National Agricultural Library and guests Harry C. Trelogan and Hal King of the Inter-University Communication Council. The product of that workshop and a few followup committee meetings was the committee report represented to the Association at the fall meeting, 1968.

The Literature Retrieval Problem

Every agricultural economist knows there is a literature retrieval problem. It has been expressed many times and in many ways. Dr. Trelogan, in the background material prepared for the 1961 conference, stated it this way:

> Within the field of agricultural economics . . . it is becoming increasingly difficult for researchers, teachers, and librarians to keep up with the ever-increasing torrent of publications. This problem is particularly acute with respect to "soft cover" non-periodical materials such as bulletins, circulars, and special reports . . .
>
> The agricultural economics researcher, at many schools, is frustrated in drawing upon published results; it is becoming increasingly difficult for agricultural economics to be a cumulative body of knowledge in the research sense.

One aspect of the literature retrieval problem is that of bibliographic services, which include: (1) comprehensive and timely listings of documents in bibliographies, (2) proper cataloging (classifying) of documents, (3) proper indexing of documents, (4) systematically locating documents on library shelves, (5) quickly retrieving the documents from the libraries or obtaining copies by some other means, (6) publishing abstracts or extracts of documents, and (7) publishing summaries or state-of-the arts of research and selected areas (based on several documents).

Bibliographic Services Questionnaire

Dr. Littleton studied bibliographic services for agricultural economics literature. A questionnaire was sent to 590 agricultural economists; 379 or 64 percent were returned; many extension economists did not return the questionnaire.

Thoroughness and promptness

Respondents were asked to evaluate the *thoroughness* (comprehensiveness) with which existing bibliographic services report all important studies and the *promptness* with which completed research results are made known. Thoroughness of coverage was rated as excellent by 3.2 percent, as excellent or good by 65.4 percent, and as poor by 6.2 percent. Promptness was rated as excellent by 1.6 percent, as excellent or good by 28.7 percent, and as poor by 29 percent.

Indexing and abstracting

The respondents were also asked if the publications by the Economic Research Service were adequately indexed and reported in bibliographies. Of the 292 respondents who answered the question, 25 percent said they did not know; 37 percent and 38 percent said they were or were not, respectively, adequately indexed.

Discussion questions were asked to give the respondents a chance to suggest improvements in bibliographical organization. About 38 percent answered these questions. To the question, "Are there certain categories of publications which you have found inadequately indexed or abstracted?" agricultural experiment station bulletins were listed as being inadequately indexed by more respondents than any other type of publication. Another type of publication mentioned frequently as being difficult to find was workshop and conference proceedings, including mimeographed "working papers" and reviews of problems and research presented at industry conferences.

The questionnaire also included the question, "Do you have any suggestions as to how subject headings now being used in indexes and abstracting services might be improved?" In general, criticisms of present subject headings (descriptors, or keywords) fall into two categories:

1. There is need for greater depth of indexing, which means: (a) the use of a greater number of subject headings per item, and (b) that subject headings need to be more specific.
2. Subject headings need to be up-dated. Several respondents suggested that a thesaurus that could be constantly revised is needed because of rapidly changing terminology and the introduction of new areas of study.

Need for abstracts

Respondents were given seven forms in which research material might be presented and were asked to rank them on the basis of their usefulness. A first choice received 7 points; second choice, 6 points; and so on. The results are presented below.

Form	Score	Number of first choices
Short abstracts	1,754	123
Informational summaries of related studies	1,496	84
Complete texts	1,281	86
Critical summaries of related studies	1,251	51
Annotated Bibliography	1,069	54
Long abstracts	928	27
Un-annotated bibliography	434	7

There was general agreement that all types have their place, depending upon the purpose of the search.

Improvement of bibliographic services

The discussion question, "Do you have any suggestions for the improvement of the bibliographical control of the literature of agricultural economics?" was asked. A large number suggested some form of centralization of bibliographical reporting. About a dozen proposed the establishment of a center or central clearinghouse where important publications could be summarized and made available to a broad group of researchers and extension specialists. Some respondents suggested the need for critical review of groups of experiment station bulletins and USDA research bulletins. Several mentioned the time lag between publication and bibliographical reporting and requested greater speed in indexing and abstracting. A great many indicated that the computer should be used as an aid in speeding up and increasing the depth and comprehensiveness of indexing.

Above are the opinions of some of the members of our profession about bibliographic services. Dr. Littleton also made an objective study of bibliographic services.

Existing Bibliographic Services

Dr. Littleton's study was limited to the publications of agricultural economists in the United States, 1961 through 1963. Publications were obtained from the following sources:

1. A letter requesting a complete list of publications of staff members for 1961, 1962, and 1963 was sent to all departments of agricultural economics and some economics departments. All but two responded.
2. USDA publications were obtained from the "Checklist of Reports" issued by ERS and SRS. These lists include most of USDA agricultural economics publications. Included were all articles in *Agricultural Economics Research.*
3. Letters were sent to SRS in all state departments of agriculture requesting copies of their publications dated 1961, 1962, and 1963.

These various sources yielded 7,624 usable publications; 2,351 in 1961, 2,547 in 1962, 2,458 in 1963, and 267 with no date indicated. Of these, 51 percent were classified as research and professional, 44 percent as informational or popular, and 5 percent as miscellaneous.

Findings

Agricultural economists published 577 articles in 119 research periodicals and 1,815 articles in 347 information or trade periodicals. Agricultural economists publish in many, many different outlets. About 48 percent of publications are monographs (i.e., published as singles).

A sample of 1,527 publications was selected for checking with 8 bibliographical services to determine to what extent they were included by these services. Approximately 45 percent of publications by U.S. agricultural economists are indexed or abstracted by one or more of the eight services covered! Publications not suitable or appropriate for inclusion in any information system might be included in the original sample. However, 55 percent not indexed is very high. The indexing rates for various classes of publications are:

Class of publications	Percent indexed once or more
Total	44.54
Articles appearing in research and professional journals	80.5
Research monographs in a series	72.1
Articles in trade or informational periodicals	38.1
Informational reports or circulars	32.2
Unnumbered talks and papers	16.8
Unnumbered research reports	12.7

The indexing rates for publications from various sources are:

Source	Percent indexed once or more
U. S. government	65.3
National or regional organizations	54.1
Universities and colleges	45.9
Trade publishers and university presses	34.5

In short, indexing services miss 20 percent of the articles published in research and professional journals and 28 percent of research monographs in series (ERS reports, experiment station bulletins, etc.).

World Agricultural Economics and Rural Sociology Abstracts (WAERSA), the only bibliographical service specializing in agricultural economics, listed 8.7 percent of the publications. However, there has been substantial improvement since Littleton's study.

The *Bibliography of Agriculture* (*B of A*) *was the best service, including* 39.4 percent of the publications.

These data indicate the nature and extent of the problem of bibliographic services for agricultural economists.

An Answer

Dr. Littleton concludes, "In reviewing the special problems of selection, acquisition, and dissemination in agricultural economics, it seems clear that a specialized information center, working in cooperation with the National Agricultural Library, would be highly desirable to achieve control of the literature."

Thus the Association moved, early in 1969, to establish the Center. As originally planned, the Center would be run cooperatively by AAEA, NAL, ERS, and SRS.

As efforts were made to establish the Center, it became clear that it would be easier to administer if some of the functions were separated. Accordingly, the Center is funded by NAL, ERS, and SRS. Determination of what the Center will do and publication was left to the Association. Henceforth, the term "Center" will refer to the Center as it is being established by NAL-ERS-SRS.

The Center

The Center will be staffed with two full-time agricultural economists. The economists will be looking to the Association and users of the Center for guidelines on what to include in *ABAE* and how to index the items.

The objectives of the Center are:

(a) to acquire agricultural economics literature written by U.S and Canadian agricultural economists and other important related literature;

(b) to prepare the bibliographic data, copy abstract (if contained in original document), and index (assign keywords) for acquired documents;

(c) to have the prepared information transfered to computer tape;

(d) to make computer tape available to AAEA and other interested parties every two months;

(e) to maintain a master type with accumulated data from the bi-monthly tapes; and

(f) to perform computer searches on request and at cost.

The Center will have to establish its own system for acquiring and screening documents. The NAL will acquire the periodicals the Center needs. However, the Center does not want to review or scan periodicals that carry only one relevant article in three years (200 such publications revealed in Littleton's study).

If the Center is to obtain copies of articles published in remote journals or periodicals or papers presented at workshop or symposium, the author will have to send a copy of his publication to the Center. The Center can accomplish comprehensive coverage of the agricultural economics literature only if each agricultural economist assumes responsibility for sending copies or knowing that copies of his publications have been sent to the Center.

The Center will conduct computer searches of the master tape on request for cost. The cost will vary according to number of keywords used in the search and the number of documents on the tape. Cost for searches in the Pesticide Information Center have run between $35 and $180. The Center will not be in a position to make computer searches for a year or so. It is unlikely that a search of the collecton would be worthwhile before then anyway, since so few documents will be on the tape.

The Association is working to complete an agreement with NAL-ERS-SRS. The agreement will establish the formal relationship that will exist between AAEA and the Center.

There is no reason to go into detailed costs of the Center at this time, since AAEA will not be paying any of them. The annual cost of the Center will be about $50,000.00.

The Association's Role

Because the Center is going to be run, at least financially, independent of the Association, the Association's primary role is in publishing the bibliography. When completely operational, the Center will supply the Association with computer tape every two months containing the bibliographic data, abstracts, and keywords. It will be the Association's job to have the information on the tape transfered to a photo copy and to publish the bibliography. The Association may also find it necessary to publish an annual index of all the things contained in the monthly bibliographies.

The cost of the Association should be in the neighborhood of $15,000 per year. Thus, the members of the Association will be getting the product of a $65,000 a year literature retrieval service for about $15,000.

The American Bibliography of Agricultural Economics is scheduled to be published every two months. It should contain between 600 and 700 items. An item here means all the bibliographic information from a single document plus an abstract if contained in the original document. Each issue will contain a subject index. In the subject index, each of the keywords used to index at least one document will be printed. Behind the keyword will be the item number corresponding to the document to which that keyword was assigned. There will also be an author index and a corporate author index.

The Association agreed at the Chicago meeting last December that the first few issues of the bibliography would be sent to all members of the Association. After that, they would be given a chance to subscribe. The subscription to the bibliography would be independent of the subscription of the JOURNAL. I feel very strongly that to do it this way would be a mistake. All members of the Association will benefit from the services of the literature retrieval center. I see no reason why a few voluntary subscribers should subsidize the other members of the profession. There is evidence that voluntary subscriptions to a bibliographic service will not support the service; for example, the *World Agricultural Economics and Rural Sociological Abstracts* had a very low subscription rate with the idea that a large number of people would subscribe and pay for the system. However, voluntary subscriptions were very low. In order to solve the problem they raised their subscriptions rates to where it is now almost impossible for an individual to subscribe. Another example a little closer to home is the experience of the American Economic Association. When they started producing the *Journal of Economic Abstracts*, subscription to the abstract journal was voluntary. The option of subscribing was included on the membership dues form. Not enough members voluntarily subscribed, however, to cover the costs of the system. Their solution was to raise the dues of the Association $3.00 to cover the cost of the *Journal of Economic Abstracts*. Now every member of the Association receives the abstract journal along with the *American Economic Review*. This is the way I think our bibliography ought to be handled. Special arrangements would of course have to be made for our Canadian members so that they would not subscribe twice.

It was also decided at the Chicago meeting that subscriptions to the bibliography from libraries would be charged at a substantially higher rate than the charge to members. The exact charge has not yet been determined.

Literature Services—The Big Picture

Agricultural economists have known for a long time that there is a literature retrieval problem. We can all think of many cases where important research was done and we did not discover it until much, much later. We are also aware of how difficult it is to go back and make a comprehensive search of what kind of research has been done on any particular topic. The Agricultural Economics Documentation Center and the *American Bibliography of Agricultural Economics* are the first and very large steps for solving this problem. However, by themselves they will not meet all of our literature retrieval needs. There would be many other parts to a really comprehensive literature retrieval system.

The problems of dissemination and retrieval of knowledge of and about publications can be divided into three more specific problems:

1. becoming aware of documents recently published (by some form of announcement publication or citation index);
2. finding out something about the document (by some form of abstract and/or form of subject classification); and
3. locating historical publications (i.e., some form of literature retrieval system).

These problem areas are not independent, and partial solution to all of them will be contained in a single comprehensive system.

The first problem, becoming aware of documents, will be solved to a substantial extent by the *American Bibliography of Agricultural Economics*. There is another system—the citation index system—by which agricultural economists can become aware of documents.

In searching for documents relevant to a selected subject, it is often most productive to start with a recent publication written in the subject area to see what documents are cited. The search can be continued by locating the cited documents to see what documents they cited, and so on. A citation index is designed to facilitate this kind of search. If the index presents documents cited as well as documents doing the citing, it is possible to search forward. If, for example, a person were interested in inter-regional competition and knew of Heady's bulletin, they could search to determine whether anyone had written a document that cited Heady's bulletin.

A citation index can be developed independent of all other bibliographies services except acquisition. It is simple to prepare because there is no need for classifying, indexing, or abstracting, etc. Input for the index is simply copying, with no professional involvement except supervision. The ease of use and efficiency is primarily a function of how good a job of citing the author does.

There are many ways of finding out something about the document. They include a verbal report from colleagues, subject classification, index terms, abstract, reviews, and scanning the document. The bibliography will convey information about the documents by index terms and an abstract, if the abstract was included in the original document. There are no plans to provide additional information about the document at this time. A more comprehensive literature system might very well provide additional information, particularly in the form of reviews.

There are two parts to the third problem of locating historical publications. One part is obtaining the title and author of the publication, and the second part deals with getting a copy of the publication. The current system composed of the Center and the bibliography will help in locating historical documents from the time the Center is established forward. One can locate the documents by using the bibliography or later, when a larger collection is on the tape, by computer searches. If the citation index described above were established, it would also be a means of locating documents. Documents prior to the establishment of the Center would have to be located in traditional ways.

The Center and the bibliography will not help at all with the second problem —obtaining the publication. Agricultural economists will obtain the titles from the bibliography or the computer search and then use the usual means of obtaining hard copies. It is not planned that the Center would ever disseminate original or hard copies of the document. However, a comprehensive system might very well distribute microfiche of the document.

Since a microfiche system might effect all three of the problems concerned with literature retrieval, I will describe it in more detail. The microfiche is a four-by-six-inch transparency which will hold a micro-copy of sixty to seventy pages. If the publication is less than sixty pages long, it will be on one microfiche; if more than sixty pages, it would be on two or more microfiche. Only one publication would appear on any one microfiche. An eye readable title and accession number are printed on the top of the microfiche.

If desired, the Center could have a microfiche master made of all documents received in the Center. This would cost about $4.00 per fiche. If members wanted a copy of a document they would only have to send an order to the Center. The Center could copy the master microfiche and send the copies to the requester. The cost of copying a microfiche would be about 20 cents, which should be charged to the requester.

The microfiche could then be read on a special machine, now costing a little over a $100.00. There are machines, somewhat more expensive, that can reproduce from the microfiche a hard copy of any page. The hard copies would be very much like xerox copies.

There are many advantages to a microfiche system. People could keep the microfiche copies as long as they wanted. There would be no need to return them to the Center or to a library as in the traditional lending procedure. Microfiche dissemination would be an excellent way to distribute widely documents now printed for only limited distribution. To maintain a file of microfiche is much more convenient than a bookcase.

In a slightly more advanced system, the Center could maintain a file of the subject matter interest of all the members of the profession. The file would record the keywords or descriptors describing the area of interest of the members. As documents came into the Center, they would be microfiched. If the descriptors assigned to the document matched the descriptors listed by any of the members, a microfiche copy would be sent to them. The member could scan the microfiche and throw it away or store it according to whether it met his needs or not. A selective dissemination system like this would be quite expensive.

Those are the highlights of what could be an expanded literature retrieval system. All of these concepts were discussed by the literature retrieval committee at their January 1968 meeting. However, the committee did not make any recommendations concerning these expanded services. It was believed that the important task was to get the Center established and to get the bibliography published and disseminated. Now that this is being accomplished, it may be appropriate for the committee to go back and review these other services and make recommendations to the profession.

FRED H. ABEL, *Chairman*

Address of the AAEDC

After January 1, 1970, agricultural economists should send copies of their documents to:

American Agricultural Economics Documentation Center
National Agricultural Library
Care of S.B.M.U.
U.S. Department of Agriculture
Washington, D.C. 20250

REPORT OF THE PROFESSIONAL ACTIVITIES COMMITTEE

The officers of the American Agricultural Economics Association established the Professional Activities Committee in 1968 to assist in the achievement of its main objective: to further the development of systematic knowledge of agricultural economics. The Association continues to pursue this objective by facilitating scientific research, instruction, publications, meetings, and other activities designed to advance and disseminate knowledge in agricultural economics.

In addition to recognizing the objective of the Association and its activities, the committee further recognizes that its members are not universally and equally served by existing activities. Identifiable subgroups have specialized subject matter and area interests. The changing nature of our society, indeed, our total environment, forces review and reassessment of activities. Advancements in knowledge in related social and agricultural sciences particularly affect the posture of agricultural economics.

With these facts as given, the committee pledges that new or expanded activites will be proposed only if they further facilitate the achievement of the objective of the Association and at the same time encourage greater unity, cohesiveness, and relevance for those who pursue agricultural economics as a profession. It is in this spirit that the following list of activities was selected to receive early and serious attention by the committee.

1. *National Academy of Science.* It is the recommendation of the professional Activities Committee that the Association adopt a position of interest in involvement with the Division of Behavioral Sciences. Perhaps the best strategy to implement this interest would be moves to obtain the appointment of an agricultural economist to the members-at-large category of the division. Once this action is accomplished, the AAEA could be presented for recognition by the division.

To implement this recommendation, the board of the Association should prepare a list of two or three people whom they would support for appointment as members-at-large.

2. *Promotion of exchange of staff members between university, government, and industry.* The committee recognized this as a desirable area for development.

a. Exchange between university and government—Dr. Upchurch of ERS and Dr. Breimyer, president of the Association, have initiated communication efforts in ERS and the Association. Dr. Ray Scott, FES, also has written Dr. Breimyer concerning exchange between universities and FES. The committee encourages continued efforts to communicate opportunities.

b. Ron Aines as chairman of the Industry Committee has explored with the committee and members of the Professional Activities Committee ideas and opportunities for exchange between universities, government, and industry. A report at this meeting will be made by the Industry Committee.

3. *Accreditation or certification.* The committee discussed the opportunities and problems involved in accreditation of the departments of agricultural economics and certification of individuals as agricultural economists.

The committee quickly reached the conclusion that in their judgment the Association should not undertake such activities.

4. *AAEA Visiting Lecturer Program.* The committee recommends the establishment of a visiting lecturer program. The program would be somewhat similar to the AEA visiting scientist program. It is proposed that the universities eligible for the visiting lecturers would be those offering an undergraduate or master's degree in agricultural economics but not a Ph.D. degree.

The initiation of such a program would make available to Negro land-grant colleges, a number of non-land-grant colleges, and a few land-grant colleges that do not offer a Ph.D. the opportunity to schedule a lecture by a distinguished agricultural economist. By paying the travel expenses only of agricultural economists and by careful scheduling, $2,000 or $3,000 per year should make available professional stimulation to many students and faculty of non-Ph.D. schools.

The committee recommends the appointment of an AAEA Visiting Lecturer Program Planning Committee to develop plans and to obtain new funds. It would be the responsibility of this committee to develop procedures for selection and scheduling of the visiting lecturers as well as raising funds.

5. *Career planning information for undergraduate recruitment.* In June 1969, a questionnaire was distributed to 54 heads of departments of agricultural economics in the United States. It concerned the need for preparing a brochure describing professional careers based on academic training in agricultural economics. A majority of the departments of agricultural economics in the United States expressed definite interest in some kind of brochure on professional careers based on academic training in agricultural economics. More than half wanted some kind of national effort to at least consider this possibility more thoroughly. A few opposed "wasting Association and professional time" on this kind of project. Some registered reservations on the returns to such an effort. A few were also very optimistic citing what they termed a successful effort by the discipline of animal science on this kind of venture.

On the basis of the comments received and the evidence obtained in the questionnaire, we recommend that the president of the Association appoint a small committee of members to work with a professional writer in preparing copy for a potential national brochure. The committee should then recommend whether the copy should be released as a national brochure or as materials to be used by individual colleges in producing their own brochures. The committee might well be charged with preparing basic copy in the next six months and distributing a first draft to all departments for comment and reaction. The Association would be asked to underwrite costs of such an initial effort. The new committee on the basis of its work and experience should then recommend what subsequent action should be taken.

6. *Future Activities.* The committee plans at future meetings to investigate the following areas:

a. Dissemination of information on stipends for graduate students.
b. Development of curriculum for extension and resident instruction.
c. Need for exchange of information concerning AID research and educational activities.
d. New publication outlets for teaching, research, and extension.
e. Association sponsored review and evaluation panels, voluntarily requested by departments.
f. Association sponsored research and policy commissions.

Respectfully submitted,
R. J. Hildreth, *Chairman*

REPORT OF THE CONTRIBUTED PAPERS COMMITTEE

Contributed papers were assigned a more significant role in this year's annual meeting. At least three innovations are worthy of mention: (1) the overall program was modified to incorporate a larger number of contributed papers than previously, (2) some contributed papers were assigned to invited papers sections where topics were such to make it desirable, and (3) special contributed papers were invited to respond to a base paper published by Dr. James Shaffer in the May issue of the Journal. It is useful to classify the papers into two categories: (1) regular contributed papers and (2) special contributed papers. The latter refers to those responding to the Shaffer paper.

Papers were grouped according to the following title headings:

Session title	Received	Selected
	Number	
Regular		
1. Tools of our Trade	8	3
2. Empirical: Price Analysis, Marketing	21	6
3. Production Economics and Farm Management	16	5
4. Rural Development and Demography	18	4
5. Tools: Teaching, Research and Curriculum	9	4
6. Tools and Empirical: Natural Resources, Foreign Trade, Foreign Economic Development	13	4
7. (For invited sessions)	3	2
8. (Rejected because of length)	3	-
Total regular papers	91	28
Special		
1. Responding to Shaffer paper	14	3
Total contributed papers	105	31

In total, 105 papers were received (of which 102 were accepted) and 31 were selected by the committee. That gave a selection ratio of 30 percent. Since there will be about 60 presentations at the annual meeting, it means about one-half of all presentations will be contributed papers. More contributed paper sessions were arranged this year by the Planning Committee. At the same time session topics were more limited in scope than formerly.

The effects of this year's innovations cannot be evaluated fully at this time. It will be essential to get responses from those attending the meeting to have a complete evaluation.

In general, we were pleased with the quality of papers received. In some instances quality was lacking. But in those cases the number received was such that quality selections were possible. Some problems existed in classifying papers into groups. One was due to a misleading abstract but others were due to an attempt to fit papers received into topic areas that had been at least in part predetermined.

The innovation of special contributed papers in response to the Shaffer paper would appear to be a desirable one. But for one committee to handle these as well as the regular ones was confusing. Apparently it was confusing to those reading announcements calling for contributed papers. Also, extra problems were created in the mechanics for handling them. Perhaps a separate mechanism should be established to handle any special contributed papers in the future. Otherwise, we would recommend that the contributed papers activity be continued much as it was handled this year. It was gratifying to have such a splendid response from those submitting papers. Also, it is commendable that the Executive Committee would modify the annual meeting program to include such a large number of contributed papers.

MILTON L. MANUEL, *General Chairman*

REPORT OF COMMITTEE ON EVALUATION OF AAEA EMPLOYMENT SERVICES

President Harold Breimyer of the AAEA appointed a committee composed of R. J. McConnen of Montana State University, James Nielson of Washington State University and Max Thorp of the USDA both to evaluate and to investigate possibilities for improving the employment services provided by the AAEA during its annual summer meeting.

Potential employers and potential employees who used the employment services in 1968 were mailed the appropriate attached questionnaires in order to obtain information which would help the committee accomplish its objectives. All agricultural economics departments in land-grant schools and one-fourth of the remaining potential employers who used the AAEA employment service in the summer of 1968 were sampled. Of the 75 potential employers sampled, 58 responded. One-fourth, or 55, of the potential employees who used the AAEA employment service in the summer of 1968 at Montana State University were sampled. Of these, 34 responded. The results presented below refer to respondents only and not to the total number of potential employers and employees.

Results of Potential Employer Survey

As a result of using the services of the Employment Committee, five employers hired or completed negotiations for hiring professional personnel during the meeting. These positions were for four assistant professors, one GS-9 and one

GS-11. In all of these successful agreements, the employee made use of the employment service. Communications between the prospective employee and employer prior to the meeting were reported in three cases.

Twenty employers hired or completed negotiations for hiring 25 professional people because they became aware of the applicants during the meeting. These positions filled were 19 assistant professorships, two research fellowships, two as agricultural economists, and one each as instructor and civil service GS-12. The employee used the employment service provided by the AAEA in 23 of the successful agreements. Two employees who were hired made no use of the service. Communications prior to the meeting between the prospective employee and employer were reported in nine instances. Ten of the employees using the employment service had no prior communications with their prospective employers.

Negotiations initiated as a result of contacts made with the assistance of the employment services activities are still being pursued in ten cases. Forty employers reported that they are no longer negotiating because of contacts made at the meeting. This could mean that the positions are filled or that there were never any contacts made at the meeting.

Thirty-seven employers gained some information about the general supply of agricultural economists. Specifically, 19 responded that they gained reliable knowledge about the salary level of agricultural economists, 18 gained knowledge about the quality and training of the applicants and 4 learned about the interests of the applicants. Twelve respondents gained no or only limited information about the market for agricultural economists.

Of the employers who were recruiting, 39 responded that they had hired professional people without the use of the services provided by the Employment Committee at Montana State University (some employers were recruiting for more than one position). Personal contacts were credited as the basis for filling 32 positions. Four employers used other professional employment services.

Fifty of the respondents thought that it would be helpful to them if the Association would provide "market" information—especially salary information—about agricultural economists. Forty-nine would be willing to provide the necessary basic information if the Association were to provide information on starting salaries for agricultural economists of the type published in the table attached to the employer questionnaire.

Twenty-two commented that they would like to see the AAEA continue the service with some minor changes. Ten would like to see some major changes in the structure of the employment service. Many employers would like a brief digest of potential employees some time in advance of the meetings so as to screen the applicants before the time of appointment. "The present situation allows 20 people to bore a man and not give him an easy way to say—your credentials are not appropriate." It was also suggested that because of the openness of the applications some people will not file because they do not want to run the risk of formally entering the job market.

One person found the card and board method for arranging meeting times and places between employer and employee a game of blind man's bluff. Some complained of the crowded conditions of the meeting rooms.

One respondent went so far as to suggest that the AAEA have a national office and full-time staff so it could render a clearing house service for both those interested in employment and those seeking employees.

Some felt that the hurried pace of the "Employment Merry-Go-Round" took something away from the AAEA meetings and suggested that the service be held following the meetings, but not in competition with the program.

In general, however, potential employers found the employment service useful, particularly as a means of obtaining information about salaries, training, and other general market information. The present procedure means that using the employment service requires considerable time.

Results of Potential Employee Survey

As a result of using the services of the Employment Committee, three of the potential employees accepted or completed negotiations for accepting a professional position. These positions were as an accounting executive of the New York Stock Exchange and two assistant professors. In two of these three successful agreements, the employer made use of the employment service. Communications prior to the AAEA meeting between the prospective employee and employer were reported in one case. Thirty-one of the respondents did not accept or complete negotiations for a professional position at the AAEA meeting in Bozeman, Montana.

Eight potential employees accepted or completed negotiations for accepting professional employment because they became aware of these positions during the meeting. All eight of these positions were as assistant professors. The employer used the employment services in six of these cases. Communications prior to the meeting between the prospective employee and employer was reported in one case.

Negotiations initiated as a result of contacts made with the assistance of the Employment Committee's activities are still being pursued in two cases. Thirty-one reported that they are no longer negotiating because of the contacts made at the meeting.

Sixteen gained some information about the general demand for agricultural economists, nine found out more about the salary level of agricultural economists, eight gained knowledge about positions available in the field, and two learned about the qualifications about the general market conditions for agricultural economists.

Of the respondents who had not accepted a position because of negotiations held at the meeting in Bozeman, Montana, or because of negotiations completed after the meeting but which were initiated by the Employment Service, 13 have accepted positions which did not require any of the services provided by the Employment Committee. Personal contacts were credited for getting a position in seven cases. Three credited former faculty members with initiating the contacts, and three used other professional employment services.

Twenty-two prospective employees thought that the service should be continued or expanded. Four would like to see some major changes to make the service more efficient. Some thought that the service is primarily aimed at Ph.D. level for faculty positions. While the USDA and the universities were well represented several indicated that they would like to see a greater participation by industry.

A better organization for getting better information about job openings and prospective employees on file earlier was suggested.

One respondent suggested a year-round service which would be on a subscription basis to be paid for by the prospective employee and employer. This would include a monthly bulletin, a separate one for employers and employees, listing individuals available for employment with a brief vita and a listing of available openings with a description of the employing institution.

One person would like to see the service discontinued completely since the top jobs generally do not come through the service anyway. He thought that anyone strong enough to complete a Ph.D. should have enough "get-up-and-go" to find his own job.

The comments made by potential employees, indicated specific ways in which they thought improvements could be made. Only a few suggested the service could be eliminated. Suggested improvements indicated the desire for more copying equipment, better messenger service, greater privacy for interview areas, etc. It was also suggested that more information on jobs be made available before the meeting. To implement these suggestions would require considerable additional expense.

Recommendations

Based on survey results, there seems to be no basis for recommending that the Association stop sponsoring employment services at their annual summer meetings. While not a great many people were hired and not a great many positions were filled, the employment service does provide a means by which both potential employees and potential employers gather considerable market information.

The operation of the service could be improved, but the specific improvements would require more detailed study than was possible by this committee. One common complaint was the large amount of interview time required to utilize the service as it is presently operated. Suggested changes included restricting the availability of employment services to a period of time either before or after the main meetings and publication of information on employees and positions prior to the meeting. However, there appears to be no single improvement that could be made without considerable cost either in dollars or additional space for the employment service.

Employers indicated that the kind of salary information supplied by the table attached to the employer questionnaire would be very useful, and they would supply the needed basic information. Therefore we recommend that the Association investigate the possibility of publishing information on both the level and dispersion of starting salaries on an annual basis.

R. J. MCCONNEN, *Chairman*

REPORT OF THE NATIONAL BUREAU OF ECONOMIC RESEARCH DIRECTOR

This comment on recent activities of the National Bureau of Economic Research can cover only a few of the highlights that may be of interest to agricultural economists. Those who wish more complete information are referred to the Forty-eighth Annual Report, June 1968, and the Forty-ninth Annual Report, October 1969. There has been considerable emphasis on review of research programs. Some organization changes have been made in the Bureau to provide more flexible and efficient framework for developing new research activities.

Research Emphasis

The Bureau program, built on basic quantitative research on economic problems that are relevant and are expected to be important to our society in the years ahead, is shifting toward social measurement and economics of growth.

The major sections of research listed in the staff progress reports for the spring, 1969, are: (1) economic growth; (2) national income, consumption, and capital formation; (3) urban economic studies; (4) human resources and social institutions; (5) regional studies; (6) business cycles; (7) financial institutions and processes; (8) studies in industrial organization; (9) international studies; (10) econometric methodology; (11) research information processing; and (12) conference programs, including the Conference on Research on Income and Wealth and the Universities-National Bureau Committee for Economic Research. It is hoped that a new third conference series can be developed as an "Interinstitutional Conference on the Application of the Computer to Econometric Research." This conference would be somewhat along the lines of the Conference on Income and Wealth, with roughly 50 to 100 people from various universities, government organizations, and others from non-profit organizations meeting periodically to exchange information and otherwise to keep one another apprised of developments in the computer field. The conference is intended to reduce overlapping and duplication in computer analysis programs of various institutions and to serve as a forum for discussion of new ideas and techniques. Agricultural economists, who have pioneered much of the work in this area, should be interested in this development.

The Bureau will give considerably more attention to problems of social measurement and to the processes of economic growth if suggestions of many people familiar with work of the Bureau are followed. The most frequent response to a question from the president of the NBER about what the Bureau should emphasize in the 1970's was, "The Bureau in the 1970's should do for social statistics what it did for economic statistics in the 1930's."[1] A second rather common reply was that the Bureau should devote more attention to the processes of economic growth. Some urged that the Bureau concentrate exclusively on such studies.

These suggestions, if followed, will not be contrary to the long tradition of the Bureau, but they will involve an important shift in emphasis. Studies of the processes and consequences of economic growth or development will require that more attention be given to intersector relationships in the economy, to questions concerning improvement of environment, and to important areas of inquiry going beyond traditional market concepts. One of the most important basic assumptions underlying priorities in the work of many economists, perhaps including many at the National Bureau, almost since its founding in 1920, has been the idea that, if we could eliminate serious business recessions and keep the aggregative rate of growth in the economy to some respectable level such as 3½ percent to 4 percent a year, most other economic and social problems would tend to solve themselves. Increasingly, this assumption is being called into question. It is quite clear that we have achieved a high rate of growth for many years now, and economic recessions have been relatively minor. Surely the research in which the Bureau has been involved has contributed importantly to these two results, but large and significant economic problems exist that apparently will not be solved simply by maintaining stability and a high rate of growth in national product. Currently problems that plague society most, which have both social and economic implications, are mainly offshoots, by-products, or external diseconomies of the market-oriented system.

---

[1] See John R. Meyer, "National Bureau: Continuity, Change and Some Future Perspectives," in *Toward Improved Social and Economic Measurement*, Forty-eighth Annual Report of the National Bureau of Economic Research, Inc., New York, June 1968, pp. 1–10.

Urgent demands for social and economic research that have been suggested or identified have to do with the environmental conditions and include items such as inadequate housing for particular segments of the population, inadequate recreational facilities, congestion in transportation, developing slums, air and water pollution, uneven or unequal employment opportunities, and an undesirable lack of aesthetics in the modern environment. A significant problem is the inadequate working of the factor market, particularly as it applies to labor, resulting in inequities and social unrest. The implication is that a private research organization such as the National Bureau should place more emphasis on research having to do with social measurement, with problems of welfare or equity, and with research pointing the way to improvement in society's organization and environment. Research on business cycles and on questions of stability apparently has progressed—importantly as a result of National Bureau leadership—to the point where more urgent research priorities exist.

Analytical Approaches and Disciplines

A more comprehensive analytical approach will be required if the problems mentioned are to be researched adequately. The new approach bears a relationship to "systems analysis." It will require both micro- and macro-analytic models of growth. An appropriate research design will need to accommodate the interdependencies, non-linearities, and other complications in processes by which groups and institutions adjust to economic change. The essence of such research is developing a better sense of how different parts of the economy relate to one another.

The trend toward social measurement in Bureau research will involve some projects chosen at the interface between economics and other social sciences. The Bureau staff, which has been made up almost entirely of economists, may need to include other social scientists, such as sociologists and psychologists, who have much to teach economists about basic sources, survey techniques, field work, and strategies for improving data in the area of social measurement.

Although the major emphasis of the suggested research relates primarily to the urban economy and its complications, there also is much in this that should be of interest to agricultural economists. We are concerned first with a segment of society that has seen its welfare problems accentuated and some of them exported to the urban sector while, at the same time, the markets for most factors used in agriculture have improved in quality and efficiency. We are concerned not only with how resources are organized and allocated in agriculture and the rural community, but with how the adjustments between urban and rural community can proceed with more efficiency, greater equity, and more recognition of the dignity of people. The growth and adjustment process requires more help for people in fitting into the modern economy. We are or should be greatly concerned with reducing imperfections in the intersector resource market, particularly as it applies to people. Some of the most acute urban problems—congestion, decay, poverty, and racism—have an important part of their roots in the inadequacies of education and social services in the rural society, in the lack of job training offered to migrants from rural areas, and in the failure of the business community to maintain a satisfactory rate of growth and improvement in rural sectors. Such problems need further research, and the question of how agricultural economists can contribute or correlate important parts of their work with the National Bureau is of increasing importance to us.

In Summary

Efforts to move toward social measurement and economics of growth or toward using the tools of economic analysis to aid in achieving social objectives are regarded as a shift in emphasis rather than as a break with the tradition of the past 50 years. Much will go on as before; but some of the new orientation is already evident in the Bureau research on education and medical economics. The goal is to move into other problem areas where environmental improvement is most urgent. In this research, as well as in the more traditional areas, more emphasis is being placed on development and use of modern tools of econometrics, mathematical theory, and the electronic computer. Both in new and in more traditional areas the Bureau hopes to play a greater role in organizing research resources, in complementing programs of research in universities, government, business, and other foundations, and in stimulating new ideas and hypotheses for research. Agricultural economists will benefit by greater awareness of these trends, and the Bureau program may be strengthened by their greater involvement.

HAROLD G. HALCROW, *Director, National Bureau of Economic Research,* representing the American Agricultural Economics Association

MINUTES OF THE EXECUTIVE BOARD MEETING

Chicago, Illinois, December 27–28, 1968

Meeting called to order at 3:00 P.M., December 27, 1968.

Present:

Members: Breimyer, Hathaway, Dunbar, Hillman, Butz, Wharton

Ex officio: Kearl, Swanson, Rudd, Nielson

Guests: Ackerman, Jones, Redman, Hamilton, Hildreth, Upchurch

1. Dunbar moved approval of the minutes of the meeting of the Initial Governing Board and the Executive Board held at Bozeman, Montana, August 1968. Seconded. Passed.
2. Breimyer discussed the organizational committee structure and the assignments of Board members of the Association.
3. Hamilton reported on local arrangements for the Chicago winter meetings.
4. Jones reported for McConnen on the finances of the annual meetings held at Montana State University. The deficit, according to Jones, is $3,188.90. Written reports have been mailed but have not arrived. The subject of the deficit was discussed, and the matter was postponed pending receipt of the reports.
5. Redman presented a budget and reported on preparations for the annual meetings to be held in Kentucky in August 1969. Hillman moved that the Kentucky meetings budget be revised and $200 allocated for women's activities with $100 for coffee and $100 to be used as needed. Seconded. Passed. Hillman moved that up to $200 be provided for young people's entertainment on Tuesday evening. Seconded. Passed. Other changes to be made reduced the budget to $9,950. Dunbar moved that the registration fees be:

Regular members	$ 8.00	Individual
	11.00	Family
Graduate students	6.00	Individual
	9.00	Family
Non-members	12.00	Individual
	15.00	Family

Seconded. Passed.

Meeting recessed at 5:30 P.M.

Meeting reconvened at 7:30 P.M.

Present:

Members: Breimyer, Hathaway, Dunbar, Hillman, Butz, Wharton

Ex officio: Kearl, Swanson, Rudd, Nielson

Guests: Ackerman, Jones, Redman, Hamilton, Hildreth, Upchurch

6. Swanson reported that he is completing the work on the Proceedings issue of the *AJAE* and that the arrangements have been completed for Fuller to take over the editorship.
7. Ackerman reported that the joint ASA-AAEA Advisory Committee on Agricultural Statistics had not met but that it had formalized its organization with rotating membership made up of three members from each association and an elected chairman. The committee was requested to have as one of its charges the review of the adequacy of available statistical information and the consideration of studies that need to be made. Dunbar moved that the committee be encouraged to develop proposals for an evaluation and appraisal of agricultural statistics, that members be added to the committee as needed and that the payment of expenses as necessary for up to two meetings for the joint ASA-AAEA Committee be made by the Association. Seconded. Passed.
8. Ackerman raised the question of the Association's financing a meeting of the Fellows Election Committee. No action was taken.
9. Ackerman reported activities in advising on the U. S. Census.
10. Hildreth reported that the Professional Activities Committee had met and had considered the philosophy and policies to be guide lines for the work of the committee. The committee is to meet in March and will prepare proposals to bring to the Executive Board at its August meetings.
11. Kearl reported on the membership of the Association and indicated that it has not increased during the year as it should have done. Wharton pointed out the possibilities of lowering the cost of foreign subscriptions as a means of increasing the service of the Association to foreign agricultural economists living in areas where there are exchange problems.
12. Breimyer presented a proposal by the Student Affairs Committee to raise funds for the student association through the sale of membership certificates. It was pointed out that the student organization has no status as far as the present Constitution and Bylaws of the Association are concerned. Breimyer is to contact Neil Harl with regard to drafting rules for organization of the Student Agricultural Economics Association Clubs and their relation to the AAEA.

13. Breimyer discussed the Association's relation to CEANAR and the National Academy of Science. Upchurch is to obtain information about the Academy for distribution to the Board members. The Association's relationship with CEANAR and the National Academy is to be considered by the Professional Activities Committee.
14. Breimyer discussed the question which has been raised as to the effectiveness of the employment center at the annual meetings. Nielson, McConnen and Tharp are to be asked to serve as an ad hoc committee to study the matter.
15. The matter of the preparation of a brochure on career opportunities in agricultural economics was considered. No action was taken on the specific proposal. The matter of recruiting students will be considered as a part of the work of the Professional Activities Committee.
16. Breimyer indicated that he will attempt to improve communications with members of the Association via letters to the members and may initiate a special mailing for this purpose.
17. Wharton moved that Rhodes, Chairman of the Department of Agricultural Economics at the University of Missouri be authorized to contract with the appropriate officials at that university for housing and dining facilities in connection with the 1970 annual meetings. Seconded. Passed.
18. Breimyer expressed his opinion that businesses and others who wish to support the activities of the Association should be supporters of the Association through its Sustaining Membership program which has the particular function of financing the Awards Program. Wharton moved that the Board support the position of the President. Seconded. Passed.
19. Hathaway moved that the Board meet on the Saturday and Sunday prior to the Kentucky annual meetings. Seconded. Passed.
20. Breimyer reported the progress in developing the annual meetings program.

Meeting recessed at 10:30 P.M.

Meeting reconvened at 10:30 A.M., December 28, 1968.

Present:

Members: Breimyer, Bishop, Toussaint, Butz, Dunbar, Hillman, Hathaway, Southern

Ex officio: Rudd, Nielson, Kearl

Guests: Fuller, Redman, Martin, Upchurch, Hildreth

21. Further discussion of the budget for the Kentucky annual meetings involved an increase in the administrative allowance for secretarial help to $2,400 and adjustments in the reserve funds to balance the budget. Hathaway moved that the budgeted expenses and receipts for the Kentucky meetings be approved as amended and that the registration rate be set as previously approved. Seconded. Passed.
22. Martin reported the activities of the Committee on Postwar Work in Agricultural Economics. The committee proposes that a series of review articles be prepared and published over the next five years and that, although financing should be obtained elsewhere, the Association should underwrite the project to enable the committee to move ahead. Southern moved that the report be accepted, the committee be discharged, and a steering committee for the project be appointed. Seconded. Passed. Hillman moved the ap-

pointment of a steering committee, composed substantially of the same individuals as the review committee, to firm up the outline for the review series and prepare a budget. The committee is to be authorized to commission articles without honoraria. Expenses for committee meetings are authorized. Seconded. Passed.

Meeting recessed at 11:45 A.M.

Meeting reconvened at 12:50 P.M.

Present:

Members: Breimyer, Hathaway, Butz, Toussaint, Dunbar, Southern, Bishop, Hillman

Ex officio: Nielson, Rudd, Kearl

Guests: Fuller, Redman, Hildreth, Ackerman, Upchurch

23. Fuller reported the progress in taking over the editorship of the *AJAE*.
24. Nielson presented a report for the Awards Committee. It was suggested that a review be made of the awards program and the criteria for making selections of award winners. In lieu of a review the Awards Committee is encouraged to revise, as needed, the rating sheets and other methods of determining award winners.
25. Southern discussed the activities of the Committee on the Retrieval of Agricultural Economics Literature and explained the project for establishing a Documentation Center. Hillman moved that the Association approve the project and that a Directing Committee be appointed, including a Canadian member. The committee is to be authorized to move ahead with the development of the Documentation Center. It is to develop plans for a cooperative agreement with the National Agricultural Library and the Economic Research Service for the operation and financing of the Center including the solicitation of outside funds as may be needed. It is suggested that consideration be given to financing the Center through subscription rates for the service. These subscription rates would be varied, depending upon whether the subscriber was a library, department, or individual. The Association is to underwrite the cost of the service to the extent of a total of $50,000 over a period of three years. Initially, all members of the Association and subscribers to the *AJAE* are to receive listings from the Center with the announcement that such service would be given on a continuing basis for a subscription payment over and above the regular *AJAE* subscription. Seconded. Passed.
26. Southern moved that the Board should encourage the expansion of the Association's student activities to schools of all sizes and kinds, including Canadian and non-land-grant institutions. Seconded. Passed.
27. The financial problems in connection with the Montana meetings were briefly reconsidered and the President and Secretary-Treasurer were instructed to obtain more information as to the nature of the deficit.

Meeting adjourned at 2:15 P.M.

MINUTES OF THE EXECUTIVE BOARD MEETING

Lexington, Kentucky, August 16–17, 1969

The meeting was called to order by President Breimyer at 9:05 A.M. August 16, 1969.

Present:

Voting members: Breimyer, Hathaway, Dunbar, Butz, Toussaint, Wharton, Hillman, Bishop (Absent Southern).

Ex officio: Kearl, Purnell, Fuller, St. Clair, Rudd.

Guests: Mather, Brannon, West, Redman, Aines.

1. Kearl moved approval of the minutes of the Executive Board meeting held at Chicago, Illinois, December 27-28, 1968. Seconded. Passed.
2. Kearl reported for the Tellers Committee that Hillman was elected as the President-Elect and Hildreth and Tweeten are to be Board Members.
3. Brannon reported for the Publicity Committee.
4. Mather reported for the Employment Committee.
5. Redman reported for the Local Arrangements Committee. Among other things, he indicated that the meetings were getting bigger and more complex and presented major problems which must be considered.
6. Hathaway moved that the President write a letter to Miss Hanly expressing appreciation for her efforts and service in connection with the meetings. Seconded. Passed.
7. The matter of private companies or other groups requesting the Local Arrangements Committee to make arrangements for such things as meetings and luncheons at the time of or associated with the annual meetings was considered. Hathaway suggested that arrangements be permitted but that a fee be charged for the services. Breimyer indicated that a committee has been appointed to consider guide lines for the host institution in the conducting of the annual meetings and is to report to the Executive Board at its winter meeting.
8. Breimyer reported for the Audit Committee. Hathaway moved authorization for the expenditure of funds for a CPA audit in connection with the transfer of the office of Secretary-Treasurer at the close of 1969. Seconded. Passed.
9. Kearl presented the Secretary-Treasurer's report. Hathaway moved approval as presented. Seconded. Passed.
10. Kearl presented the Investment Committee report.
11. There was a discussion of the change-over of the office and the date of change of membership on the Board. One suggestion was that the new officers and Board take over at the first of the year and that the Constitution be so amended. Dunbar moved that, in accordance with the Constitution, it should be understood that the President and other elected officers of the Board should serve for the year beginning with the adjournment of the annual meeting and have responsibility for the affairs of the Association through the next annual meeting. Seconded.

    Bishop moved that the newly elected Board Members be invited to attend and participate in the meetings of the Executive Board. Seconded. Passed.
12. The Montana meeting deficit was discussed but action was deferred.

13. Dunbar moved that travel expenses for Redman and his secretary be approved in connection with the move of the office of Secretary-Treasurer. Seconded. Passed.
14. Breimyer reported on the membership and operation of the committees for the 1968-69 year and made recommendations for modification of the committee structure.

    Dunbar moved that a resolution should be presented to the membership to delete the standing committee for "Relations With Other Professional Organizations" and that the functions be transferred to other committees of the Association. Seconded. Passed.

    Hathaway moved that a new standing Committee on Economic Statistics be presented to the membership of the Association with the understanding that the present special joint ASA-AAEA Committee on Agricultural Statistics be a subcommittee of the standing committee. Seconded. Passed.

    Hathaway moved that the present special Committee on Professional Problems in International Research be renamed as the Committee for International Activities and that the chairman be a member of the standing Professional Activities Committee. Seconded. Passed.

    Hathaway moved that the Extension Affairs, Industry Affairs, and International Affairs be special committees of the Association, and that their chairmen, and the chairmen of such other committees as should be designated by the Executive Board, should be members of the standing Professional Activities Committee. Seconded. Passed.
15. Hathaway presented the tentative AAEA committee appointments as of this date.

The meeting recessed at 12:00 noon.

The meeting reconvened at 1:30 P.M.

Present:

Voting members: Breimyer, Hathaway, Butz, Toussaint, Wharton, Hillman, Bishop (Absent Southern).

Ex officio: Purnell, Kearl, Fuller, Godwin, St. Clair.

Guests: West, Aines, Abel, Day, Rudd, Redman, Stanton, Upchurch, True, Ackerman, Eley, Martin, Taylor, Boggs, Harl, Halcrow, Hildreth, Manuel.

16. Abel reported for the Literature Retrieval Committee. Plans are being made for the establishment of the American Agricultural Economics Documentation Center through the joint efforts of the NAL, ERS, SRS, and AAEA. NAL, SRS, and ERS are to be responsible for the financing and the work of the Documentation Center and will prepare a tape of the bibliographic information. This tape can be obtained by AAEA for publication. A memorandum of understanding is being drawn up by the groups indicating the responsibilities. It was suggested that AAEA should appoint a separate person to work with the governmental agencies, to help coordinate the efforts and to handle the publication of the bibliography. This bibliographical editor and a committee to work with him would obtain feedback from the membership and others and, by close contact with the persons operating the Documentation Center, help to make the materials collected and the method of publication more effective and more in line with needs.

Hillman moved the appointment of a Bibliographical Editor and a Council to supervise the publication. Seconded. Passed.

Hathaway moved that the Executive Board go on record in favor of signing a memorandum of agreement with the NAL, ERS, and SRS and AAEA including a commitment to publish. Seconded. Passed.

Purnell indicated that CAES was interested in cooperating in connection with the Documentation Center and the bibliographical publication.

17. Martin reported for the Postwar Review Committee. The committee has met and revised the original outline of review articles and has given consideration to individuals who might be requested to write parts of the review series.
18. Boggs reported the activities of the Student Affairs Committee.
19. Harl presented a proposal for a change in the Association Bylaws to provide for a Student Section of the AAEA.

    Hathaway moved that the suggestions made by Harl be adopted as Article 13 of the Bylaws and that present Article 13 be redesignated as Article 14. Seconded. Passed.
20. West reported the activities of the Membership Committee.
21. Kearl reported the activities of the Sustaining Membership Committee.
22. Hildreth reported the activities of the Professional Activities Committee.

    Bishop moved that recommendation number one of the report be adopted. That recommendation is: That the Association adopt a position of interest in involvement with the Division of Behavioral Sciences. Seconded. Passed.

    Bishop moved that a visiting lecturer program be approved as one of the activities of the committee and that an ad hoc committee be appointed to initiate the program. Where self-funding, the program is to be started immediately and the committee is to bring to the Board proposals involving expansion of the program. Seconded. Passed.

    Hathaway moved that the Association accept the recommendation of the committee, that the President of the Association appoint a small committee of members to work with a professional writer in preparing copy for a potential national brochure on career opportunities in agricultural economics, and that travel funds be approved for not more than two meetings of this committee. The brochure will describe professional careers based on academic training in agricultural economics. Seconded. Passed.
23. Aines reported for the Industry Committee. Among other things, he indicated that the listing in the next Handbook-Directory should be changed to more adequately accommodate the industrial sector of the Association.
24. Halcrow reported as the representative of the Association to the NBER. He indicated some of the changes in the direction of the research of the National Bureau of Economic Research. It was suggested that he present a discussion of the research activities in an article for the membership to be published in the *AJAE*, and that there be a conference with NBER personnel at the winter meetings to discuss research needs of agricultural economics which might be relayed to the NBER directors.
25. Manuel reported on the Contributed Papers Committee activities.

Hillman moved adjournment of the meeting at 5:30 P.M., August 16, 1969.

The meeting was called to order by President Breimyer at 9:00 A.M., August 17, 1969.

Present:

Voting members: Hathaway, Breimyer, Bishop, Hillman, Dunbar, Wharton, Toussaint, Butz (Absent Southern).

Ex officio: Kearl, Fuller, Godwin, St. Clair.

Guests: Hildreth, Tweeten, Redman, Aines, Abel, Ackerman, Castle, True, Eley, McKinsey, Ruttan, Day, McConnen.

26. McKinsey, general chairman of the 1970 annual meetings to be held at the University of Missouri, reported on local arrangements.
27. Breimyer reported on the plans and problems in connection with the arrangements and location of future annual meetings.
28. Breimyer announced the request of IAAE for $5,000 for travel grants to the international meetings. The matter was set aside until later.
29. Breimyer reported that the Richard Abel Company had requested permission to reproduce AAEA sponsored publications. Hathaway moved that the President be authorized to permit the reproduction of official publications of the Association, with any royalties therefrom accruing to the Association. Seconded. Passed.
30. Breimyer raised the question of exhibits at the annual meeting. The matter is to be considered by the ad hoc committee which is to study annual meetings problems and policies.
31. Breimyer announced that there had been questions raised as to the three-year limit for junior members. This has previously been discussed several times. No action was taken.
32. Ackerman announced that three men had been elected Fellows of the Association.
33. Ackerman reported the activities of the ASA-AAEA joint statistical committee. The committee has felt that it should serve in more than an advisory capacity and that it should have a program of its own. Efforts will be made to move in this direction.
34. Ackerman reported on his activities as the AAEA representative to the Census Advisory Committee.
35. Fuller reported the activities of the Editor. He indicated that, in accordance with past policy established in 1961, papers which have been presented at the WAEA meetings and are subsequently submitted for publication in the *American Journal of Agricultural Economics* will be considered on their merit as articles of the *AJAE* and will be subjected to the usual review. Gerald Dean will serve as a second associate editor of the *AJAE*. Fuller indicated that he had contacted the principal printers of journals to obtain quotations for printing the *AJAE* and feels that there is no evidence that the Association can save money by changing printers. Savings can be made by changing the style and size of the journal, the cover paper, and the size and style of the type. Redman reported that his contact in Lousiville indicated similar conclusions. Fuller proposed that we continue to have the George Banta Company, Inc., print the *American Journal of Agricultural Economics* but that we shift to a 7″ by 10″ double column size, change the cover, and change the type styles in order to have easier composition at the printers. He also proposed that we stay with the present type

of paper. He further proposed that the American Bibliography of Agricultural Economics be published in the same size publication. Bishop moved that the proposals be accepted. Seconded. Passed.

The changes are to occur with Volume 52, February 1970. The November and December issues of 1969 are to be the same size as the present journal but under the new contract as proposed by the George Banta Company, Inc.

There was discussion of coordinating the publication of articles printed in the *AJAE* and papers presented at the annual meetings. This would be an effort both to improve the *AJAE* and to reduce printing costs.

Wharton moved that arrangements be made for the Editor to be informed as to the main theme of the meetings, in order that he can obtain or refer papers to the President for use in the meetings. Further, that the Proceedings issue be retained but that the full text will be printed only for such articles as the Presidential Address, major papers as determined by the President and Editor, and reports and minutes. Other papers are not to be printed in total but are to be submitted and printed as abstracts. There is to be no barrier in later submitting these papers to the *American Journal of Agricultural Economics* for publication, in which case they would be subjected to the usual review procedure. The details and procedures are to be worked out and reported upon at the winter meetings. Seconded. Passed.

36. Kearl presented information regarding a proposal for publishing a Handbook-Directory. Hathaway moved that items 2-5 of the report of the Handbook-Directory Committee published in Volume 49, No, 5 of the JFE be implemented for the publication of a Handbook-Directory in 1971. Seconded. Passed.

    A committee is to be appointed to arrange for the publication of this issue.

37. Kearl presented the budgetary problems of the Association.

    Dunbar moved that a charge of $5.00 be made for each back issue ten years of age and under and $10.00 for each back issue over ten years of age. Seconded. Passed.

    Hathaway moved that the present reprint prices continue to remain for the November and December issues and that the matter be considered at the December meetings for future prices of reprints. Seconded. Passed.

    Hillman moved that the advertising prices be changed per the recommendation for the November and December issues and be revised at the December meeting to consider new publication and costs. Seconded. Passed.

The meeting recessed at 12:00 noon.

The meeting reconvened at 1:30 P.M.

Present:

Voting members: Breimyer, Hathaway, Butz, Hillman, Toussaint, Wharton, Dunbar (Absent Southern).

Ex officio: Kearl, Fuller, St. Clair, Godwin, Purnell.

Guests: Ruttan, Timm, Castle, Aines, Tweeten, Hildreth, True, Abel, Eley, McConnen, Ackerman, Sinclair, Trelogan, Schmedemann, Redman, Manning, Hawkins, Derr, Rudd, Halcrow, Wills, Tefertiller.

38. McConnen reported on the finances of the Montana meeting. Unusual expenses due to rain and other things resulted in unanticipated expenditures and caused meetings deficit.

    Dunbar moved that AAEA allow Montana State University to keep the $1,000 advanced by the Association and close the books. Seconded. Passed.

39. Ruttan reported for the International Activities Committee.

    Hathaway moved that the Association appropriate $5,000 for travel grants for young men of the Association and that a committee of the American Agricultural Economics Association and the U.S. Council of the International Agricultural Economics Association be appointed to name the persons to receive the travel grants. Seconded. Passed.
40. Toussaint moved that two copies of the *American Bibliography of Agricultural Economics* be distributed to all members and subscribers without charge and that an annual charge of $10.00 be made for institutions and $3.00 for individual subscribers. Seconded. Passed.
41. Hathaway moved that the American Agricultural Economics Association rates be changed to $25.00 for subscriptions to the *American Journal of Agricultural Economics*, $15.00 per year regular Association dues, and $5.00 per year junior member dues. Seconded. Passed.

    In accordance with the Constitution, the matter of the dues is to be presented to the membership for approval at the annual meeting.
42. Dunbar moved the approval of the 1969 budget as revised. Seconded. Passed.
43. Derr and Hathaway reported on the New York winter meetings arrangements.
44. Castle reported on the activities of the Awards Committee. Hillman moved acceptance of the report. Seconded. Passed.

    Toussaint moved that the rules of the contest be changed to allow the submission by a department of one Ph.D. thesis for each twelve Ph.D. candidates, and one M.S. thesis for each fifteen M.S. candidates. Seconded. Passed.

    Hathaway moved the recommendation number one, "That the number of extension awards be limited to one, unless there are more than ten entries," be approved. Seconded. Passed.
45. Future meeting places were discussed. Manning presented an invitation from the University of Alberta to hold the meetings at Edmonton, Alberta, in 1973. The meeting dates would be the second Wednesday in August. Wills presented an invitation from Southern Illinois University to hold the meetings at that institution in any year. Timm reported that Texas A&M University preferred to delay hosting the meetings until 1972 or 1974. Tefertiller indicated that it would be difficult or impossible for the University of Florida to change from 1972, in view of the present commitments.

    Hillman moved that the Association meet at Southern Illinois University in 1971, the University of Florida in 1972, the University of Alberta in 1973 and Texas A&M University in 1974. Seconded. Passed.
46. McConnen reported for the ad hoc committee on the evaluation of the American Agricultural Economics Association employment service. He stated that there was no reason to discontinue the service, that it seemed to

be rendering acceptable service even though improvements could be made. Hathaway moved acceptance of the report. Seconded. Passed.

Redman reported that Loys Mather has been particularly interested in the employment activities and should be asked to report at the winter meetings on the possibility of the Association operating an employment service year-round.

47. Breimyer reported on the SIPPS proposal, and Hathaway moved that an individual be appointed to represent the Association in contacts with Mr. Ruggles in the matter of the SIPPS proposal and report to the Board.
48. Hillman moved to accept the report of the AAEA representative to the National Research Council and to continue having a representative to the Council. Seconded. Passed.
49. Dunbar moved that the Nominating Committee as named be approved with the addition of the USDA representative. Changes will be made as needed where persons have not been able to be contacted prior to meetings. Seconded. Passed.
50. The investment policy was discussed and the President was encouraged to make such changes in the Investment Committee as he feels are necessary to provide for continuity and yet constant reevaluation of the Association's position.
51. Dunbar moved the appointment of Redman as Secretary-Treasurer and Fuller as Editor of the *AJAE* as of January 1, 1970.
52. The question of joining other societies in hiring a lobbyist to work in Washington, D.C., was raised. No action was taken.
53. Hillman moved that, provided AAEA were invited to appoint a representative, Bishop be appointed as the AAEA representative to the Behavioral Science Commission if he will so serve. If Bishop declines to serve, the President is authorized to make some other arrangement.
54. Sinclair presented a request of the New England Agricultural Economics Council for joint membership with the AAEA and ex officio membership on the AAEA Board.

    Hathaway moved that the New England Agricultural Economics Council be accepted as a joint member and that the president of that Association be an ex officio member of the AAEA Board. Seconded. Passed.
55. The question of the procedures of the AAEA elections was raised and the possibility of some other methods was considered. Breimyer is to present a statement on the matter at the winter meeting of the Board.
56. Wharton is to present to the Board at the winter meeting a paper considering the matter of the Association taking stands on such things as legislation and the possibility of action which would enable the Association to be influential in bringing about changes which might seem desirable.

The meeting adjourned at 5:35 P.M.

MINUTES OF THE ANNUAL BUSINESS MEETING

Lexington, Kentucky, August 19, 1969

Meeting called to order by President Breimyer at 10:35 A.M.

1. President Breimyer presented for approval the minutes of the annual business meeting held at Bozeman, Montana, August 20, 1968, as pub-

lished in the Proceedings issue of the *AJAE*. Upchurch moved approval. Seconded. Passed.

2. Breimyer presented the annual report of the President.
3. Kearl presented the Investment Committee report for the fiscal year January 1 through December 31, 1968.
4. Kearl presented the Secretary-Treasurer's report for the fiscal year January 1 through December 31, 1968.
5. Breimyer presented the report of the Audit Committee.
6. Hildreth presented the resolution thanking Kearl for service to the Association as Secretary-Treasurer. Seconded. Passed.
7. Breimyer reported the actions of the Executive Board. These include: (a) formalizing the undergraduate student organization activities by adopting AAEA enabling bylaws; (b) approval of the Professional Activities Committee proposal for a visiting lecturer program and the publication of a career opportunities brochure; (c) approval of a change in the size and style of the *American Journal of Agricultural Economics* and a change in the Proceedings issue to print major papers in total and other papers in abstract form; (d) a change in the policy of accepting contributed papers which would enable these to be integrated more completely into the annual meetings program; (e) approval of plans to go ahead with the publication of a Handbook-Directory in 1971; (f) approval of a grant of $5,000 for travel grants for young agricultural economists to attend the international meetings in Russia; (g) approval for the publication early in 1970 of the *American Bibliography of Agricultural Economics* with the first two issues to be sent to all members and subscribers and an annual subscription rate of $10.00 for libraries and institutions and $3.00 for members; (h) a change in the awards program so that there would be two extension awards only if there were ten or more entries, otherwise there would be only one award given; also, departments are to be permitted to submit one Ph.D. thesis for each twelve Ph.D. students and one M.S. thesis for each fifteen M.S. candidates; (i) a decision to continue to have the employment service; (j) approval of the appointment of Varden Fuller as the Editor and John Redman as the Secretary-Treasurer effective January 1, 1970; (k) a decision to hold the annual meetings at the University of Missouri in 1970, at Southern Illinois University in 1971, at the University of Florida in 1972, at the University of Alberta in 1973 and at Texas A&M University in 1974; (l) approval of the New England Agricultural Economics Council as a joint member with the American Agricultural Economics Association, along with the Western Agricultural Economics Association, the Canadian Agricultural Economics Society, and the Southern Agricultural Economics Association.
8. Dunbar moved the following changes be made in the standing committees structure: delete the "Committee on Relations With Other Professional Organizations" and add a "Committee on Economic Statistics." Seconded. Passed.
9. Fuller reported the activities of the Editor. He announced that the JOURNAL would be changed in size to a 7″ by 10″ with two columns. There would also be a change in the type and the size of the type. He announced the appointment of Gerald Dean as an Associate Editor.
10. Hathaway discussed plans for integrating the *American Journal of Agricultural Economics* articles and the annual meeting program. He indicated

that the Presidential Address, the major papers, minutes and reports, and abstracts of other papers would be printed in the Proceedings issue.

11. Kearl presented a budget for 1970 for consideration by the membership.
12. Hathaway moved, with recommendation of the Executive Board, that the subscription rate for the *American Journal of Agricultural Economics* be set at $25.00, regular membership dues at $15.00, and junior membership dues at $5.00. Seconded. Passed.
13. Kohls raised a question as to the endowment fund policy.
14. Hillman presented a resolution thanking the University of Kentucky for hosting the meetings. Seconded. Passed.
15. Hathaway announced that (a) the December meetings will be held in New York City, December 27-30, 1969; (b) the chairman of the Nominating Committee is Harold Breimyer; (c) the Executive Board will appreciate receiving nominations for Fellows; and (d) the next meeting of the Association will be at the University of Missouri and will be held one week earlier than normal.

The meeting adjourned at 12:00 noon.

STATEMENT OF OWNERSHIP, MANAGEMENT AND CIRCULATION
(Act. of October 23, 1962; Section 4369, Title 39, United States Code)

1. Date of filing: September 29, 1969
2. Title of publication: American Journal of Agricultural Economics
3. Frequency of issue: Quarterly and December Proceedings Issue (February, May, August, November, December)
4. Location of known office of publication: Warren Hall, Cornell University, Ithaca, New York 14850
5. Location of headquarters or general business office: Warren Hall, Cornell University, Ithaca, New York 14850
6. Name and addresses of publisher, editor: American Agricultural Economics Association, Warren Hall, Cornell University, Ithaca, New York 14850. Editor: Varden Fuller, Dept. of Agricultural Economics, University of California, Berkeley, Calif. 94720
7. Owner: American Agricultural Economics Association, Warren Hall, Cornell University, Ithaca, New York 14850
8. Bondholders, mortgagees, and other security holders: none
9. Nonprofit organization: Status unchanged during preceding 12 months
10. The following circulation figures are provided for (a) the average number of copies of each issue during the preceding 12 months and (b) the single issue nearest to filing date:

Total number of copies printed	(a) 6,550	(b) 6,550
Circulation:		
Sales through dealers, carriers, etc.	(a) none	(b) none
Mail subscriptions	(a) 5,897	(b) 5,897
Total paid circulation	(a) 5,897	(b) 5,897
Free distribution	(a) 3	(b) 3
Total distribution	(a) 5,900	(b) 5,900
Office use, left-over, inventory balance, etc.	(a) 650	(b) 650
Total	(a) 6,550	(b) 6,550

I certify that the statements made above are correct and complete.

(Signed) C. D. Kearl
Secretary-Treasurer

AMENDMENT OF BYLAWS TO PROVIDE FOR STUDENT SECTION

Article XIII

Student Section

Section 1. *Authority for Student Section.* There is hereby created an organization within the Association to be known as the Student Section—American Agricultural Economics Association (hereinafter referred to as the SS-AAEA). The SS-AAEA shall function pursuant to a constitution which shall be developed initially by the SS-AAEA or a committee thereof, approved by a two-thirds vote of the SS-AAEA members present and voting at a meeting of the SS-AAEA at which a quorum is present, and then submitted to the Executive Board of the Association for approval. For purposes of this section, representation from at least twenty percent (20%) of the chartered chapters shall constitute a quorum. Amendments to the constitution of the SS-AAEA shall likewise be submitted to a vote of the members of the SS-AAEA under the voting and quorum rules hereinbefore specified and then submitted to the Executive Board of the Association for approval. The constitution of the SS-AAEA may provide for a statement of purposes, membership rules consistent with the Bylaws of the Association, selection of officers, election of a governing board of not more than seven (7) members in addition to the officers, duties of officers and the governing board, and provisions for meetings, voting (including apportionment of voting rights on the basis of chartered chapters for all matters except for approval of the initial constitution of the SS-AAEA or any amendments thereto which shall require a vote of the members as herein provided) and standing committees. The governing board of the SS-AAEA may develop bylaws containing internal governing rules for the SS-AAEA, which bylaws shall be submitted to the Student Affairs Committee of the Association for approval after the bylaws or amendments thereto have been approved by majority vote of the governing board.

Section 2. *Chartering of local chapters.* Any Department of Agricultural Economics, Department of Economics having programs of undergraduate study in agricultural economics or agricultural business, or any college or university or division thereof having programs of undergraduate study in agricultural economics or agricultural business may make application to the Student Affairs Committee of the Association for the creation of a chapter of the SS-AAEA. Upon making such application, fulfilling requirements imposed by the Student Affairs Committee and paying a charter fee of five dollars ($5), such chapter shall be created by issuance of a charter by the Student Affairs Committee, signed by the chairman of such Committee, the president of the Association, a director of the Association appointed by the president of the Association as a liaison member of the Student Affairs Committee, and the president of the SS-AAEA. Charters shall be issued initially for a term of five years and may be renewed for successive terms of five years each upon filing an application for renewal and payment of a renewal fee of five dollars ($5) for each such renewal. For chapters chartered prior to January 1, 1965, such charters shall be deemed to expire on January 1, 1970, unless application for renewal is filed and renewal fee is paid prior to said date. Payments for original and renewal charter fees shall be made payable to the treasurer of the SS-AAEA and shall be transmitted to the chairman of the Student Affairs Committee who shall, upon approval and issuance of the charter, forward such payments to the treasurer of the SS-AAEA.

Section 3. *Membership.* Any undergraduate student majoring or minoring in agricultural economics, agricultural business, or other curricula within or administered by a Department of Economics or Agricultural Economics in a college or university, or any member of a locally chartered chapter as hereinbefore provided, may become a member of the SS-AAEA. Members of a duly chartered local chapter shall be deemed automatically to be members of the SS-AAEA by virtue of membership in the local chapter. Membership certificates may be purchased by local chapter organizations from the SS-AAEA. An individual who is otherwise qualified for membership but who is not a member of a chartered chapter may become a member of the SS-AAEA by filing application with the treasurer of the SS-AAEA. Membership certificates shall bear the seal of the Association which shall be applied by the chairman of the Student Affairs Committee or his designated representative. Membership in the SS-AAEA shall not be considered a condition precedent to participation in events of the SS-AAEA, nor shall such membership be considered an eligibility requirement for awards given by the Association.

Section 4. *Accountability of funds.* All charter fees and other funds generated by the SS-AAEA shall be made payable to the treasurer of the SS-AAEA and transmitted to the treasurer of the SS-AAEA for redecoration and consolidation, and then forwarded to the treasurer of the Association for credit on the books of account of the Association in such account or accounts in the name of the SS-AAEA as shall be deemed advisable by the treasurer of the Association. The treasurer of the SS-AAEA shall be bonded to an amount of at least two thousand dollars ($2,000) by a general fiduciary bond. All payments from funds of the SS-AAEA shall be by check drawn by the treasurer of the Association as drawer upon request by the treasurer of the SS-AAEA, which request shall be countersigned by the chairman of the Student Affairs Committee of the Association or his designated representative. The SS-AAEA shall prepare a budget each year with the budget submitted to the Student Affairs Committee for approval prior to the beginning of the accounting period involved.

Section 5. *Role and duties of the Student Affairs Committee.* The Student Affairs Committee of the Association shall be responsible for working with and coordinating activities of the SS-AAEA as an integral part of the Association as a professional organization; organizing and conducting suitable and appropriate procedures or contests leading to the selection of recipients for undergraduate debate, undergraduate public speaking and undergraduate essay awards; working with the Awards Committee in presenting such awards; encouraging, supervising and approving the chartering of local chapters of the SS-AAEA; approving bylaws of the governing body of the SS-AAEA and all amendments thereto; approving expenditures from SS-AAEA funds; assisting the officers and governing board of the SS-AAEA in preparation of an annual budget: approving the annual budget of the SS-AAEA; providing advice and counsel to the officers, governing board and committees of the SS-AAEA; communicating with and making recommendations to the Executive Board of the Association regarding the affairs and programs of the SS-AAEA; assisting in program planning for SS-AAEA meetings; facilitating the organization and conduct of regional and national meetings in furtherance of the purposes of the SS-AAEA; and such other duties as the Executive Board of the Association may assign.

FORMAT OF THE 1970 ANNUAL MEETING

Some variations in programming will be tried for the next annual meeting. These will include an effort to utilize more of the self-initiated scholarship that regularly is submitted to *AJAE* as bases for discussions at the annual meeting. The Editor will keep me informed of the flow of manuscripts that have been reviewed and accepted for publication in the JOURNAL. Insofar as these papers offer subject matter that can be integrated into the annual meeting program, I plan to invite the authors to summarize and discuss their papers at the annual meeting. This will apply to papers that have already been published in issues of the JOURNAL preceding the annual meeting and to those accepted for publication in later issues.

To the extent that the thematic design for the annual meeting needs presentation of supplementary topics, I will expect to invite appropriate papers. However, these invited papers will not be automatically published as in the past. Authors of invited papers may, at their option, present manuscripts based on their invited papers for review and possible publication in the JOURNAL in the same manner as others seeking publication in the February, May, August, and November issues.

The proceedings issue (December) will contain abstracts of all papers presented and discussed at the annual meeting, regardless of whether an article has already been published or accepted for publication. As heretofore, the December issue will also contain the Presidential Address, the invited general session papers, committee reports, and Association business.

For the proceedings issue, abstracts can be longer (maximum 250 words) than for regular articles (these are having to be restricted to 100 words to qualify for the *Journal of Economic Literature*).

DALE E. HATHAWAY, *President*

INDEX TO VOLUME 51

1969

SUBJECTS

Agricultural Economics, General

- An Aggregate Model of Agriculture—Empirical Estimates and Some Policy Implications, 71
- Characteristics and Salaries of Agricultural Economists, 903
- Economics of Agricultural Economics (The), 1011
- A Few Comments from the Editors—In Response and Otherwise, 702
- A Future for "Agricultural Economics"? 1027
- International Encyclopedia of the Social Sciences: A Review Article (The), 268
- On Institutional Obsolescence and Innovation—Background for Professional Dialogue on Public Policy, 245
- Our Journal—A Viewpoint, 701
- Role of the Farm Foundation in Agricultural Economics (The), 370
- Unseen—and Unfeeling—Hand (The), 952

Agricultural Policy

- Theories Explaining the Persistence of Low Resources Returns in a Growing Farm Economy, 798

United States

- An Analysis of the 1964 Wheat Option, 100
- A Basic Framework for Policy Education, 1357
- Government Payments and the Distribution of Income in Agriculture, 1520
- Long-Term Versus Short-Term Land Retirement, 1524
- Payment Limitations: Effect on Supply Adjustment and Income Distribution, 1233
- Payment Limitation: Pros and Cons as Seen by Farm Organizations, 1234
- Payment Limitation: The Economic and Political Feasibility, 1237
- Pure Theory of Government Aid to Agriculture (The), 1511

Foreign

- Some Implications of the EEC's Agricultural Price Policy, 279

Commodities: Supply, Demand, Prices

Livestock and Livestock Products

- A New Look at Demand Analysis for Beef: Comment and Reply, 947
- An Analysis of Daily Fluctuations in the Hog Economy, 849
- Cash-Futures Price Relationships for Live Beef Cattle, 26

Dairy Products

- Consumer Attitudes Towards Milk Substitutes, 1149
- Consumer Preference for "Imitation" Milk Beverages, 1637
- Criteria for Defining Federal Milk Order Market Areas, 1138
- Federal Milk Marketing Order Provisions: Effects on Producer Prices and Intermarket Price Relationships, 625
- Milk Production and Utilization in the East, 964
- Predicting Aggregate Milk Production: An Empirical Study, 642
- Pricing Milk in Federal Order Markets, 1506

Field Crops

- Caloric Cost of Rice and Wheat Programs, 962
- Factors Associated with Variation in the Aggregate Yield of New Zealand Wheat (1918-1967), 866

Fruits and Vegetables

- Allocation of Florida Orange Production Among Alternative Product Forms and Market Sectors, 1134
- Consumer Knowledge for Sovereignty: Apples, 1247

Other

- Note on the U.S. Demand for Coffee, 912
- U.S. Import Demand for Green Coffee by Variety: Comment and Reply, 926
